THE prevalence of the Potato disease this year will inevitably again bring to the front the oft-repeated discussion upon the best times for planting and lifting Potatoes. The question of planting is just now a little out of date, and can hardly afford a useful topic for discussion at any time, for the simple reason that it must largely be governed by the season, soil, climate, and chiefly by the experience of the planter, so that whilst in some soils and situations one may with ease and safety plant in March, another dare not attempt to plant until perhaps the end of April. The question as to the best time for lifting is practically governed by the action of the disease. If there were none it would not matter, except for other cropping, how long the produce remained in the soil; but as the disease is so prevalent the question is, will early lifting save the crop? If we could lift our Potatoes before the disease appeared in the haulm no doubt they would be safe, but this year, as in nearly all previous years, the disease has appeared so early that even the earliest kinds, such as Early Rose, Ashleaf Kidney, Early Market, &c., have been in the full vigour of growth and the tubers immature. To lift such as these to store for a long period of consumption would be a mistake; the tubers would not keep, and would soon become totally unfit for food. We have yet no kind that will ripen as a good crop, or, indeed, any crop in three months, which is, at the most, all the possible growing season that our climate allows, as the disease is usually in full vigour early in July, and, under the most favourable conditions, April is rarely a month that will permit the Potato plant to grow in the open air without danger from its first enemy—frost. No sort, however early, that we at present have, will therefore give us by the earliest lifting when matured immunity from the disease.

Dealing, therefore, with such sorts as we have, and knowing that no more growth can take place after the haulm has become largely affected by the fungus, the point for decision is, does immediate and early lifting save the crop or any large proportion of it as compared with the produce left sound in the ground after all those affected have decayed? My own experience is a large one, and I must say that I have never yet found any gain resulting from early lifting, as the very earliest-lifted stocks, got up as soon as possible after the disease had appeared, have always when stored for a few weeks shown as many diseased tubers and in a worse form than similar stocks left in the ground. Exposure to the air seems but to facilitate the action of the disease in the tuber, and, added to the inevitable disappointment, is the labour incidental to the picking over of large stocks of perhaps half-diseased Potatoes. I believe that any tubers left untouched by the fungus when the haulm is destroyed will remain sound and good in the soil as well or even better than out of it during the early autumn months, whilst any tubers ever so slightly affected will decay sooner or later, even if lifted with all possible speed.

In any case very early lifting can only be practised with moderate quantities, but where the stocks run into acres of soil and tons of produce the lifting becomes a matter of labour and time, and everything cannot be set aside even for Potato lifting. This season, amongst other difficulties, the weather has presented a formidable obstacle to the lifting of Potato stocks for long storing, as no one would attempt to lift a crop in rain and mud. Half a loaf is better than no bread; therefore I would allow the Potato crop to remain until the diseased tubers are apparent; the sound ones can then be stored. A. D.

THE POTATO CROP IN AMERICA.

EARLY Potatoes come in large quantities from the West Indies to the New York market, and when old Potatoes are very cheap large quantities are shipped there in return, the West Indian planter of course getting the advantage between high priced new ones and low priced old ones, the freight rate being very low in both cases. From May until the end of June most of our Potatoes come from Virginia; they are usually of very good quality, and are about one-third higher in price than old ones. About the beginning of July the crop begins to come in in quantity from Long Island. It has been very large and of excellent quality this year, so that prices have been low; this crop

consists nearly all of Early Rose, being a good cropper and of excellent quality. Early in August the Long Island crop is all marketed and the ground sown with Turnips. The principal supply next comes from New Jersey, but there are complaints of the crop being light, owing to the long continued dry weather. The winter supply comes chiefly from Maine and Nova Scotia, and is usually of very good quality. Large quantities are also brought by canal from the northern part of New York State; these are brought and stored before frost sets in, as it is difficult and expensive to ship Potatoes in the winter. The principal enemy to the crop is the Potato bug, but it is not looked at now as other than a necessary evil; about three dressings of Paris Green prevent any serious damage being done. I have used nearly two barrels of plaster and five pounds of Paris Green on two acres of Potatoes at a cost for material of 4 dols. 25 cents, and it costs about as much more in labour to apply the mixture. Many mix the poison in water, but, unless in special cases, the labour is thus much increased, although there is a saving of material.

JAS. TAPLIN.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Californian Curled Lettuce.—This is a useful summer variety of Lettuce, and, in addition to its being very good for salads, it is extremely pretty, the leaves, which are of a yellowish green, being beautifully fringed. Therefore, as a central kitchen garden border crop, it is both useful and ornamental.—J. GROOM.

Potato Disease under Glass.—We have hitherto comforted ourselves with the idea that Potatoes grown under glass were at least safe from disease, but during this exceptional season we have convincing proof that this is not so, as several cases have come under my own observation of unmistakable Potato disease occurring under glass, and in Mr. Coleman's "Fruit Report" (p. 179) I observe that he mentions a severe attack of Potato disease under glass so early as March, a circumstance which shows that the malady is ever present with us, and that it only needs a proper seed-bed, so to speak, in which to develop itself. Tomatoes with us have been badly diseased under glass this year, both foliage and fruit being badly attacked, exactly as in the case of the Potato disease, and several other plants appear more or less affected by a fungus similar to that which affects the Potato. The air seems laden not only with moisture but with blights, and diseases have spread with alarming rapidity. Even the foliage of Parsnips is spotted and diseased, and Celery plants have been virulently attacked by the fly, even in the seed-bed, and denuded of their earliest leaves. The red sorts with us suffered more than the white kinds.—J. GROOM, *Linton*.

Early Cabbages.—To have these for use in spring they must be planted early in well-prepared soil in the most sheltered portion of the garden, when they will continue to grow all through the winter. Close to a wall or hedge from which cold winds are shut out and every ray of sunlight is enclosed is the place to select for a few rows, and the soil can scarcely be too full of manure for them, as a Cabbage planted in poor soil is the worst of all vegetables, but give it good treatment, and cut it tender and succulent, and it will be appreciated. As regards sorts, the late trial of Cabbages at Chiswick has rectified some of the synonymous terms, but a good selection of Enfield Market or the London Market Cabbage sown in the middle of July and planted out the first week in September will give as good Cabbages as can be grown.—J. G.

The Pea Crop.—This has been about the best garden crop of the year, for although late in filling their pods they have been unusually prolific and good. All kinds grow taller than usual owing to the occurrence of so much rain, and keep on bearing longer than they otherwise would have done. We have had the following old kinds in first-rate condition: viz., Sutton's Ringleader, Dickson's First and Best, Laxton's Alpha, William the First, Marvel (a new Pea of first-rate qualities), Little Wonder, Telephone (a kind with very large pods), Veitch's Perfection, Princess Royal, and Ne Plus Ultra for the latest crops. They are still extremely clean and free from maggots, and altogether Peas form one of the most satisfactory crops of 1879.—J. GROOM, *Linton*.

Diseased Tomatoes.—Our Tomato crop on the walls is nearly destroyed again this season by disease. We lost all our Tomatoes last year by the same malady before they were ripe, but this season they seem to be going before any fruit is set. The disease attacks them in the same manner as it does the Potato, beginning first with a small spot like mildew on the back of the leaf; that soon spreads, and the part affected becomes black. As soon as the blotch reaches the midrib the leaf droops, the leaf-stalk becomes striped and spotted, and finally the stems, when all begin to decay and smell just like diseased Potato haulm. Is there any remedy, or must we endure it as we do the Potato disease, with which I believe it to be identical?—W. WATSON, *Eaglehurst, Fawley, Hants*.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 26.

THE exhibits at this meeting were few, and consisted chiefly of cut flowers of Roses, Gladioli, Verbenas, Picotees, Phloxes, &c.

First-class Certificates were awarded as follows :

Encephalartos Friderici-Guilielmi (Bull).—A remarkably handsome Cycad with a huge trunk about 2 ft. high, terminated by a dense crown of leaves about 3 ft. long, with the petioles covered with a fulvous brown woolly substance. The leaves are divided into comb-like sharply-pointed divisions, the whole surface of the leaf being covered with a glaucous hue.

Carludovica Drudei (Bull).—A novelty in the way of *C. palmata*, but dwarfer, and the leaf-segments have a gracefully arching habit. It will, no doubt, form a highly decorative plant.

Kentia Wendlandi (Bull).—An elegant Palm, with pinnate leaves from 2 ft. to 3 ft. long, but having somewhat of a rigid habit.

Agapanthus umbellatus albus (Bull).—A desirable variety of an old garden favourite, differing from the type only in having pure white blossoms, and it is as equally easy to grow.

Gladiolus Electra, **T. S. Ware**, **Duke of Connaught**, **Samuel Jennings**, and **Duchess of Connaught** (Kelway & Sons).—All fine new varieties, and well deserving the distinction accorded to them.

Picotees Lady Rosebery and Sultana (Turner).—The former is a bright orange-red with dashes of a deeper shade, and the latter a pale sulphur of large size and good form.

Picotee Princess Beatrice (Turner).—A variety with yellow ground and red edges, pretty and distinct.

In addition to those enumerated above, Mr. Bull sent plants of the new Penanga Kullei, *Walliehia nana*, *Tradescantia multicolor*, *Agapanthus umbellatus fl.-pl.*, and a variety of *Weigela amabilis* bearing the name of *Looymansii aurea*. A panful of cut blooms of the gorgeous Tiger Flower (*Tigridia grandiflora*) was also shown by the same exhibitor, and a vote of thanks was accorded it.

Mr. J. S. Ware, Tottenham, sent cut blooms of the new beautiful *Montbretia Pottsi*, described in our columns last week.

A new *Gladiolus* named *Marie Lemoine*, similar to that certificated at the last meeting, was exhibited by Messrs. Veitch for M. Lemoine, Nancy. The parentage of this hybrid also is probably the same as that of the other shown previously.

The principal attraction of the meeting was centred in a magnificent collection of cut spikes of *Gladiolus*, all of which were, notwithstanding the unfavourable season, as near perfection as possible. The flower-spikes averaged from 1½ ft. to 2 ft. high, with flowers of large size and presenting a striking diversity of colour. The finest comprised *Jessica*, chiefly of a rosy hue; *Samuel Jennings*, bright scarlet with the under segment white; *A. F. Barron*, deep rich salmon tint; *T. S. Ware*, intense scarlet, large and dense spike; *Egyptian King*, a very distinct and deep rich plum colour; *Electra*, bright rosy-magenta, large flowers and spikes; *Duke of Connaught*, a splendid kind with flowers of brilliant crimson, mottled with a brighter shade. These, with several others shown, were Messrs. Kelway's seedlings this year, and were worthily awarded a gold medal.

Messrs. Perkins & Sons, Park Nurseries, Coventry, exhibited four boxes of cut Roses, consisting of a varied selection of the leading varieties in fine condition for the present time. A new seedling variety, *Henry W. Eaton*, was also shown by the same exhibitor. The flowers are of moderate size, good form, and brilliant crimson colour. A silver Banksian medal was voted to this collection.

From Mr. Charles Turner, Slough Nurseries, came a collection of cut blooms of *Picotees*, the most noteworthy of these being *Picotee Sultana* (self), with flowers of large size, and bright orange-red colour; *Lady Rosebery* (with pale sulphur flower), *Lightning*, *Lady Biddulph*, *Lady Aitchison*, and *Sir John Lambert* were also fine red-edged varieties. *Mrs. Colman*, *Flavius*, *Mrs. Purvis*, *Princess Beatrice*, and *Dove*, though exhibiting somewhat of a sameness in their colour, are nevertheless desirable varieties; *Cyprus*, *Sebastian*, and *Edith* are also pretty varieties. The whole strain received high commendation.

Mr. Cannell, Swanley, showed a superb collection of *Verbenas*, comprising nearly three dozen varieties. A selection of the best were—*Miss Matilda* with very large trusses of white and quaintly striped with violet; *Kentish Beauty*, a remarkably rich purple kind; *Neptune*, *Lord Leigh*, trusses; *Shakespeare*, splendid scarlet; *Lady Langlesbury*, white, with a broad purple stripe down the centre

of each petal; *E. Perkins*, white, with carmine centre; *Boule de Neige*, large trusses of pure white; *Marquis of Salisbury*, a rich clear violet; *Master R. Cannell*, of a lighter hue. A very fine unnamed seedling form was also in the same collection with white pips broadly margined with purple; a collection of *Phloxes*, *French Gold-laced Marigolds*, and a dozen flowers of *Hollyhocks* perfect in colour and form. To these a gold medal was awarded.

A small group of *Colens* was sent by Mr. Lloyd, Brookwood Asylum, Woking, and a similar contribution came from Messrs. Carter & Co., High Holborn, one of which named *Canary Bird* was remarkably distinct from the ordinary kinds.

From the Society's Gardens came a well grown group of *Celosias* and *Cockseombs*; also plants of the handsome *Abutilon Sellowianum marmoratum*, and the elegant *Reidia glaucescens*, a plant well deserving of more extended knowledge; also cut blooms of the pretty *Papaver umbrosum*, which somewhat resembles the common field Poppy (*P. Rhæas*), but is much superior on account of the distinct black blotches on each of the petals.

Messrs. F. & A. Smith, Dulwich, contributed a group of *Balsams*, of a choice *Camellia-flowered* strain; also a fine example of the graceful *Asparagus plumosus*, a greenhouse kind admirably adapted for cutting purposes.

Fruit.—On this occasion Messrs. J. Carter and Sons' prizes for single fruits of *Dell's Hybrid Melon* were competed for, but only five fruits were exhibited. The best came from Mr. T. Taylor, gardener to Mr. J. McIntosh, Duneevan, Oatlands Park; Mr. T. Jones, Elvetham Park, Winchfield, showed the next best; and the third prize was awarded to Mr. J. Bennett, Deepdene, Dorking. *Apple Gray's Seedling*, a handsome kind, was sent by the raiser, Mr. Gray, Brooke, Isle of Wight. Mr. J. Douglas sent *Apple Kerry Pippin*, and *Strawberry Pippin*, a handsome kind of moderate size.

Vegetables.—Mr. Culverwell, Thorpe Perrow, Bedale, sent *Seedling Pea Autumn Marrow*, a prolific bearer, with pods of unusually large size. Messrs. E. A. Webb & Sons, Stourbridge, sent samples of their new *Marrow Pea*. Messrs. J. Cook & Son, Weybridge, also sent a *seedling Pea*, *Cook's Conqueror*. Messrs. Hurst & Son, Leadenhall Street, contributed a dish of new *Mammoth Negro Beans*, with pods of large size—a prolific bearer. A first-class certificate was awarded to this variety.

CRYSTAL PALACE FRUIT SHOW.

AUGUST 28, 29, AND 30.

NOTWITHSTANDING the general lateness of the season, the date of the annual exhibition of fruit at the Crystal Palace was fixed quite a month earlier than that of the last and previous years, which necessarily resulted in a display far below the average, both in point of number and quality of the exhibits. Hardy fruits were especially poorly represented, and the long lines of Apples shown last year strikingly contrasted with the meagre display on this occasion. The classes for vegetables were withdrawn, as were also those for cut flowers. Several collections were, however, contributed, which considerably enhanced the attractiveness of the meeting. Amongst these the *Roses* from the Waltham Cross Nurseries and the superb group of *Gladioli* from Messrs. Kelway & Son, Langport, were the admiration of every one, and were worthily awarded extra prizes.

Collections of Fruit.—The competition for twelve dishes of distinct kinds, though by no means numerous, there being but three exhibitors, was closely contested. The premier collection was shown by Mr. Coleman, Eastnor Castle. It consisted of *Black Hamburg Grapes*, large in bunch and berry, and highly-finished *Muscats* of *Alexandria*, also good; *Pine-apples Prickly Cayenne* and *Charlotte Rothschild*, both heavy and well-formed fruits; *Melons Dr. Hogg* and *Golden Gem*; fine examples of *Royal George Peach* and *Pitmanston Nectarine*; *Bigarreau Napoleon Cherries*, *Peach Apricot*, *Kirke's Plum*, and *Brown Turkey Figs*. The next best collection came from Mr. Sage, Ashridge, the most noteworthy points in which were the *Royal George Peaches*, a heavy bunch of *Bananas*, and *Eastnor Castle Melon*. The other fruits shown were *Crown Bob Gooseberry*, *Hemskirk Apricot*, *Early Favourite Plum*, *Brown Turkey Figs*, *Él-ruge Nectarine*, *Bigarreau Cherries*, *Bellmore Hybrid Melon*, and *Muscats* of *Alexandria* and *Black Hamburg Grapes*.

Grapes.—In the class for ten distinct kinds there were but two exhibitors. The premier prize was taken by Mr. W. Elphinstone, Shipley Hall, Derby, whose collection comprised *Black Alicante*, *Gros Colman*, *Muscats* *Hamburg*, *Foster's White*, all of first-rate quality; *Golden Queen*, *Buckland Sweetwater*, *Muscats* of *Alexandria*, *Lady Downes*, and *Black Hamburg* scarcely so good. The other competitor was Mr. Bannerman, Blithfield, Rugeley, who had fine examples of *Black Prince*, *Trebbiano*, and *Gros Colman* amongst his collection. For three bunches of *Black Hamburgs* there were a

dozen exhibitors, the majority of whom showed excellent samples. The best came from Eastnor Castle Gardens, and were simply perfect in size of bunch and berry. The second prize set were quite equal in finish, but scarcely so large. Mr. Coleman was also the most successful of the two exhibitors in the class for Muscats of Alexandria, which were very fine examples of skilful culture, though lacking the bright amber tints attainable in favourable seasons. The first prize for Gros Colman was taken by not large bunches, but as regards size of berries and exquisite finish they left nothing to be desired. Two other sets were shown, which were also good. Of Madresfield Court Grapes the best were shown by Messrs. Peed & Sons, Roupell Park, Norwood. Though they did not excel in size the other two sets shown, they were much superior in point of finish. Some fine bunches gained first honours for Black Alicante, and were exhibited by Mr. H. Folkes, Hemel Hempstead. They were not extraordinarily large, but they were unusually fine in other points. There were three other exhibitors in the class. The class for black Grapes of any kind was more numerous represented, there being eight contributors. The best were shown by Mr. W. Elphinstone, Shipley Hall, Derby, who had moderately large bunches of Black Hamburgh, but scarcely so well coloured as they might have been. The next best came from Eastnor Castle, which were well-grown examples of Venn's Black Muscat. The first prize for white Grapes of any variety was taken by Mr. Folkes, Hemel Hempstead, with excellent bunches of Buckland Sweetwater. Foster's Seedling was also shown well for the second prize. There were five other exhibitors in this class. The heaviest bunch of black Hamburgs was shown by Mr. F. Jordan. It weighed 5 lb. 4 oz. The heaviest bunch of a white variety was one of Trebbiano, weighing 3 lb. 6 oz., shown by Mr. O. Goldsmith, Polesden Lacey, Dorking.

Pines.—These were but scantily represented, especially in the class for the Queen variety, there being but one contributor, and the fruit shown was not above the average size. Smooth Cayennes were shown well, and represented some heavy and well formed fruits. The best was shown by Mr. D. Wilson, Castle Hill, South Moulton, Devon, whose fruit weighed 6 lb. 10 oz. The other fruit came from Wycombe Abbey, and was also good. In the class for Pines of any variety the finest was shown from Eastnor Castle, and the next best from Mr. D. Wilson, both of which were the Charlotte Rothschild variety.

Peaches and Nectarines.—These were but scantily represented in all the classes. The first prize was awarded to the Alexandra Noblesse variety. But two exhibitors showed in the class for three dishes of Nectarines. The best came from Mr. Bannerman, who had Violette Grosse, Violette Hâtive, and Elruge. The class for single dishes contained some very good fruits. The best were shown from Ashridge Garden by Mr. Sage, who had admirable fruits of Royal; the second prize was taken by some fine fruits of Princess of Wales. Eight other dishes were also shown, and amongst them were fine examples of Princess of Wales, Violette Hâtive, and Grosse Mignonne. Seven dishes were shown in the class for Nectarines. Some excellent fruits were shown of the Pine-apple variety for the first place, and Stanwick for the second.

Melons.—About a dozen fruits were shown in the class for green-fleshed varieties. Mr. Sage was first with a fine fruit of Eastnor Castle, and a handsome fruit of the Squire was exhibited by Mr. Bailey, Shardeios, for the second place. The best scarlet-fleshed kind was Victory of Bristol, a beautifully netted variety, shown by Mr. Carmichael, Bury St Edmunds, and Mr. Coleman showed Dr. Hogg for the next prize. Seven other fruits were shown in this class.

Figs.—There was but one entry for three dishes of this fruit, and these were from Ashridge Gardens, consisting of Lec's Perpetual, Bourlissott Blanche, and Brown Turkey. Mr. Coleman showed the best single dish, consisting of well-grown fruits of Brown Turkey. The same variety also gained the second place. Two other dishes were shown.

Plums.—These were but poorly shown; only two exhibitors showed in the class for three dishes. The first prize was awarded to Golden Gage, Kirke's, and Emperor. The best Green Gages were shown from the Elvetham Park Gardens. Three dishes were shown.

Apples.—The poor display of these showed unmistakably the backwardness of the season, there being but a dozen dishes shown. The best three dishes came from the Convent Garden, Rochampton, and consisted of Irish Peach, Cellini Pippin, and Quarrendon.

Pears.—Only three dishes of these were shown, and these in inferior condition; the varieties were Green Chisel, Jargonelle, and Williams' Bon Chrétien.

Tomatoes.—The class for a collection containing twelve fruits of each kind was unrepresented. There were five dishes shown in the class for twelve fruits; the best consisted of excellent examples of Trophy, shown by Mr. J. Worthing, Chadwell Heath, Essex.

Cucumbers.—The best brace of the white-spined variety was exhibited by Mr. J. Davy, Streatham, for a handsome seedling kind. Six other contributions were displayed, amongst which were excellent fruits of the Olive, Duke of Connaught, and Duke of Edinburgh kinds. The finest brace of black-spined kind were Telegraph, shown by Mr. Williamson, Dulwich. There were four exhibitors in this class.

Miscellaneous Class.—An extra prize was deservedly awarded to Mr. D. Wilson, gardener to Earl Fortescue, Castle Hill, North Devon, for half-a-dozen splendid fruits of Smooth Cayenne Pine-apples, all of which were admirable examples of skilful culture. Mr. H. Smith, Leeds, Yorkshire, sent four dishes of Gooseberries of large size, and Mr. C. Osman, Sutton, a seedling scarlet-flesh Melon. Mr. T. Laxton, Bedford, exhibited samples of Peas Laxton's Marvel, Laxton's Improved Omega, and Laxton's Improved Connoisseur; also pods of an unusually large variety of Broad Beans.

Flowers, &c.—A tastefully-arranged group of plants was contributed by Messrs. J. Laing & Co., Forest Hill, consisting chiefly of Palms, Ferns, Dracenas, Caladiums and other Aroids, Crotons, Coleus, and other fine-foliaged plants, which were enlivened by flowering plants of Begonias, Phloxes, &c. Messrs. Kelway & Son, Langport, exhibited a splendid collection of Gladioli, comprising about eight dozen spikes remarkable both for the large size, perfect form, and great diversity of colour in their flowers. A dozen boxes of cut Roses were shown from the Waltham Cross Nurseries, which, considering the untoward state of the weather, were in fine condition; the Tea Roses were especially noteworthy. A group of ornamental Grasses was shown by Messrs. Hooper & Co., Covent Garden; the bright hues of the dyed flowers and Grass were very gay. A group of Succulents, &c., including a collection of small plants in miniature, were contributed by Mr. Boller, Kensal Town.

First-class Certificates were awarded to Messrs. Kelway & Son, Langport, for the following Gladioli:

Lord W. Beresford.—Large spike; flowers amaranth, shaded with purple-lilac and streaked with white.

James Douglas.—A splendid variety with flowers rosy-lilac, dashed with crimson and white.

Jessica.—A fine large flower; white, tinged with lilac; crimson throat, and yellow blotch on lower petal.

Duke of Connaught.—Flowers deep cerise, mottled with a lighter shade, and veined with white.

Duchess of Connaught.—White blossoms shaded with purple, rich violet-purple throat.

A list of awards will be found in our advertising columns.

ANSWERS TO CORRESPONDENTS.

Pear Cordons.—I have some planted four years ago, which I have each year summer-pinned to four and then to two leaves, but the successive year's growths have in some instances reached a length of 12 in. or 15 in., and the inner portion (nearest the stem) is becoming bare of shoots and leaves. How must I proceed? and ought I to have winter pruned them each year to keep them within bounds, and if so to what extent?—**Puzzled.** [Yes; partial winter pruning is an absolute necessity in order to prevent the accumulation of long naked spurs, for no matter how persistently the trees are summer-pinned, it is obvious that in time the spurs must get long and bare unless occasionally shortened back to within an inch or two of the main stem. We would advise you to shorten, at next winter's pruning, a fourth portion of these spurs, of course selecting those most bare of buds, and each year afterwards, selecting the next worst, till all have been removed. You need have no fear that new shoots will not be produced, for even if cut to a dormant eye or bud new growths are sure to appear, which stop or pinch as before.—W. W.]

Wall Plants.—I have a wall facing the east on one side of my flower garden now covered with Pear trees. These are worn out, and I want to cover the wall with evergreen shrubs that will grow pretty close to it, and so hide the brick-work. I may state that it is partially sheltered by a wall from the north, and evergreen shrubs and trees from the east. The trees are on the other side of the lawn about 30 yards off. What had I better plant? I do not want to use Ivy if I can get anything else. Would *Garrya elliptica* do on such an aspect, and does it cover well?—**H. D. P.** [There is nothing better than Ivy, of which there are several kinds differing more or less in the form of their leaves and rapidity of growth. Other plants suitable for the purpose are variegated *Euonymus*, *Evergreen Jasmines*, *Myrtles*, *Sulax mauritanicus*, *S. tannoides*, *Holbeilia latifolia*, &c.]

Names of Plants.—*Sub.*—1, *Spiraea arifolia*; 2, *Dentzia scabra*, fl.-pl.; 3, *Taxus adpressa*; 4, Cannot name without flowers; 5, *Spiraea callosa*; 6, *Berberis* (cannot name without flowers). *Alpha.*—*Spartanum africanum*. *F. N. K.*—*Poinciana Gilliesii*. *Northwoods.*—The Sweet Pea bloom sent is not uncommon, and may be found in almost every good strain. *N. R.*—1, *Gloriosa Plantii*; 2, 3, 4, varieties of *Achimenes*, which we cannot undertake to name; 5, *Lilium longiflorum*; 6, *L. chalcidonicum*. *R. T. K.*—1, *Tetrachlea hirsuta*; 2, *Roella ciliata*. *A. K.*—The yellow flower is *Calceolaria chelidonioides*, the other *Mertensia paniculata*. *Notts.*—1, *Oncidium cucullatum*; 2, *O. nubigenum*; 3, *Odontoglossum Lindleyanum*. *Alpha.*—1, *Godetia Whitneyi*; 2, *G. amena*; 3, *G. Lindleyana*; 4, *Gnothera frutescens*. *Mr. M.*—We are unable to ascertain correctly the names of the twigs of shrubs you send, but apparently they belong to the Himalayan *Lilae* (*Syringa Emodi*). *Dublin.*—1, *Gentiana gelida*; 2, *Monarda fistulosa*; 3, *Cireia Rutetiana*; 4, *Bartonia aurea*; 5, the Hop Hornbeam (*Ostrya vulgaris*). *M. E. T.*—*Hesperocordum lacteum*. *Devon.*—*Berberidopsis corallina*, a native of Chili.

"This is an art
Which does mend Nature : change it rather : but
THE ART ITSELF IS NATURE."—*Shakespeare.*

IN THE KENTISH FRUIT GARDENS.

As regards hardy fruits Kentish gardens have this year little to attract attention, for orchards from which in some years thousands of bushels of fruits have been sent to the London markets are this year almost fruitless, and it is only in a few gardens, such as that of Mr. Killick's, of Langley, to which our visit was specially made, that anything like even one-third of a crop can be found. The Hops, too, on which so many people in Kent depend, are this year a doubtful crop, being badly infested with mildew and "vermin," as the green and black fly are called. Mr. Killick, though owning a large extent of orchards for growing fruit for market, likewise devotes much time and space to the growth of dwarf Apple trees for the purpose of ascertaining which are the best kinds for the locality and also to provide fruit for show; and the same remarks also apply to Potatoes.

Apples.—In this locality Apples this year are a very scanty crop. I visited some of what are considered the best orchards round Maidstone and Langley, and only a few kinds of Apples were bearing anything like a crop; indeed 90 per cent. of the trees have no fruit on them at all. Mr. Killick has quite an exceptional crop, the reason being that he has but few kinds in any quantity, except those which he has proved for years to bear crops in all seasons, and with these kinds nearly all the old trees about the place are being grafted. The three sorts on which the most value is set are Warner's King, Tower of Glamis, and Stone's Apple or Lodington Seedling, the latter being without doubt the best and most profitable kind of Apple grown in Kent, for no matter how bad the season, this may always be depended upon to produce a crop. Its fruit is something like that of the well-known Keswick Codlin, but larger, and more highly coloured, and much firmer. It is fit for culinary purposes in August, and will keep good till the end of November. The tree makes but little growth each year. The original tree, comparatively a small one, is growing in a garden belonging to Mr. Skinner, where it has been planted at least thirty years, and it is stated to be only very little larger now than it was fifteen years ago. This tree is now bearing the best crop of Apples which we have anywhere seen this year—in fact such a crop as one would not expect to be surpassed in even the best of Apple seasons. Mr. Killick has hundreds of old trees cut back and grafted with this kind. Grafting is not performed here in the way in which it is generally done. In the first place the trees are not cut back into the old thick limbs, but only to supple wood the size of a broom handle. The rind only is opened to admit the graft, which soon "takes;" the old wound gets healed over, and few would detect that the tree had been grafted at all. In the second year after grafting a fairly good crop of fruit is obtained. After this, any shoots of the original kind which may spring from the old wood are kept cut off, and new life, as it were, is thus given to the tree.

Orchards.—The method of forming Apple orchards here is an excellent one. Land occupied by Hops is planted with Apple trees at suitable distances apart, and they make rapid growth. The Hops remain for three years or so; the ground is kept well cultivated for their sake, and when they are dug up the orchard is laid down in Grass, which is eaten off by sheep. By this means the ground is kept

manured, which induces the trees to grow and bear well. Orchards thus formed are considered the best and most profitable of any. The expense in forming them is trifling, whilst when once established they incur no further trouble. The trees, moreover, succeed better than those planted in land previously laid down to Grass, a fact clearly apparent here, where both plans have been tried.

Keeping Apples.—All those who have been in the habit of visiting the meetings of the Royal Horticultural Society at South Kensington, know in what excellent condition Mr. Killick has on many occasions exhibited collections of Apples even in the end of July. The method of preserving them in such a sound, fresh state is as simple as it is effective. An ordinary looking cupboard, placed in a cool room attached to one of the Hop kilns, is the place in which Apples are kept so well at Langley. Inside the cupboard are lattice-work shelves, on which the fruit is stored. The secret of success, however, lies in the following points being observed: Firstly, the fruit must be thoroughly sound and ripe when gathered from the trees; secondly, it must be laid out in an airy place to get thoroughly dry before it is stored; and thirdly, after it is placed in the cupboard—which, by the way, must be air-tight—no more light or air must at any time be admitted to it than is absolutely necessary. If required for show the Apples should be carefully taken out and packed at once in hampers or boxes, and, when returned, replaced in the cupboard without delay. By observing these rules any fairly good keeping Apple may be kept sound until the tree from which it was gathered affords a crop fit to gather the following year.

Choice dessert and new kitchen kinds are grown chiefly in the form of dwarf, pyramidal, or bush trees. They are planted some 10 ft. or 12 ft. apart each way, and the ground between them is well cultivated and cropped. Large numbers of fine Apples are obtained from them, even in such unfavourable seasons as the present. The kind bearing the best crops this year is Elington Seedling, a new sort, which ripens its fruit in September. It is a fresh yellowish-green looking Apple, very smooth and bright, and is considered to be in every way an excellent kind, and one which will eventually, on account of its hardness and heavy cropping property, be largely grown. Emperor Napoleon is another kind of great excellence; we noticed several trees of it bearing really good crops. Its fruit is of a bright red colour, and ripens early in September; indeed, it was eatable in the middle of August. It is a good flavoured kind and well worth extensive culture. Golden Spire is another good sort, and one which seldom fails to yield a crop of good fruit.

In the grounds of Mr. W. Skinner, who is well known as a successful exhibitor of Apples, and who owns what is considered to be one of the best, if not the best, Apple orchards in Kent, we found as a rule but a very scanty crop of fruit, and that in the case of trees generally noteworthy for their productiveness. One tree, however, of an unnamed sort, probably raised in the neighbourhood, proved an exception, for on it there were supposed to be about forty-five bushels of Apples. The tree, which is very handsome in shape, covers a space of not less than 140 ft. in circumference.

Plums.—Of the commoner kinds of Plums there are in some places fairly good crops; at Mr. Killick's they are bearing almost heavy crops. Crittenden Prolific or Cluster Damson, one of the best of Damsons, is grown by Mr. Killick in large quantities. It is, indeed, planted round every field near the hedgerows to form a shelter for other crops. On this Plum there are really good crops, which, for jam making, bring this season high prices. In plentiful Plum years, however, its value is considerably lower. This

Plum, which was raised in Kent many years ago, bears freely on the previous year's growth, and, on account of its extreme hardness, rapid growth, and good cropping propensity, trees of it in Kent may be counted by the thousand. A Plum known in the Kent market as the Violet Plum is also largely grown in this neighbourhood. It is the Violet Damask, a reddish-purple, medium sized Plum, not of the best quality. Mr. Killick is fast heading back all his trees of this and grafting them with Denyer's Victoria, or what is termed the Bush Plum, a kind somewhat like the Orleans, but rather smaller and firmer when ripe. It is an immense cropper, very hardy, and the fruit travels well; it is therefore of great value for market purposes. Trees of the Prune Damson, of which there are large quantities to be found here, are bearing this year very large crops; but although that is the case, it is a kind which Mr. Killick says he would never plant again, for notwithstanding the large crops which it produces, it seldom pays.

Cob Nuts.—Of these Mr. Killick has large crops. The trees, which are cup-shaped, are grown in the most exposed open spaces in some of the orchards. They are pruned rather hard in during winter in order to keep them in shape and within bounds; in August the young shoots are thinned out, and all the points are broken off in order to admit more light and air to the trees.

Of Pears nearly the only kind grown about here is the Hazel.
C. W. S.

THE ROOT PRUNING SEASON.

THE advantage of root-pruning upon fruit trees depends a good deal upon the season of the year in which it is performed. The work is often delayed in gardens through pressure of other duties till the winter is well advanced or nearly over, by which period root-pruning of out-door fruit trees would be better left undone. Root-pruning at midwinter, or later, will have the effect of checking over-luxuriance of course, but it also ruins the prospects of even a partial crop of fruit the season following, as the trees have not then the power of recouping themselves before growth commences. On the other hand when the pruning is done, say, in the autumn the mutilated roots have time to heal and partly re-establish themselves, thus lessening the check to the growing and bearing power of the tree while still effecting the object intended equally well. This, however, applies more particularly to trees that have been occasionally root-pruned before, and not to aged strong growing subjects that may never have been meddled with in that way. Root-prune the latter when we may, the check is likely to destroy the prospect of fruit for one season at least, but afterwards such trees make up for it. In cottage gardens and in orchards such neglected trees are most frequently seen. Planted originally in a good deep soil perhaps, they develop unusual vigour of branch and bear but indifferently. For all such, root-pruning is the cure and will speedily convert the trees to fruitfulness. Rash measures must not, however, be resorted to, nor do we wish it to be understood that mere barrenness in a tree is always a sign that root-pruning is needed; the signs of over-luxuriance either in a young or old tree cannot be mistaken. When the annual growths are long and thick, and the foliage green and broad, and neither are perfectly matured, then root-pruning is indicated. A trench should be cut round the trunk a few feet from the base and all roots projecting beyond that distance should be chopped off and the remainder laid bare for a bit towards the trunk until it is ascertained that none are left that are pushing down into the subsoil; then the roots should be covered over again, taking care to clear all mutilated points with the knife and lay the roots down regularly within 1 ft. or 2 ft. at most of the surface of the soil; much will depend upon the age of the trees and the depth of the roots. In no case should old or established trees be lifted entirely out of the ground, as the check may prove too much for them. In the case of such trees root-pruning may be performed any time between the beginning of September and the middle of November, but the earlier the better.

Turning to young or dwarf trees, whether standards or on walls, and which have been operated upon before, root-pruning should be done in September or October at the latest. Fruit trees that have been root-pruned regularly, say every three or four years, do not suffer any great check by the process if carefully managed. In the

course of time the roots get into a mop condition and become plentiful, and they can then be dealt with easier than when a tree has only a few strong roots and few fibres. Such trees should never, indeed, be allowed to become unfruitful if root-pruning is practised periodically. The check should be administered before the trees have completely got over the effects of the last pruning. Cutting a trench round the trunk, 3 ft. or 4 ft. away from it, and severing all the roots met with pushing beyond, and shoving the spade under the ball 12 in. or 18 in. all round, will be enough in nine cases out of ten, and will not check growth to the extent of causing it to drop its fruit the season following.

These remarks apply to all fruit trees more or less, but the operation of root-pruning requires to be performed with more care in some cases than others. Strong-growing Apples, Pears, Plums, or Cherries will stand pretty severe handling when in good health; but such things as Peaches and Nectarines need more gentle handling, as their roots are brittle and not so numerous. In the case of the latter the trench should be opened farther from the trunk, and each root should be carefully followed up as far as it is desired to go, and they should be laid down again in good, rich, but sharp soil, in order to induce fresh fibres along the bare roots. The Peach is a subject, however, tender as it is, that will oftener bear a crop of fruit after root-pruning or lifting than any other tree. Once, in filling a new house with trees, which was not finished till the end of March, we plauted some young trees when they were coming into flower, and they each bore a few fruit the same year. Last winter, about Christmas time, we also lifted and replanted a Victoria Nectarine that was planted in 1866 and had not been disturbed since, and it bore some dozen fruit during the past summer, and none of them were small.
J. S. W.

RIPENING THE WOOD OF VINES.

FIRM, short-jointed, well-ripened wood is essential to fruitfulness, and to the production of handsome, compact bunches of Grapes. Loose, straggling bunches generally denote unripe wood. There are several causes that have an influence upon the proper maturation of the wood in fruit trees, especially Vines. A heavy, retentive, over-rich border is often a cause of immature wood, and Vine-borders, from frequent top-dressing with rich manures, have a tendency to become over-rich, especially if the drainage is not perfect. This encourages the production of gross immature wood, late growth, and, consequently, loose straggling bunches, often followed by shanking. However a Vine border may be made, and whatever may be its depth of soil, or the materials of which it may be composed—and there is room for some difference of opinion on some of these matters—there is no question about the necessity for perfect drainage. Of course some soils are naturally dry, and therefore in such cases one does not require to plant on a heap of stones. In a case of this kind a drain along the front of the border and a little below its foundation, whether it be concrete or some other substance, will, for borders not more than 10 ft. or 12 ft. wide, be sufficient. For borders beyond that width, cross drains at right angles 6 ft. or 8 ft. apart should be laid in connection with the drain in front. If Vines are making gross wood that will not ripen through some defect in the border, half measures are seldom satisfactory. It is far better to clear the border out, saving as many of the main roots as possible; pack them away carefully in straw and mats to keep them from drying so much; then have the bottom properly laid, so that all surplus water will pass rapidly away.

In making new Vine borders, they should never be made all at once, no matter how wide the border may be. A healthy Vine will generally push its leading roots through it in one season, and if the border has no retaining wall in front, the roots will be through and outside the prepared border long before it is half occupied. It is better to fill in about a third of the border the first year, building up the front with turves nearly perpendicularly. In the case of old Vines that have been lifted, if the remainder of the border space is filled with tree leaves, say about March, the roots will feel an impetus that will be productive of marvellous results even the first year; and if the same treatment is continued, adding a little to the border annually, keeping the roots well at home, there will be little fear of unripe wood from root derangement. Leaves alone should be used—Oak or Beech are the best. There should be no admixture of stable manure; the latter heats violently and then cools rapidly, but a good body of leaves gives a gentle lasting warmth. A covering of the same material should also be laid on the top of the border to the depth of 1 ft. or so. At the end of the season the decaying leaves should be removed; the Vine roots will no doubt have penetrated the heap in all directions, but these may be cut back with impunity, and the loss of one root in this case will be the gain of a dozen or more. Making the border

in this way fills the whole of it full of roots, and one knows where they are; and if at any time the Vines require a little extra food, one knows where to apply it.

Thus much about border making, because unripe wood is often caused by deficient or late root action, from the borders being in a bad state, so that when this is the case the remedy may be applied in the right place. But there are, however, other causes to which the imperfect ripening of the wood may be fairly ascribed, especially with late Vineries. People often deceive themselves with the thought that, because the house has had abundance of ventilation, the wood must as a matter of course be well ripened; but this is not always so, as everything depends upon the air's temperature. A brisk circulation of warm, dry air furnishes just the required condition for hardening and consolidating the tissues of the wood and buds, and so rendering them fertile; but the same result will not be obtained if the air be at a low temperature. It is warmth that is required; hence the importance of lighting and maintaining a brisk fire occasionally at this season, or even regularly for two or three weeks if there be reason to think the wood is not sufficiently matured. And this applies not only to late Vineries, but also to mid-season houses, or such as ripen their fruit in July and August. These latter will in most cases now be clear of fruit, and a few days' brisk firing will help to finish off the wood and prepare it for pruning. All surplus growths should be at once removed, and the fruiting rods and spurs shortened back half-way to the base. This will admit a flood of light, which, in connection with a brisk temperature, will do much to complete the ripening process, and prepare them for the final pruning; and the sooner this latter operation is performed the better, after the wood is ripe. The same remarks, so far as thinning and shortening back the wood goes, apply with equal force to Vines on walls in the open air. All superfluous shoots should be at once removed or shortened back, to let in all that can be obtained of the sun's remaining power among the branches. What heat the wall absorbs is not lost, but is given off again; and this concentration of a higher temperature round the buds will materially help next year's prospects as regards the number and size of the clusters of fruit. C.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

The Crittenden Damson.—This is a variety of the Damson Plum that is not yet largely grown or widely known, but it is one that should be found in more or less quantities in every garden. I have trees here planted only two years since, and then only two years old, that are producing a good sprinkling of fruit. This early prolificacy is the distinguishing characteristic of this Damson. The trees have a somewhat pendent habit of growth; the wood is short-jointed, and fruit-spurs are produced in great abundance. The fruit is about the size of the old Damson, and of capital quality. It is a sort to be grown in large quantity for market use, and without doubt it will soon become popular.—A. D. [This variety is largely grown in the neighbourhood of Maidstone.]

The Lawton Blackberry.—Blackberries as a rule are not included in the list of garden fruits, though some of the finest-fruited varieties are certainly worthy of attention, and of these the Lawton is not only useful for culinary purposes, but also forms a desirable adjunct to the dessert, for which its large size, handsome appearance, and rich flavour recommend it. Ripening at the time when most of the kinds of Raspberry are over is another point in its favour. We lately saw the Lawton variety in Messrs. Lee & Son's nursery, bearing an abundant crop in various stages of ripeness. The appearance of the fruit at once suggested its adaptability for general culture. It is also known as the New Rochelle kind. Other good sorts are the Kittatinny, which ripens its fruit earlier than the last; and the Dorchester, a prolific and fine sort, which is in perfection in August, and continues in use for some weeks.—W. G.

Apple Orchards.—It will gratify those who have had misgivings as to sufficient quantities of Apples being planted at the present day to take the place of the orchards that must inevitably wear out, and which, even in the best Apple-growing districts, are notorious for the very large proportion which they contain of indifferent or all but worthless varieties, to learn that of late years there has been a considerable increase in the demand for young trees. In the Cheshunt Nurseries some 3000 standards used to be the number annually prepared for sale; now 14,000 are required. And another healthy sign connected with the subject is that one-half this number are confined to seven sorts, viz., Ribston Pippin, Cox's Orange Pippin, King of the Pippins, Blenheim Orange, Cellini, Keswick Codlin, and Lord Suffield, of which latter 1500 are each season wanted.—P. G.

THE FLOWER GARDEN.

ANNUALS AND THEIR CULTURE.

THE importance of a careful preparation of the soil previous to sowing seeds of annuals in the open ground cannot be over-estimated. This fact would, however, appear to be often lost sight of, and many who would be most particular as to the quality and condition of the soil when sowing under glass do not always deem it necessary to extend this care to open-air culture, and seeds are often consigned to the earth in such a manner as to preclude the possibility of their ever making satisfactory progress. The soil of a seed bed should be made as light and friable and sweet as if it were intended to be used for potting purposes. The mechanical character of soil varies; in some localities it is so light and sandy that a few days' fine weather suffices to bring it into the desired condition. Strong adhesive and clayey loams, however, require a considerable amount of preparation to render them sweet and mellow, and this preparation should be commenced early in the season. Where it is intended to sow annuals the places should be marked out, and the soil should then be turned up roughly by the beginning of March, then to lie until a period of dry weather has blown the sourness out of it, when it may after a shower be thoroughly stirred, and the lumps broken. If the work has been well carried out, there will be at least 9 in. of finely-pulverised, free soil, which may again be turned over with a fork, mixing with it some light sandy soil, such as the knockings-out of pots, or some wood ashes or burnt earth, and a little thoroughly decomposed manure. In such a prepared body of soil annuals of all kinds will thrive amazingly. The labour may appear excessive; but the reward will be great. Annuals often fail to develop their decorative capacity for the want of some such previous preparation of the soil, which, if more generally carried out, would render them even more popular than they are now. It is surprising to witness the luxuriant manner in which such things as Mignonette, Phlox, Linums, &c., grow, and the quantity of highly developed flowers which they produce when a good free root run has been provided for them. Sweet Peas, Convolvulus, &c., if they are to give a faithful idea of their value, must be supplied with plenty of good food, and in the form best adapted to the wants; in fact, no annual can give satisfaction unless its requirements are studied and provided for from the time the seed is sown, or the young plant set in the ground. Merely digging over the beds and borders and raking all smooth does not suffice; a stunted growth is too often the result of such a practice. It must be remembered that a few patches of well-grown annuals will reflect more lustre on a garden, and will afford much more satisfaction, than a whole establishment full of imperfectly developed specimens.

I do not think that annuals are so much employed as they might be, probably on account of a certain amount of difficulty which many experience in inducing the seed to germinate freely. A little practice would soon remedy this drawback. All have not the convenience for housing, or the means of purchasing, a sufficiency of bedding plants to fill their gardens; and really annuals are so varied, both in form and colour, comprising tints of the most vivid as well as the most tender and delicate hues, that they would alone suffice to render a garden gay and interesting the whole spring, summer, and autumn through. What can be more enlivening than a bed of blue Nemophila or red Silene in early spring? and what is more gorgeous and dazzling than masses of Asters and Zinnias? or again where can we find more chaste and refined hues than the Phloxes and Stocks exhibit? I have a vivid recollection of some beds of annuals grown in pots, exhibited by Messrs. Vilmorin at the Paris Exhibition of 1867. These beds were renewed every fortnight and formed one of the most interesting and most admired features in the horticultural section. I more especially remember a bed of Rhodanthe Manglesi, which was so striking and novel as to excite the admiration of all who saw it, and many who passed with comparative indifference choice varieties of Geraniums, &c., eagerly desired information concerning the culture of this pretty annual. A one-light frame, in a mild hotbed, will suffice to raise Asters, Phloxes, and all kinds of half-hardy annuals in abundance, enough to effectually embellish a good sized garden. Annuals have this advantage over bedding plants, they do not all come into bloom at about the same time—there is continually something fresh in process of development—each day brings something new with it. I would advise those who have not much storage room for bedding plants to go in largely for annuals. I have seen a garden of considerable dimensions where but few of the so-called bedding plants were used, but which was as brilliant and as interesting as one could well wish it to be. Although the body of soil in which the plants are to grow cannot well be made too pliable and porous, the surface should be pressed firm when the seed is sown. Many failures occur through leaving the surface soil so loose that the seed either becomes too deeply buried or

gets parched when germinating. For sowing hardy annuals, a fine day should be chosen, when the soil works easily and has become kind and mellow. It should be raked smooth and fine, clearing away lumps and stones, and should then be pressed firmly down where the seed is to be sown. Either drills or circles may then be drawn with a blunt stick to the desired depth, which for small seeds should not exceed $\frac{1}{2}$ in. Cover in the seed with fine mould, which must be made firm, and it will lie there securely until the first period of showery, genial weather brings it up. Seed merchants are often made to suffer for the unskilfulness or want of care and patience of the grower. When flower seeds are obtained from respectable firms, there should be but few failures in germination, and there would not be many if a few simple rules were laid down and carried out.

Another reason why annuals do not so often give the satisfaction they should do is that few have the courage to thin them out properly. It requires some resolution to take away five plants out of every six, and yet, when the seed has been thickly sown, a larger proportion than this must be sacrificed if the true character of the plant is to be realised. Growers should remember that the rules which guide us in planting bedding plants apply equally to annuals. Each plant must have a certain amount of space accorded for its development, without which the usual evil effects of crowding are soon apparent, and what would otherwise have matured into a beautiful mass of flower, degenerates into a weedy tangle, in which no one plant assumes the character which Nature has endowed it with. The better the soil has been made, the fewer plants need to be left together when sown in patches. Three plants will generally be found sufficient. Each individual plant then gets room to display its beauty. When massed, as it is, in beds on the lawn, then the thinning will have to be regulated by the manner of growth and natural régime of the plant, free growing spreading kinds generally requiring more space than those which are distinguished by a more upright habit. Zinnias, Stocks, Asters, and other half-hardy annuals, need to be sown on a slight hotbed, or in gentle warmth in a greenhouse. When fairly up they should be pricked off into pans or boxes, and when well established they should be removed either to a cold frame or to some sheltered situation. They should in any case be well inured to the atmosphere and be dipped in Tobacco water or fumigated before being placed in the open ground. By choosing warm, showery weather and planting firmly, they will speedily grasp the soil, and will experience scarcely any check; that is provided the roots are preserved intact, and are not allowed to dry. They should be watched for a time, and should be supplied with water if they show signs of needing it, and they will soon become well established. Such bushy ample-growing subjects as Zinnias should be allowed a considerable amount of space. They then become highly ornamental, and are very effective when dotted amongst shrubs, the most sombre hues of which serve to display their brilliant tints. In establishments where annuals are grown largely for seed, a generous well stirred soil and ample space between the plants are relied on to ensure a hearty vigorous development. The same system must be adopted by the private grower if he wishes to derive real pleasure from this charmingly varied race of plants. They resent neglect and injudicious treatment, but lavishly repay care and generous culture.

J. CORNHILL.

AUTUMN FLOWERS IN CHURCHYARDS.

WHENEVER I visit a strange town or village I always like to look round the churchyards, and, if time and circumstances permit, the churches also. Apart from the solemn thoughts suggested by the grey, timeworn walls, dating back, in many instances, for centuries, there is often something to be learnt of a useful, practical nature by those whose minds are ever open to receive impressions. In these days there is more outward reverence paid to the last resting-places of the dead than was formerly the case. Some years ago "God's acre" in many parishes was the worst-kept place in the neighbourhood. I have in my mind's eye several churchyards where the Docks, Nettles, and other rank weeds almost enveloped the tombs. Now this is altered, and in many churchyards really creditable attempts at decoration with shrubs and flowers are met with. There is no doubt still much room for improvement both in the materials employed and also in the manner of arranging them. In many churchyards and cemeteries in small towns that I have visited the chief want seems to be some tasteful, guiding, directing mind. Every one decorates the place of his dead according to his own ideas, and too often a weedy, incongruous effect is produced. Sometimes shrubs are planted on the grave whose growth is out of all proportion to, and not in character with, the position. No doubt in large towns the public bodies under whose charge the cemeteries are placed impose some restrictions upon the size of the plants placed on the graves by the friends of the departed; but in small towns and

in rural districts a very wide latitude is permitted to individual effort. I think nothing should be allowed to be planted on graves of stronger growth than Roses; and the shrubs and trees should be grouped or planted in isolated positions by some one person who possesses knowledge of effective grouping and some acquaintance with the materials employed and their probable development. The graves should be planted mostly with dwarf-growing plants, with flowers of sober colours. There cannot be anything in worse taste than planting scarlet Pelargoniums or other glaring common plants, such as are used in bedding arrangements. White or neutral colours seem most appropriate. The irregular groups of Lavender I saw in a churchyard the other day looked cheerful and sweet; so also were a patch or two of the single annual Larkspur in two or three colours mixed. The autumn-flowering Anemones I have seen most effectively grouped in churchyards, especially the white form *alba*, or as it is sometimes called *Honorine Jobert*. These were growing in irregular groups out of the Grass without any bare earth to be seen. The old China Rose is an especial favourite of mine for such work, and the old white Provence is a fit companion. The newer forms of Roses somehow I do not care to meet with in churchyards, especially when reared up on the end of long bare sticks; but the grandest of all plants for forming a group is *Bocconia cordata*. Five plants arranged in a group about $2\frac{1}{2}$ ft. apart would be a most attractive feature. How beautiful the plant is flowering this season! Some specimens I have lately seen have been at least 9 ft. high, each throwing up five or six—in some instances more—spikes of elegant flowers. The abundant rainfall seems to have increased the vigour of most hardy plants immensely, whilst the low temperature has dwarfed and stunted the more delicate sub-tropical and carpeting plants. I have already heard from more than one quarter notes of dissatisfaction concerning the bedded-out plants this season. Another rainy year will banish the Pelargoniums and such like plants from a good many gardens. Yuccas are excellent grouping plants for churchyards, and where several are planted, including *Y. recurva* and *Y. filamentosa*, there will seldom be an autumn without flowers. The Veronicas are another family especially suited for the work, and the taller forms of *Campanula* also, such as *C. persicifolia alba* and *C. pyramidalis*; whilst the *Tritomas* should not be omitted, as for striking effect they have no superiors, and the foliage is graceful and pleasing when the plants are not in flower. I have often asked myself and others the question when walking round churchyards and cemeteries—why the trees and shrubs should be altogether of such a sombre hue. The thought of death and decay will always be associated with feelings of sadness; but the decay of autumn and winter is followed by a rejuvenated spring, and the gloom of the churchyard might be, I think, brightened up by a moderate use of such plants as variegated Hollies and Maples. The warm glow of the former when in fruit would tend to make cheerful the home of the dead. The Yew and the Cypress may still be planted, but not as at present to exclude others of a more cheerful tone. Among *Coniferae* there is no plant so suitable as *Cupressus Lawsoniana* and its numerous varieties, all of which should be included, and the golden-tinted forms will tend to illuminate those of more sombre hues. The *Ailantus glandulosa* (Tree of Heaven) is a low tree or shrub especially suited for a group; its large elegant foliage will produce a new element in churchyard decoration, contrasting well with the materials commonly used now, whilst some of the variegated Ivies might be used to give variety to the walls, and more use might be made of the various forms of *Clematis* wherever vacancies occur on walls or buildings. Among shrubs at this season there is scarcely anything so beautiful as the Venetian Sumach, or Burning Bush as it is sometimes called, from its large singularly elegant clusters of red flowers; a good-sized bush of it would be a most attractive object, either isolated on Grass or in front of taller plants in a group. But one might go on singling suitable subjects out in this way until it became wearisome.

E. HOBDAV.

Eucharidium Breweri.—This elegant new annual promises to turn out a valuable acquisition, being of a more robust habit and having red flowers of a deeper, richer colour than those of *E. grandiflorum*. It may be seen, from the accompanying figure of a flower-bearing branch of the natural size, that the petals are curiously three-lobed, the central lobe being longer and narrower than the others. The filaments of the stamens are likewise very singular, being thick and club-shaped similar to those of some *Yuccas*. Like the other species of the genus it is a native of California, where it was discovered by Mr. Brewer on the dry summit of Mount Oso, Stanislaus county. Mr. W. Thompson, of Ipswich, imported seed of it; and he has succeeded in raising some plants, from one of which our drawing was prepared; but he despairs of saving much, if any, seed this unfavourable season. It is to be hoped that he will be more fortunate than he anticipates.—W. B. HEMSLEY.

AURICULA GOSSIP.

THOSE two green edges of ancient renown and modern celebrity, Page's Champion and Booth's Freedom, are certainly less easy to succeed with than most Auriculas. However, some growers are still unwillingly relieved of all cultural anxiety about them through not being able to get the plants; and before they can be plentiful again, they will have been superseded by seedlings in their own class decidedly superior to them. As to their habits, Champion is refractory in an unfavourable locality, such as a low situation, with its damps of earth and air, or a smoky atmosphere which, in and near such towns as Manchester and Sheffield, contains more that is deadly to plant life than the visible sootiness which intercepts the view and makes one's countenance ridiculous by sly touches on telling places. Freedom, when once well away, is a fine grower, but is often very tedious in the offset state, tempting the eager grower of one lingering little bit to call this sort unmanageable. Though both varieties have rich foliage when in health and active growth, yet it is susceptible of injury, and when the plants are at rest in summer or winter it is easily damaged by wet. Herein largely lies the secret of their delicacy. Upon Champion the effect of a damp situation and confinement when wet is to rot the outer foliage while green, causing a loss of leaf power that throws the plant into a decline. With Freedom under like circumstances the grass will wither round the edges, and being in summer-time naturally flecked with a yellow-green (a peculiarity common to several other varieties), a superabundance of damp about it is liable to lay hold of the quiescent foliage and injure it when in this character. Freedom's foliage is strongly ribbed on at the stem, and the collar of the plant is dangerously reduced when leaves are lost prematurely. I do not allow these varieties to receive any wet overhead, and am careful to have all plants of them so arranged in the frames or house that they cannot reasonably escape close attention. Beyond this I am not conscious that they get different treatment from the rest. They enjoy the same periodic change of quarters, they receive the same compost, and they are re-potted at the same early time (May) as all

the others. Perhaps if I come across a particularly choice morsel in the new compost heap, I should inwardly say, "Keep that for Champion," or "Give that to Freedom." But, as a broad rule, I find that what suits one Auricula suits the rest; or rather, that if you grow the whole collection with the care required to nurture your tenderer sorts, your "level best" will be rewarded with the highest results possible to your circumstances. It is a vicious system of treatment that neglects one plant a little to

pet another rather more. Mr. Douglas is unfortunate in having such solid plants as Laneashire Hero and Lightbody in this cool season running up with bloom, but it is better they should do so in August than a month later. In August many a plant that blooms will have time to manage a good heart against the spring, but the chances lessen quickly as the autumn passes on, and Hero and Lightbody, from their solid and stiff habit, are very likely sorts to be thrown out of time and time by autumn blooms. It is not a safe thing in this respect to have a collection of Auriculas flushed and active just as August ends. They should be encouraged to root rather to make lusty Grass and fat hearts so early. If they are securely-rooted the foliage and hearts are sure to follow in good time. Indeed hearting-up is one of the latest operations of the year, and really goes on all the winter. So far, my own plants are behaving well. Repotted early, as they always are, I have at present only less than 1 per cent. showing for bloom. These are Chas. Perry, Topsy, and True Briton, and a Colonel Taylor, all of them sorts given to this habit. I hope our friend at Brookhurst will reveal to us his observations on the late and early potted plants which he has, like Mr. Douglas, been experimenting with, and that Mr. Llewellyn will tell the interesting story of his own success with "Freedom."

Kirkby Malcarrd, Ripon.

FRANCIS D. HORNER.

Eucharidium Breweri.

Primula grandis.—Dr. Regel, who has cultivated this plant for some years in the Botanic Garden, St. Petersburg, says that it is of botanical interest on account of the anomalous form of its flowers and the large size of its leaves, but that it possesses no floral value.—W. B. HEMSLEY.

FLOWER GARDENING IN VICTORIA PARK.

OF all the London parks this is the least favourably situated as regards purity of atmosphere, for, besides being surrounded by a densely populated neighbourhood, it is also under the baneful influence of the myriads of factories which incessantly pour forth from their chimneys volumes of poison-laden fumes. It is, therefore, a matter of surprise that vegetation under such circumstances thrives so well as it does. Some of the trees, indeed, and especially the Hollies, which abound in this park, will compare favourably, as regards size and symmetrical growth and vigour, with any to be met with elsewhere. The entire absence of Conifers, however, is a remarkable instance of a particular class of trees that cannot live in a polluted atmosphere. It is flowers, however, rather than trees to which the following remarks apply, and more particularly to the annual bedding display for which this park is justly celebrated.

Sub-tropical gardening is not practised here on such an extensive scale as it is in Battersea Park, though what has been done is very effective, and would have been much more so in a favourable season. The fine-foliaged annual plants, such as Wigandias, Solanums, Ricinuses, Grasses, Hemp, and similar plants, have not yet attained half their ordinary height; whilst in the case of the tender perennial kinds, such as Cannas, Aralias, Ficuses, Abutilons, Acacias, &c., their unthrifty appearance is even more striking. A bed, however, of the better kinds of Ferns, such as *F. conspicua*, *communis*, *Ferulago*, and others, affords a fine contrast to the ordinary state of matters, as since spring they have been highly attractive, perfectly regardless seemingly of the unpropitious weather to which they have been subjected. It is such plants as these, and there are hosts of them to be found, that should be planted more liberally in all gardens, as their bright and fresh appearance affords some compensation for the ill success which has attended the more tender plants. For example, what tender plants can surpass in beauty in the open air in this climate the noble *Gunnera scabra*, a plant which has leaf-stalks 6 ft. and 8 ft. long, supporting blades a yard across; also its congener *G. manicata*, which is of still nobler dimensions; or *Bocconia cordata*, *B. japonica*, *Polygonum sachalinense* and *cuspidatum*, the Pandanoid *Eryngiums*, *Acanthuses*, Cow Parsnips, Sunflowers, *Onopordons*, even the many kinds of Rhubarb, and various others, besides the many handsome varieties of hardy Grasses, Bamboos, &c., which we have at our service. By a judicious selection and arrangement of such materials as these, we might in time dispense with tender, fine-leaved plants. An incentive would thus be given to the introduction of new plants suitable for such a purpose. The plants used in sub-tropical bedding here are much the same as those employed in former years. One novel feature, however, is a bed of the single-flowered Dahlias, which excited so much admiration at various places last year; the kinds are *D. coccinea*, *Cervantesi*, and *Paragon*; when in flower these will be highly attractive. The old *Amicia Zygoneris* is used here with good effect, and it succeeds tolerably well. The Coral plant (*Erythrina Crista-galli*) presents a showy appearance when planted in such masses as may be seen here. The Chilean Beet, too, a plant not used so extensively as its decorative merits entitle it to be, is employed here in combination with other plants in the form of belts, a purpose for which it is admirably adapted. Mignonette and other sweet-scented plants here and there also form commendable features, which seem to be much appreciated.

The exceptionally wet season which we have had has here, as elsewhere, greatly impaired the beauty of the bedding arrangements. Most of the plants, such as Pelargoniums, have outgrown their prescribed limits, but the absence of flowers is very conspicuous, though none but well-tried kinds are grown, a desirable plan where such a vast number are annually required, and where failure would produce much inconvenience. The season, too, has been a most adverse one for all kinds of succulent plants, which, in some instances, are quite rotten. They are used extensively in this park, and with remarkably fine effect when favoured with warm and dry seasons.

The carpet beds are much more successful than those in which flowering plants are used; indeed, some of the designs look better than we have hitherto seen them. Here may be seen scrolls, triangles, hearts, shields, and circles of various sizes, filled with a great variety of plants, arranged in intricate patterns. All the beds are characterised by a delicate finish, and a bright fresh appearance. The group of beds which occupy a semi-circular lawn near the centre of the park are remarkable for their dazzling brilliancy, the majority consisting of fine-leaved plants. The rich green *Mentha Pulegium gibraltarica* is found to be one of the best plants for using for the groundwork of the patterns; the pretty *Sedum glaucum* is also a capital plant for similar positions. As before remarked the tender plants such as the various kinds of *Alternanthera*, *Coleus*, &c., have not grown satisfactorily this year, though even in their present state they make an effective combination intermixed with other plants. The scroll-work near one of the eastern entrances is very

elaborate, and is much admired, as there are but few failures, and all the plants used have filled the pattern well. W. G.

ORNAMENTAL CLIMBERS.

MR. W. C. BARRY, of the Mount Hope Nurseries, has furnished the *Rochester Democrat* with a list of ornamental climbers for the embellishment of the house and its surroundings. Mr. Barry names first the Virginian Creeper, or American Ivy (*Ampelopsis*) as the most valuable climber, all things considered, being hardy, growing very rapidly, and having rich green foliage that changes to brilliant crimson-scarlet in autumn. It is especially suited to covering walls, trunks of trees, and verandahs. *Ampelopsis Veitchi* is newly introduced, comparatively speaking, from Japan. Its leaves, which are small, over-lap and form a dense sheet of pleasing green. It is slightly tender when young, but afterwards becomes quite hardy. It adheres to walls without fastening. Its fine green colour changes to crimson-scarlet in the autumn. *Aristolochia* is a fine climber, with broad, heart-shaped leaves, and is a twiner, requiring a support. Among Honeysuckles are the well-known fragrant Woodbine. Hall's Japan Honeysuckle bears white and yellow flowers from June to November, is a partial evergreen, and is regarded by Mr. Barry as the best Honeysuckle we have, and one of the most valuable in the entire collection. The Monthly Fragrant Honeysuckle has red and yellow flowers; the Scarlet Trumpet has bright scarlet, tubular flowers; and the Japan Golden-leaved has variegated or netted foliage, the last in bright summers being very showy. The Bignonia or Trumpet Flower is well known for its large, trumpet-shaped, crimson flowers, which are produced in August. It is invaluable for covering stumps, trees, &c. Varieties give different shades of scarlet and crimson. *Akebia quinata*, introduced some years ago, is light and graceful in growth, has sweet-scented flowers, and is hardy. *Periploca* is a hardy and vigorous twiner, with glossy leaves, and is quite hardy. Under the head of Clematis Mr. Barry remarks: "Within the last ten years hardy Clematises have been wonderfully improved, and the newer sorts now in cultivation are justly regarded as the most beautiful and striking ornaments known for garden decoration. Contrary to the general impression, the severest winters do not injure them when slightly protected with straw or leaves. In order to induce a long succession of bloom, liberal culture is absolutely necessary, and a deep, well-drained soil, consisting of loam, rotten manure, and leaf-mould, is the most suitable in which to plant them. During warm, dry weather in summer, liquid manure may be given them advantageously, and every year the surface of the ground around them should be mulched with manure to keep up their strength. Clematises are gross feeders, and must be fed well to flower freely. They may be used in many ways, either trained on verandahs, walls, or trellis work; or they make superb single specimens on the lawn, trained to some ornamental support. They may also be employed as permanent bedding plants, and pegged down like the Verbena; or with a wire support of neat design raised about 1 ft. from the ground to run on, very pretty beds may be formed. On trees and arbours their showy and handsome flowers are very effective. Some of the choicest varieties are as follows: Jackmanni, violet-purple; Miss Bateman, pure white, and somewhat fragrant; Lady Londesborough, of a silvery-grey colour, with a paler bar on each sepal; velutina purpurea, blackish Mulberry-purple, the deepest coloured of all the varieties of this type; Viticella venosa, reddish-purple, veined with crimson; Lady Stratford de Redcliffe, a new variety of a delicate mauve colour, with the anthers chocolate-red; Otto Fræbel, one of the largest, finest varieties yet obtained—flowers greyish-white, or French white, and of a thick, fleshy texture; Marie Lefebvre, pale silvery-mauve, with a deep mauve-coloured bar. Mr. Barry regards the Chinese Wistaria as unquestionably the most elegant wall plant we have. In the city of New York it is employed extensively for decorating the fronts of dwellings, and has a fine appearance when climbing over evergreens. Its long, pendulous clusters of pale, blue flowers have an admirable effect. There is a white variety, and one with double blossoms.

Ellacombe's Yucca.—I do not think it quite fair that my name should be honoured with this plant. About fifty years ago, when I was hunting for Yuccas in the London nurseries, I saw this plant at Loddiges's; it was not named, but in his dry, humorous way, Mr. Loddiges said, "If you will buy it and pay for it you may call it what you like." I took it to Bitton, where it thrived luxuriantly, and afterwards I gave a plant to my friend Mr. Osborn, of the Fulham Nurseries, who attached my name to it. In a letter long after my purchase, Mr. Loddiges informed me that he raised the plant from seeds sent from Malta in 1817. It was named by Haworth tenuifolia, and is described in his "Suppl. Plant. Succul."—H. T. ELLACOMBE, *Rectory, Clyst St. George, Devon.*

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Allium pulchellum is now very pretty in Mr. Elwes's garden. It was obtained from Bitton, and is superior to most herbaceous plants that flower at this season. In colour it is a showy rose. It is a plant of great value for the mixed border.—V.

The Bog Bean (*Menyanthes trifoliata*).—This is certainly one of the prettiest of our native plants, and one which is often met with in watery, boggy places, although it is not always found to be in flower, but when it is it is well worth making an effort to obtain. It is a hardy plant, and I have met with it in abundance in wet boggy pastures. Cattle do not apparently disturb it, doubtless on account of its bitter taste, it being used in some cases as a substitute for Hops.—AN OLD GARDENER.

Streptopus amplexifolius.—This interesting and graceful plant is now laden with its crimson-red and large oval berries in Mr. Elwes's collection. It would succeed in association with peat and shade-loving plants among American shrubs. It resembles in habit a Solomon's Seal, and will find a place in collections of curious plants.—V.

The Edelweiss at Bayfordbury.—I send you a sketch of a single blossom of Edelweiss. The plant was procured at Davos-Platz in Switzerland last year, and placed by Mr. Baker on one of the lower ledges of his new rock-garden lately arranged at Bayfordbury. The sketch is exact in size. I have found many large specimens on the Alps, but I have never found or seen one to approach this.—S. M. [The sketch in question measured 4 in. one way and 3 in. the other.]

Effect of Wet on Succulents.—I notice a complaint in THE GARDEN that the wet summer has injured Succulents in the Alpine garden. My pigmy rockery or Japanese garden was never so flourishing as it has been this season. Although we are on the clay, none of the little Succulents turned out this summer (including some rare ones) have suffered; but this is not all. I last year obtained from Messrs. Backhouse a plant, 3 in. high, of *Agave utahensis*. It has stood the winter and is plump and rigid. In appearance it is similar to the great American Aloe; I am glad to say it has not increased much in size. I sprinkle gravel on the surface of the rockery, which gives it a finished appearance, and I believe is beneficial.—C. E. ISHAM, Lamport Hall, Northampton.

A Garden of Hardy Ferns.—When particular attention is directed to the cultivation of a favourite class of plants the result generally is that the collection attains a degree of perfection seldom acquired in an ordinary way. Such is the case in the garden of Mr. P. H. Rooke, Weybridge Common, which is almost entirely devoted to the culture of hardy Ferns of all kinds, and it need scarcely be mentioned that they are represented by specimens of a size rarely met with. The collection is for the most part planted on rockeries, but in studying the peculiar likings of certain kinds, every available position and mode of treatment is considered. The huge plants of the larger growing kinds have places specially prepared for them, in which they can display their beauty to the best advantage. The almost endless varieties of *Athyrium*, *Lastrea*, &c. are numerous represented, as well as the rarer of the British kinds, and the majority of the hardy exotic species; amongst which the elegant North American Maidenhair (*Adiantum pedatum*) is noteworthy, on account of its large size and unusual vigour.—W. G.

***Euonymus radicans variegatus* as a Permanent Edging**.—No plants can surpass and few will be found to equal this dwarf species of the Spindle tree for forming permanent edgings to flower beds. A great portion of the beds devoted to summer flowering plants in the immediate vicinity of the mansion at St. George's Hill, Byfleet, are edged with it, and the effect at the present time is of the most pleasing description. There is one detail in the arrangement to which I would wish to direct attention, and that is the beds are all raised considerably above the ground level; the *Euonymus* consequently forms miniature walls of variegation around them, and serves in no small degree to heighten the effect of the flowering plants contained in them. Mr. Rose intends to employ this plant on a still larger scale, and it must be admitted that the effect realised by its use fully justifies the favour in which he holds it. Not only does this *Euonymus* harmonise well with any kind of flowering plants with which it may be associated, but it differs from the golden variegated kinds in not being in the least susceptible to injury from severe frosts, showing up charmingly fresh and bright against the green turf during the dull, sunless winter months. The flower beds at St. George's Hill are by no means in very sheltered situations, but I am informed that the beauty of the edging was not in the least degree marred by the past exceptionally hard winter. I would strongly advise those who may wish for a neat, always fresh, cheerful, and easily-managed permanent bordering to give this plant

a trial. It succeeds in almost any kind of soil, thriving admirably even when it is of a poor sandy nature.—J. C., Byfleet.

Sedum Ewersi.—This Stonecrop, a very pretty one, is blooming profusely at this season. It is a good rock plant, and also snitable for small vases, the flowers being a rosy lilac. It is quite as good a plant as Siebold's Stonecrop, though not nearly so common.—V.

Cyananthus lobatus.—This is so often seen in a weakly condition that few know its value. A tuft of it on rockwork in Mr. Elwes's garden is now quite showy with blue-purple flowers, which are as freely produced as those of a *Campanula*. It is an excellent rock plant, and should be placed in a fully exposed position.—R.

***Polygonatum cuspidatum compactum* on the Grass**.—As seen growing in Mr. Stevens's garden at Byfleet, this plant presents a very attractive appearance. It is there employed as a "dot" plant, for which purpose its manner of growth well qualifies it. The flowers, though neither large nor showy, are produced in great profusion, and apparently possess the ability of resisting without injury a large amount of unseasonable weather. This *Polygonatum* appears to luxuriate in a sheltered but sunny situation, and altogether should decidedly find a place in gardens where variety is desired.—J. C.

Anemone vitifolia.—This plant is now in flower in Mr. Elwes's collection at Cirencester, and is very interesting in comparison with *Anemone japonica* Honorable Jobert. The name *A. vitifolia* occurs in many catalogues and on labels, but we have not before seen any plant under the name that differs from what is known as *A. japonica* or one of its forms. Mr. Elwes's plant has the leaves simple and Vine-like, as the name implies, whereas the white *japonica* has the leaves compound with the exception of a few root leaves. *A. vitifolia* is earlier in flower, and the blossoms not quite so large, the white having a slight tinge of pale purple outside. Mr. Elwes considers the white *Anemone* really the normal form, and the reddish one the sport. Considering the character of the species that come nearest to it, and also the malformation usual in the red form, this seems the right view—nothing more natural than that from the white kind the red form should sport. *A. vitifolia* was in cultivation before Mr. Gordon raised a number of hybrids between it and *A. japonica*.—V.

Gladioli at South Kensington.—One of the finest collections of Gladioli that have yet been shown was exhibited the other day at South Kensington. It need scarcely be stated that it came from Messrs. Kelway, of Langport, the leading raisers and cultivators in this country of this the most beautiful of all autumn flowers. The examples shown were in every point superb, and exhibited remarkable diversity in colour, with large size and breadth of petals—points essential in a good Gladiolus flower. For more than a quarter of a century attention has been directed at this nursery to the improvement of this popular bulbous plant, and the collection is now very extensive, no fewer than 15 acres being devoted entirely to Gladioli alone, and over 200,000 seedlings are annually raised. During the flowering season as many as 2000 blooms may be cut weekly. This is ample proof that skilful culture, and the advantages of a Somersetshire climate, suit the requirements of the Gladiolus admirably. Mr. Kelway also informs us that he plants them in various positions, on high ground as well as in low-lying places; and states also that there is considerable diversity in the nature and quality of his soil, some of it being of an adhesive character, whilst in other parts sand and gravel predominate. A judicious application of manure is highly conducive to their successful treatment.—G.

Hardy Plants at Byfleet.—The following plants now in flower in Mr. Stevens's garden at Byfleet are well worth attention. *Campanula grandiflora* is a very meritorious kind; the flowers are large, of good substance, and the general growth of the plant is robust and fairly compact; altogether it may be considered as a very desirable variety. *Euphthalmum cordifolium* is, though rather coarse, yet a very showy and effective plant, and would be a suitable subject, as would also *Epilobium alpinum*, for dotting here and there amongst low-growing shrubs. Most plant growers are acquainted with the Cardinal Musk (*Mimulus cardinalis*); a variety of it now growing at Grasmere, named Orange Perfection, is in some respects an improvement upon the type, the flowers being larger and the habit more compact. The individual flowers of *Lychnis viscaria* fl.-pl. would also be found useful in floral arrangements, more especially in hand bouquets. They are very double, pure white, much resembling a *Gardenia* bloom, and are produced continuously for a long period. Mounted and surrounded with sprays of Maidenhair Fern, and sometimes scented *Geranium* leaves, they would produce a very good effect. *Echinops strictus* should also receive a word of commendation, the flowers exhibiting a rather peculiar shade of blue, and evidently sustaining without injury a considerable amount of tempestuous weather.—C.

NOTES OF THE WEEK.

New Anthurium (*A. scabriusculum*).—A fine new tropical Aroid bearing this name is now in flower in the Aroid House at Kew. In general appearance it somewhat resembles the better-known *A. zebrinum*, but is of larger growth. The leaves are much elongated, attaining from 1½ ft. to 2 ft., and have a heart-shaped base. The colour of the leaves is a rich bronzy-green, which has a bright polished appearance. The leaf-stalks are from 3 ft. to 4 ft. in length, but, unlike *A. zebrinum*, they are of a plain green hue, and lack the singular stripes which suggested the name of that species. The habit of the plant is bold yet elegant, and it will doubtless be a welcome acquisition. It is a native of Borneo, whence it was introduced by Messrs. Veitch & Sons, who presented the specimen under notice to the Kew collection.

Bomarea Carderi at Pendell Court.—By far the finest specimen with which we have yet met of this fine Amaryllid is growing in Sir G. Macleay's garden at Pendell Court, where it is planted out in the border of a cool and well-ventilated house devoted entirely to plants from temperate regions. Its slender twining stems are trained up a pillar to a distance of half their length and the upper parts are tied horizontally to the roof. Each stem is terminated by a huge umbel of flowers which hang vertically. From twelve to fifteen flower stalks about 1 ft. long radiate from the tip of the stem, each bearing three and often four blossoms, which in shape somewhat resemble those of *Lapageria* though not so large. The colour of the flowers is a rosy-pink with the tips of the petals copiously spotted with greenish-brown. This *Bomarea* comes to us from the cooler parts of the Colombian States in South America. In some collections it is known under its synonym *B. Jacquesiana*. It would be difficult to name a more desirable greenhouse climber than this, and its culture moreover is simple if at first it is placed under proper conditions as to growth.

A rare Aristolochia (*A. ringens*).—One of the most singular species of this interesting family is now in flower in Messrs. Veitch's nursery. As regards habit of growth it is in the way of *A. ornithocephala*, a kind often seen in stoves. The flowers, too, are somewhat of the same colour but different in shape. The inflated calyx is produced in a long tongue-like manner, and is covered on the upper surface with short dense hairs, which all point downwards, an arrangement, no doubt, to prevent the egress of insects which are attracted to the flower by the odour. The other projecting portion is so arranged as to represent the expanded jaws of an animal, which aptly suggests its specific name. To the lovers of the curious among plants this will doubtless be a source of much interest, and it may be as easily grown as its tropical congeners.

Cornus Mas elegantissima.—One of the most beautiful shrubs that have come under our notice for some time is this exquisite variety of the common Dogwood. It is of the same vigorous habit as the type, but it has a decidedly pendulous tendency. The leaves, which are as large as those of the ordinary Dogwood, have a broad margin of a golden hue encircling the bright green tint of the centre, which, during the greater part of the year, is suffused with a deep rosy colour, which renders it distinct from all other kinds, and highly attractive. For planting in mixed shrubberies, or as isolated specimens on lawns, it is admirably suited, as the surrounding green hues show off its fine variegation to advantage. We saw it a few days ago in Messrs. Lee & Sons' nursery at Isleworth, where it was raised. It is there grown in the form of low bushes, half standards, or grafted on high stems, so as to adapt it for planting in dense shrubberies.

Gunnera manicata.—The now well-known *G. scabra* is generally considered to be one of the handsomest foliaged plants that we have in cultivation that will survive our winters in the open air. It is, however, far surpassed in grandeur by its congener *G. manicata*, of which we saw some very fine examples in Sir G. Macleay's garden at Pendell Court, where it forms a highly attractive feature as isolated specimens on the lawn. It is very distinct from the commoner kind in the form of its leaves, which are more heart-shaped at the base, and also in the larger size they attain; in some seasons the leaves measure 4 ft. to 6 ft. across, with stalks of a proportionate length. It differs, moreover, in the manner in which the small, inconspicuous flowers are arranged on the stout, conical stem. In *G. manicata* the secondary spikes are short and stiff, and in the other they are slender and flexible. The same mode of culture is applicable to both kinds, as they both require to be planted in a deep, rich soil, with abundance of water during the growing season. At Pendell Court both species are growing in one mass planted near the margin of the lake, where the roots penetrate into a saturated subsoil. As isolated specimens on lawns, &c., there are certainly no grander objects attainable, and it ought to be grown more extensively, especially in our public parks and gardens.

Ardisia Oliveri.—This handsome stove shrub is now flowering in Messrs. Veitch's nursery. It is erect in habit and has rather large leaves which gracefully recurve. The flowers somewhat resemble in size and form those of an *Ixora*, but are of a pleasing rosy-pink colour. They are borne in large globular clusters terminating the branches. It is a native of Costa Rica, from whence it was introduced a few years ago by the late M. Endres.

Crassula alpestris.—This is one of the most interesting among the hardy succulent plants in flower on the rockeries at Kew. It is of a trailing habit, growing only from 1 in. to 3 in. high, and has bright red branches furnished with fleshy pointed leaves. Every branch is terminated by a cluster of white blossoms, which, being produced abundantly, give the plant a very pretty appearance, which lasts for a considerable time. It is yet rather scarce in gardens, but it makes a good rock plant.

Hypericum patulum.—This is one of the handsomest of all the St. John's Worts, as it possesses in addition to large size, rich colour, and abundance of flowers, a very elegant drooping habit which adds considerably to its beauty. It is grown extensively by Messrs. Lee & Sons, in whose nursery at Isleworth it now forms an attractive feature, both in the form of masses and as single specimens. Though a Japanese plant it is quite hardy here, and is a capital subject for mixing amongst choice border flowers. Unlike its well-known congener the Rose of Sharon (*H. calycinum*), it prefers an exposed and sunny position, and moderately stiff soil.

The Meadow Beauty (*Rhexia virginica*).—In but few places is this beautiful Melastomad to be met with in anything like a flourishing condition; but a bed of it in Messrs. Osborn & Son's nursery at Fulham is now very attractive, its rosy-pink blossoms being borne in great profusion. It is generally treated as a bog plant, but here it is growing in company with hardy Azaleas in a peaty soil. It was this bed which furnished the material for the coloured figure of it given in THE GARDEN, p. 294, vol. XI.

Montbretia Pottsi.—This is a graceful and bright-flowered (orange-scarlet) bulbous plant now in bloom in the open borders at Bitton, where it has proved to be quite hardy during the past two years. It grows and increases freely. In stature and colour it resembles at a little distance the old and well-known *Tritonia aurea*, but it is even a better plant.—V.

Yucca Ellacombei tortulosa.—We have received from Messrs. Osborn & Sons, Fulham, a splendid panicle of this fine hardy plant, which admirably exemplifies what a grand subject it is for garden decoration. This variety does not differ materially from the type, and the colour of the flowers is the same. *Y. gloriosa globosa* is another fine form, with the flowers of a more globular shape than in the ordinary kind.

Burbidgea nitida.—The height of this plant was erroneously stated in the note at p. 196 to be from 2 ft. to 10 ft. Mr. Burbidge informs us that 3 ft. is the maximum height which it attains, even in the most favourable localities in its native country, which is in the very wet, rich, and shaded forests of Borneo.

Amaryllis Acramanii.—This beautiful bulbous plant is now in fine flower in the College Botanic Garden, Dublin. It is planted deeply near the wall of one of the stoves, a position in which it has proved quite hardy, though often in winter covered with water. Its handsome, rich velvety flowers, combined with glossy brown-tinged leaves, render it highly attractive.—F. W. B.

Kniphofia triangularis.—Under this name there is a plant flowering in the Kew collection which much resembles the pretty *K. MacOwani*, now so much esteemed as a hardy border flower. Whether the plants are distinct or not we are unable at the moment to say; but if botanically distinct, the two are so much alike, that where one of them is grown the other will be unnecessary.

Goodyera pubescens.—This is very successfully grown in one of Messrs. Lee & Sons' nurseries in the open air planted in a peaty soil in a frame placed in a partially shaded position. The plants, which are numerous represented, are now in flower, and though their blossoms are by no means attractive they show that the conditions under which the plants are placed are such as they require. It is at all times of the year a source of much interest, as the beautiful silvery network of the leaves is the nearest approach amongst hardy plants to that of the *Anæctochili* of the tropical forests. As to its perfect hardiness there can be no doubt as it has for some years withstood the winter cold though quite unprotected.

Kelway's Conqueror Cucumber.—On September 1 a specimen of this variety was cut in the Kelly Gardens, Devonshire, 2 ft. 9½ in. long, 6½ lb. in weight, and 9 in. in circumference at the centre, which was not the widest part. The Cucumber was presented to the Duchess of Bedford, who pronounced it excellent. Some was eaten raw and the rest stewed.—REGINALD KELLY.

TREES, SHRUBS, AND WOODLANDS.

THE SHRUBBY SPIRÆAS WITH PINNATELY-DIVIDED LEAVES.

AMONGST hardy deciduous shrubs with ornamental flowers there are few more pleasing to the eye than the small group of Spiræas that have large pinnately-divided leaves and ample, terminal, plume-like panicles of white flowers similar to those of *Spiræa sorbifolia* represented in the accompanying engraving. This group comprises only four species, or, as some botanists regard them, varieties, all of which are natives of Asia, three of them inhabiting the north-eastern part of the Continent and some of the islands, and the fourth, *S. Lindleyana*, the Himalayan Mountains. In a recent monograph of the Spiræas and their allies M. Maximowicz has revived the generic name *Sorbaria* for this group, but for us they remain Spiræas still. The characters on which this genus, and the other genera which the author in question separates from the genus *Spiræa* (as generally understood), are based, are variations in the nature of the seed-vessels and seeds. Furthermore, the four species or varieties of this group, which we may call *Sorbaria*, are so closely allied that permanent differential characters exist only in the same organs. In aspect, however, they are very different, especially in stature. M. Maximowicz distinguishes them as follows:

1. *S. KIRILOWI*.—Style below the apex of the carpel before dehiscence.

2. *S. GRANDIFLORA*.—Style terminal; flowers small—about a fifth of an inch in diameter; leaflets very taper-pointed; flowers large, $\frac{1}{2}$ in. in diameter.

3. *S. LINDLEYANA*.—Carpel having a very prominent smooth keel down the back; hairs, when present, simple.

4. *S. SORBIFOLIA*.—Carpel with an indistinct hairy keel; hairs, when present, stellate.

The difference in the size of the flowers holds good only for the wild specimens, and probably not all of those. Thus *Lindleyana*, which is perhaps the finest of the group, has under cultivation even larger flowers than the dimensions given by Maximowicz for *S. grandiflora*. Under favourable conditions *S. Lindleyana* attains a height of 12 ft. or 15 ft., and sometimes it grows even higher. When the plant is young and vigorous the massive plumes of flowers are often 2 ft. or 3 ft. long, overhanging and intermingling with the beautiful dark green foliage, forming a magnificent sight. Like most other shrubs it can only develop its full beauty when standing free. In this way it naturally forms pyramidal or hemispherical clumps, always attractive when in leaf, and specially so at this season of the year when in full blossom. It also succeeds well treated as an herbaceous plant that is cut down every winter. The foliage and flowers are usually finer when the plant is thus treated. We have called these shrubs deciduous, although *S. Lindleyana*, for example, is almost evergreen, the old leaves in wild winters falling only a short period before fresh ones appear. *S. sorbifolia* has a wide range in Siberia and Japan, and varies very much in the degree of hairiness of its leaves from a dense tomentum to almost complete nakedness. Like *S. Lindleyana*, it is a tall-growing shrub, and it is even hardier;

but in spite of its having been introduced into British gardens as long ago as 1759, it is rarely planted. It seems to have succumbed to the prevailing system of crowding shrubs together in such a manner as to provide for the early death of the weaker kinds. Under such conditions these Spiræas cut a very poor figure, even in the early years of a shrubbery, as it is called; and if they do not actually die in the struggle for existence their miserable appearance dooms them to the rubbish heap. *S. grandiflora* syn. *S. Pallasi* and *S. sorbifolia* var. *alpina* differ very much, in the wild state at least, from the preceding, growing only about 1 ft. high, and having quite small, obtuse leaflets. The inflorescence, moreover, is short and few-flowered, and according to M. Maximowicz, the flowers expand in centrifugal order, from the top downwards, or in the reverse order to those of *S. sorbifolia*.

Nevertheless, it would seem that it is really nothing more than a northern race of the same species, the difference in stature being due to climate. Indeed M. Maximowicz states that a plant raised from seed, in the botanic garden of St. Petersburg, at first resembled the typical wild plant, but year by year it became more like *S. sorbifolia*, and it is now a branching shrub 4 ft. high, with large leaves and numerous flowers, the leaflets acute and in shape near those of *S. sorbifolia*. But, he adds, the size of the flowers and their centrifugal order of expanding remains the same, hence he hesitates to unite them. The only other species at present known is *S. Kirilowi*, of which we have seen dried specimens only. It was described from specimens cultivated in gardens at Peking and other places, and, although closely resembling *S. sorbifolia* and *S. Lindleyana*, it is readily distinguished by the characters given in the above key to the species. The leaves are quite hairless, and the plant forms a shrub 7 ft. to 12 ft. high. W. B. HEMSLEY.

[The specimen from which the annexed engraving was prepared came from Mr. Stevens's garden at Byfleet, which contains a fine collection of such plants.]

Spiræa sorbifolia.

The Athole Woods.—

The report of the recent excursion of the Scottish Arboricultural Society to these woods brings before the public many facts interesting to students of forestry. 1. At Little Dunkeld the Corsican Pine has far outstripped in growth the native Scotch Pine. 2. In the Ladywell nursery experiments are being made in rearing to a considerable size the *Picea Nordmannia* under the shelter of other trees. Hitherto considerable difficulty has been found in raising this tree in open situations, as when put out young it is liable to be killed down by frosts, and attacked by vermin. 3. Crops of Larch are not found to succeed well after previous crops of coniferous trees of any kind. 4. The bark of the Hemlock Spruce (*Abies canadensis*), a fine specimen of which was pointed out near the Hermitage Bridge, girthing 10 ft., with a height of 80 ft., is in America extensively used for tanning purposes. Its market price is about 15s. per ton, as against from £5 to £6 for Oak bark. The area of country producing this bark in America was stated to be over 10,000,000 acres. With an abundance of raw hides always available, this industry must very seriously affect the leather trade in our own country. 5. Some of the finest Scotch Pines were found growing upon a gravelly soil, which afforded them thorough drainage, and at

the age of 150 years they were seen to be still in good health, with clean bark, and covered with the lizard-like scales belonging to the indigenous Scotch Fir. 6. On the banks of the Tay, in an open glade, a fine specimen of the Silver Fir (*Picea pectinata*) was seen, which had attained a height of 112 ft., and measured 14 ft. 6 in. in circumference at 5 ft. from the ground, and at New House Bank a Larch was pointed out measuring 13 ft. 10 in. in circumference near the ground, and rising with a straight, clean, tapering stem to the height of 120 ft. This is supposed to be the finest specimen of *Larix europæa* in the country.—A. J. B.

WOODLAND LAWNS AND WOOD RIDES.

THE best time in the whole year for sowing Grass seeds, whether for the formation of lawns and meadows, for wood rides, or for recently-cleared and open spaces in woodlands, which are either to be mown or to furnish cover for game, is from about the last week in August to the middle of September. Later autumn sowings are, during mild winters, frequently attacked by slugs, so that spring patching becomes necessary; and during very wet or unusually severe winters some of the more tender Grasses perish before they get well established. The proper preparation of land for laying down is good and clean cultivation, a thorough pulverisation, a firm bottom, and a fine surface. A soil tolerably light and loamy, and also rich in vegetable matters, may be laid down to pasture without much trouble; but some of the clay soils, in consequence of the small quantities of vegetable matter contained in them, are with difficulty turned into pastures, though when once fairly established they exceed in value those upon lighter lands.

In selecting land for laying down, one of the first considerations should be thorough drainage, as without this the best kinds of Grasses will not establish themselves upon retentive soils. Wherever the Marsh Bent Grass (*Agrostis alba*), the Floating Meadow Grass (*Poa fluitans*), and the Reed Meadow Grass (*Poa aquatica*) flourish, there we may conclude that the soil contains too much moisture.

Before selecting seeds for any land the nature of the soil should be ascertained by careful observation, or if necessary by analysis. The three classes of light, medium, and heavy are those commonly accepted by seedsmen as the bases of their calculations in selecting suitable seeds, and by allowing a proper quantity for a medium soil, and adding about 15 per cent. for heavy, or subtracting nearly the same quantity for light lands, a fair estimation of the quantity of seed required per acre for any kind of soil may be arrived at. For permanent pastures about 2 bushels of the Grass seed and from 10 lb. to 12 lb. of mixed Clovers per acre are commonly recommended. But the quantity of seeds should in all cases be estimated by weight and not by measure; for the heavier the seed the better its quality and the less per acre will be required. Seeds relatively light are comparatively worthless, as they contain a large percentage of an unproductive kind. Grass seeds vary greatly in weight from about 8 lb. to upwards of 40 lb. per bushel.

The advantages of having land well prepared are numerous. Grass seeds require to be covered very lightly, and if just placed under the soil the less the depth the better. A far greater number of them will germinate at a depth of $\frac{1}{2}$ in. than at any greater depth, it being generally found that the number decreases with the depth of sowing, and living plants disappear altogether after about 2 in.

Where land is to be laid down with a mixture of Grasses and Clover seeds, these are better sown separately, or well mixed and run upon the land with the seed-barrow. Choose a dry and calm day, and finish up the operation with one turn of the harrows or the roller, as the texture of the land happens to be close and heavy or loose and light. Where the seeds are sown without a corn crop of any kind, the heavy roller may be advantageously used when they are about 3 in. high. New-formed pastures are better mown the first year, and for this purpose sharp scythes should be placed in the hands of expert workmen, otherwise some of the finer Grasses will be torn up by the roots. When grazed, turn on cattle and not sheep, and avoid treading during very wet or frosty weather. Whenever it becomes necessary to patch the pasture or to apply renovating seeds, apply a little compost at the same time, and well brush or drag and roll the land.

In selecting seeds for permanent pastures, either as meadows, lawns, wood-rides, &c., those should be chosen which have been found by experience to be best suited to the particular purpose in view. Thus, upon meadow land, an early and continuous supply of herbage of good quality throughout the summer is the main consideration; upon lawns, fineness of herbage and compactness of surface; and upon wood-rides, firmness. For medium soils of good quality I have found the following the most useful mixture: Meadow Fescue, Red Fescue, Darnel-leaved Fescue, Timothy, Perennial Red, and Smooth-stalked Meadow—1 lb. of each; Meadow Foxtail, Sweet-scented Vernal, Crested Dog's-tail, Sheep's Fescue,

Rough-stalked Meadow, and Alsike—2 lb. of each; Round Cocksfoot, Hard Fescue, Perennial Ray, and Yellow Trefoil—3 lb. of each; Evergreen Rye, Pacey's Rye, and Wild White Clover—4 lb. of each, or 42 lb. in all. By adding to or taking from the quantities in the foregoing list according to the character of the soil, a good thick sward may be obtained.

For plantation roads, where a firm unyielding sward is required, take the following mixture:—Timothy, tall Fescue, meadow Foxtail, and hard Fescue, 2 lb. of each; rough Cocksfoot and smooth-stalked Meadow, 3 lb. of each; sweet-scented Vernal and rough-stalked Meadow, 4 lb. of each; and of wood Meadow, 7 lb., or 29 lb. altogether.

Sometimes it is found expedient to lay down for a time portions of land which have been cleared out in the midst of the woodlands, and during a ride or ramble nothing is more enjoyable than a sight of the fresh turf of such a woodland lawn completely shut in on all sides by tall trees. Here the seeds must be suited to the nature of the cover. Where this is light the following proportions may be used: Sweet-scented Vernal, Meadow Fescue, Timothy, and Wood Millet, 1 lb. of each; Hard Fescue, Wood Meadow, Rough-stalked Meadow, Giant Birdsfoot Trefoil, 2 lb. of each; Perennial Red and Wild White, 3 lb. of each; White Dutch, 4 lb.; Cocksfoot and Evergreen Rye, 6 lb. of each; and Perennial Ray, 8 lb., or in all 42 lb. Where the cover is denser select of Creeping, Bent, Timothy, and Soft Meadow Grass, 1 lb. each; Tufted Hair, Rough-stalked Meadow, Wood Meadow, Evergreen or Hudson's Bay, Wood Millet, Giant Birdsfoot Trefoil, and Tall Meadow Fescue, 2 lb. each; Giant Brome and Wood Fescue, 3 lb. each; Fibrous Oat, 4 lb.; and Cocksfoot, 6 lb., or in all 33 lb. The foregoing mixtures will also form good cover for game.

A. J. BURROWS.

Pluckley, Kent.

SOIL EXHAUSTION BY TREE ROOTS.

WITH plants of any description that in a comparatively short space of time arrive at maturity, as, for instance, the various crops which attain their full growth in a single season, any deficiency of the nutriment requisite to their sustenance becomes soon apparent; whether it results from an absence in sufficient quantity of the elements essential to assist in building up their structure, or through an excess in the numbers which occupy the ground, the effects alike generally are seen at once, or rather I might say, the skilful cultivator has a knowledge of their needs, and is mindful beforehand to provide the necessary food and to see that the ground is not occupied by a greater amount of plants than it can fairly support. The soundness of this practice is so fully understood and acted upon that unless in the case of the most negligent cultivators it is now unusual to see a contrary course pursued, even with the commonest culinary vegetable. The same holds good in the case of the majority of cultivated plants that are longer in attaining maturity, or that keep on for a number of years yielding an annual produce, but to this there is one notable exception, and that is hardy trees, both those that are evergreen and those that are deciduous. I am not alluding to the management of trees grown for the production of timber, though with them the struggle for existence, consequent upon thinning being too long deferred, often inflicts permanent and irreparable injury; but I speak of those that are allowed to exist in pleasure grounds and other positions about dwellings and gardens mostly middle size in extent, whether intended as shelter belts, screens, or standing in the grounds for the effect which they produce. I feel no hesitation in saying that in the greater portion of places of the description referred to the trees are allowed to remain in a state, the result of which is to completely defeat the object in view. One would suppose it was unnecessary to point to the fact that for the purpose of a screen at a comparatively short distance in grounds of the character I am referring to, it is essential to have the trees thus employed well furnished with their full complement of branches down to the ground; instead of this, however, they are too often allowed to remain with their roots engaged in a life and death effort to extract the requisite food and water from the soil, which, through having had to feed three times the number it was capable of sustaining, in the end becomes so exhausted that the whole of the lower branches perish and become not alone unsightly but absolutely useless for the purpose intended. And if we come to the internal part of the grounds, where this very common course is followed, the condition of the trees is usually much the same as that of those on the outer portion, often not showing a single fairly-grown example that gives promise of continuing in a healthy state to anything approaching its allotted time; such trees, owing to their position, are often held in high estimation by their owners, who, by their unwillingness to part with any, allow them to remain in a state that will inevitably cause the destruction of the whole. They seem unable to see that the earth can no more sustain two plants where

one requires all the nutriment present than it can feed two animals confined on a space only large enough for one. The two cases are analogous; but trees do not show the positive effects of starvation so soon as animals do. There can be no question that half of any given number of trees, especially when occupying positions from which they can ill be spared, are greatly to be preferred to double the quantity existing under conditions wherein their food requirements are so far insufficient as to lead to their gradual but certain destruction.

Nothing less than sufficient room for the branches of a tree from infancy, and a corresponding space of ground unoccupied by the roots of other trees, can secure a healthy condition for the full period of its existence, yet it is surprising the efforts which trees are capable of making in order to repair the injuries which they have suffered when the causes by which they have been affected are removed, and in most cases, even where they give unmistakable signs of suffering from insufficient food through over-crowding. If the number be reduced so as to afford those remaining a chance of succeeding, they very soon show the benefit done them; and by this means, which rarely fails, unless in cases in which decay has gone too far, large numbers of trees that have got past their best would be so far invigorated as to attain and keep in fair condition for many years. It should not be forgotten that of trees in pleasure grounds, such as those under consideration, a great portion have their roots wholly in earth the surface of which is kept continuously mown without anything to counterbalance the impoverishing effects until the whole is as poor as it is possible for it to become, and with no opportunity of much being done that would strengthen their roots; if they, in addition occupy the ground in too close proximity to each other, the evil is very much intensified.

Where shrubs are grown over the roots of the trees new soil and manure in quantities sufficient to afford a good deal of assistance can be and frequently are applied with considerable effect, but the shrubs with their roots near the top are the first to take advantage of the manure and derive the greater benefit, especially in the case of many species of deciduous trees. It is to enough yet judicious thinning that I would point as the most effectual means for the preservation of trees in the places I have alluded to. The subject is worth consideration. By a sufficient expenditure, well laid out, a garden can be made satisfactory, so far as the ground and the shrubs go, but as for trees large and old enough to give character to a place, no possible outlay can do more than produce comparatively feeble results.

T. BAINES.

THE COTONEASTERS.

THESE consist of a goodly number of hardy evergreen, sub-evergreen, and deciduous low-growing trees and shrubs very diverse in general appearance. They are found distributed over Europe, Asia, and America; and several of the species have been long cultivated in this country, and are still extensively used in the adornment of our gardens and pleasure-grounds. Few shrubs or trees adapt themselves with greater facility to almost every variety of soil, if dry; and they are found to thrive in poor, gravelly, or sandy ground where it would be difficult to induce other plants of their character to grow. Though most of the sorts are perfectly hardy, they should always be planted in situations sheltered from the full force of violent winds.

Frigid Cotoneaster (*C. frigida*).—This is a sub-evergreen, or in mild winters and sheltered localities an evergreen tree, of about 20 ft. in height, indigenous to high mountains in Northern Nepal, from whence it was first introduced into this country in 1824. The leaves are of an elliptic form, tipped with a small spine, crenulated, of a dark shining green on the upper surface, and lighter below. The branchlets and under sides of the leaves are covered with a minute wool when young. The flowers are pure white, and small individually, but being produced very abundantly in terminal panicles, they produce a fine effect when in perfection, which is usually early in May. The small bright-crimson berries which succeed the blossoms are ripe in September, and hang on the tree till winter and sometimes till spring. It is a vigorous-growing, very hardy tree, and from its fine foliage and showy flowers and fruit, very desirable for planting either in groups, or singly in parks, shrubberies, or the margins of woods.

Allied Cotoneaster (*C. affinis*).—So named from its close affinity to *C. frigida*, of which some regard it as merely a variety. It is a sub-evergreen or evergreen tree of from 15 ft. to 20 ft. in height, introduced from Chittagong, Nepal, in 1828. The leaves are ovate, tipped with a small spine, bright green above, and woolly beneath. The flowers and fruit are almost identical with the preceding species, appearing about the same time, the berries hanging on the tree, and being very ornamental many months after ripening. It is an exceedingly interesting tree, well worthy of attention on the

part of those engaged in decorative planting, its distinct appearance giving quite a character to groups of low-growing trees or tall shrubs.

Simon's Cotoneaster (*C. Simonsi*).—This is a sub-evergreen shrub of from 5 ft. to 8 ft. in height, introduced from Khasya, in Nepal, in 1850. The leaves are oblong acute, dark green above, lighter beneath. The flowers are white, appearing in May. They are followed by a plentiful crop of bright scarlet berries, which ripen in September, and remain on the branches during the greater part of the winter. It is a remarkably hardy ornamental shrub, certainly one of the most attractive of the genus, in most seasons truly evergreen; and not only effective in the open shrubbery, but very suitable for covering walls or house fronts—its beautiful scarlet berries rivalling in beauty those of the well-known *Pyraecantha*. It is also found to make a neat, close garden-hedge, standing the knife well—a purpose for which it might be, with advantage, more extensively used.

Small-leaved Cotoneaster (*C. microphylla*).—This is a prostrate evergreen shrub, with long wiry stems, spreading over many feet when allowed full scope, but seldom rising above 2 ft. or 3 ft. It is a native of Nepal, where it is found on the rocky slopes of mountains. It was introduced in 1824. The leaves are small, oblong, of a thick leathery texture, dark green above, and slightly pubescent beneath. The flowers are white, similar in appearance to those of the Hawthorn; they appear in May or June, and are succeeded by scarlet berries, which ripen in August, and remain on all the winter. Apart from its value for planting as a single specimen on a lawn, where it soon forms a compact, cushion-like specimen, it is one of the most useful of plants for a low wall, the dense full foliage, twiggy branches, and bright berries in winter rendering it a very pleasing object. It is, moreover, a valuable rockery plant, and may be introduced with the best effect into any situation where a trailing evergreen shrub is desirable.

Thyme-leaved Cotoneaster (*C. thymifolia*).—Another prostrate evergreen species from Nepal, from whence it was first sent home by Dr. Royle in 1850. The leaves are much smaller than those of *microphylla*, about $\frac{1}{4}$ in. long, obovate-oblong in form, shining dark green above, and silvery white beneath. The flowers are small, pinkish, appearing in May, and followed by bright crimson berries, ripe in August. This is a very beautiful little shrub, perfectly hardy, and admirably suited for planting on rockeries. It might be utilised as an edging in the flower garden, as it has all the closeness of habit which renders the dwarf box so useful, with an appearance quite distinct from, and equally handsome with, that well-known plant.—“The Gardener.”

Protection of Wood from Rot.—In *Landswirthschaft und Industrie*, Herr K. Fleischer, of Gonobitz, thus describes his accidental discovery of a means of preserving wood from rotting. Four years ago he set about making a preparation of coal-tar and ashes for the purpose of driving away ground fleas and beetles from his garden. Just as he had mixed the materials together he was called away from his work, and, on returning, found to his surprise that, instead of tar in the ashes, there was a kind of woody texture in its place. Astonished at the transformation, he tried the experiment over and over again, and invariably with the same result. Just about this time he had occasion to refloor an outdoor room, where the boards came into almost immediate contact with the ground, and took the opportunity of testing the preservative effects of this mixture by smearing the under side of the planks with coal-tar, and sprinkling them liberally with ashes, a thin layer of which latter was also sifted over the ground. The procedure proved eminently successful, for the floor is still in perfectly good condition, and not in the least attacked by fungus growth, while on all previous occasions, though laid down in equally good material, it had always required constant repair in a very few months' time, and was generally thoroughly rotten in less than two years. Herr Fleischer has since tried the same application on the woodwork of hotbeds and forcing-houses with equally satisfactory results.

Elastic Waterproof Cement for Protecting Wounds on Trees.—Take one quart of fine North Carolina tar and boil it slowly three or four hours. Add to the boiling tar 4 oz. of tallow and 1 lb. of beeswax, and stir till well mixed, then remove the vessel from the fire and stir till the contents begin to thicken. Have ready 1 lb. of dry and sifted clay, and stir it thoroughly until you can stir no longer. In warm weather this cement is soft enough to be easily spread with the point of a knife. When applied to wounds on trees it completely excludes moisture, does not harden or crack or scale off, yields to the new growth, and can at any time in moderately warm weather be pressed by the finger into the corners and crevices of the wound which may be uncovered.—*Rural New Yorker*.

PLATE CXCVI.

ROSE JEAN DUCHER.

Drawn by the late Mr. NOEL HUMPHREYS.

JEAN DUCHER, the subject of the accompanying plate, may be said to be a representative Tea-scented Rose, both in form and colour. The fortunate raiser of this variety was Madame Ducher, of Lyons, and it was first introduced into England in the autumn of 1874. It is described in "The Rose Garden" as follows: "Growth very vigorous, flowers large, full, and globular; colour salmon-yellow, shaded with peach; a very hardy variety, succeeding well out-of-doors, and producing magnificent blooms under glass." As regards colour, the flowers vary considerably, and are often of a fine rich apricot with creamy edges, and this phase of the flower is by no means the least beautiful. No garden now-a-days could be considered well or judiciously planted unless it contained at least a small selection of Tea-scented Roses. Although the finer sorts may not grow and flower in perfection in cold, wet districts, Gloire de Dijon, Safrano, Sombrenil, Madame Berard, and perhaps half-a-dozen others as hardy but less beautiful, may be planted in company with and treated similarly to the Hybrid Perpetuals and other hardy Roses. The majority of Tea Roses should, however, have the protection of a wall with a south, east, or west aspect, and we fancy they not only look better but thrive better planted 1 ft. from the wall and trained into the form of dwarf bushes than when nailed to the wall. Tea-scented Roses revel in warmth and moisture when properly applied, and their beauty and fragrance are so bewitching that they are quite worth planting out under glass. If, too, they can have a house to themselves so much the better, as then the kind of treatment necessary to their highest development can be followed out without fear of injury to other plants. This, however, is not always convenient and there are many kinds which do not absolutely require it. Generally speaking, the free-growing varieties may be introduced into the stove, greenhouse, or conservatory, where they grow and flower well whether planted out or kept in pots.

A. W. PAUL.

Waltham Cross.

TEA ROSES IN POTS.

THE Tea varieties of Roses that have been out-of-doors since spring, and which are intended to open their buds under glass, when taken indoors must not have any allowed to remain on them that are likely to open sooner than they are wanted. The flowers of the Tea sorts come on very quickly after they are once formed, but the pinching off must be done with discretion; it must not be continued too long, or the flowers will be necessarily late. The kind of weather which we get through the autumn will to a considerable extent determine the treatment which the plants need in the above matter, the object with them being to furnish flowers so as to fill up the gap that occurs between the latest blooms produced by the Tea varieties on open walls and the first that come in from forced plants. They should not be housed sooner than the weather renders protection necessary, but they ought not to have the soil too much saturated by rain; if they could have a few loose lights placed temporarily over them they would keep them right and render it unnecessary to take them indoors, unless there was danger of their suffering from frost. On the appearance of mildew or aphides, means should at once be taken to destroy them, as whatever injures the foliage reduces the blooming capabilities of the plants accordingly. Roses in pots intended for forcing should also be kept quite clear from the pests just named, and they should not be allowed to have the soil soured by too much water. Hardy plants when in pots will not bear without injury the soaking from rain that they can withstand when their roots have free scope in the open ground. Where Roses are looked for regularly—and there is no time of the year at which they are more acceptable than late in the autumn, when flowers are scarce—there should always be a good piece of wall planted with the stronger-growing Teas. I prefer a south-west or west aspect for the purpose; under such conditions, where the plants are attended to with water in summer and kept free from insects and mildew, with the protection of a few mats or canvas on frosty nights, a supply of flowers can often be kept up in moderately favourable localities until near the close of the year, and the trouble is far less than that which is frequently taken with plants that give a much less return. In houses in which more or less of the Roses are planted out, they are often, after their blooming season is over, left for a time to almost take their chance; but when the foliage is allowed to become a prey to mildew and insects it is so much the sooner rendered useless to the plants, through which they are correspondingly weakened, whereas if a little labour is bestowed upon them they will amply repay it.

T. BAINES.

GARDEN ROSES AT CHESHUNT.

"WELL, what are they? May not all good Roses be called garden Roses?" By no means, if we take them with regard to their capability to fulfil the object for which ninety-nine people out of a hundred who grow Roses want them, and who, although fully capable of appreciating the beauty of the splendid flowers of which exhibition stands are made up, yet cannot afford to cultivate varieties that are indifferent growers, or so shy in flowering, that each individual tree or bush will not in many cases produce half-a-dozen presentable flowers for even ordinary cut purposes in a season. It is for want of understanding, or in forgetfulness of this, despite all that has been said on the subject, that so much disappointment is experienced by the many who, pencil and note-book in hand, are ever to be met with at an exhibition of Roses, taking down the names of the most perfect flowers there to be seen, generally without the slightest thought as to the vigorous constitution or otherwise of the plants that have produced them. There is, too, another matter of equal importance to those who cultivate Roses as they do other garden flowers, and that is, their continuity of blooming for as great a length of time as the season will permit; for the handful of half-open buds that may be daily gathered in the later part of the summer, although in many cases inferior to those that have preceded them in the height of the Rose season, are nevertheless often more prized. With a view to seeing the kinds that maintain this late-flowering habit during the present exceptional season, I went in the last week of August to look at the Cheshunt collection, and the following few notes are the result of my visit:

Amongst hybrid Perpetuals, Sultan of Zanzibar, dark maroon, flushed with scarlet, still retains its character as one of the freest of the free autumn bloomers, full of flowers and buds in all stages. Prince Arthur, deep crimson, was full of flowers and buds. J. Stuart Mill, bright red, one of the best. Duke of Connaught, fiery crimson, one of the best for all seasons early and late; a great favourite with the growers for market. Mrs. Laxton, rosy-crimson, very bright; extremely free flowerer; late. Schwartz's new Rose—A. K. Williams—let out last year, reddish-crimson (a Horace Vernet formed flower when that fine Rose is at its best), another of the most persistent late-bloomers. John Bright keeps well up to its character, and even at this advanced season the quantities of glowing crimson flowers which it carries make it conspicuous amongst its neighbours for some distance. Jean Liabaud, another bright crimson shaded with violet, is better now than in the earlier part of the summer: it is in the way of Abel Carrière, but not quite so strong a grower; the latter is also one that may be included in a select list of late bloomers. Beauty of Waltham, rosy-crimson, another of the best, is full of flowers and buds. Madame Lacharme, is one of the few whiter Roses that keep on flowering late. Camille Bernardin, light reddish-crimson, equally as good as an autumn bloomer as it is in summer. Boule de Neige, a grand old pure white Rose, which in form and habit of flowering may be set down as an exaggerated Aimée Vibert, and forms a splendid bush covered late with flowers. Dr. Andry, bright red. La France, full of flowers and advancing buds, with its foliage still fresh and green when grown on the Dog Rose, but completely over-worked on the Manetti, which to a considerable extent holds good in its similarly affecting other sorts. John Hopper, another old favourite and one of the best of late flowerers. Glory of Cheshunt, dark velvety-crimson, a new Rose not yet sent out; evidently one of the most continuous and late bloomers; it is all but evergreen, an immensely strong grower, forming a stout dense bush as strong as the free-growing Rêve d'Or, as shown by the parent plant raised from seed four years ago, and which is growing beside a very vigorous bush of Rêve d'Or. Duke of Teck, also a new variety not yet sent out, a fine constitutioned Rose, almost as strong a grower as the preceding; in colour it is the nearest approach to scarlet, and has all the appearance of keeping on blooming to the end of the season. Independent of what these two Roses may prove to be as exhibition kinds, it is evident they are acquisitions as garden Roses. The above, although not by any means exhausting the list of late flowerers, stand out conspicuously in the immense collection at Cheshunt as the best. Their foliage is ample and strong, resisting the attacks of mildew very much better than the weak-growing kinds. Respecting mildew I may here observe that the present season is quite an exception as to the absence of that parasite, giving undoubted evidence that when it spreads to a great extent, as usual in dry summers, it is in a great measure attributable to the insufficiency of moisture at the roots.

In the Tea varieties, which are the best of autumn bloomers, the following are amongst the strongest-growing free-flowering kinds that will in a single season form a stout bush capable of producing flowers in quantity:—Jean Ducher, (see annexed illustration); Perle des Jardins, straw colour; Marie Van Houtte, yellowish-white flushed with rose; Anna Ollivier, rose-tinted flesh; Madame Camille, salmon-

tinted pink; Catherine Mornet, flesh colour; Madame Villermoz, creamy white.

I noticed here an interesting sport from Baroness Rothschild, pure white, a counterpart in colour of Mabel Morrison, but a full Rose, whereas Mabel Morrison, as I have seen it, has not more than half the requisite number of petals. The Victor Verdier class of Roses, of which Captain Christy may be taken as an example, will not grow at all in the Cheshunt soil, and in a good many other places in such a cold season as this.

The work of budding Roses in the Cheshunt Nurseries is no slight affair; twelve men and as many boys tying have been engaged in the operation all through the season. A quarter of a million stocks of various heights and kinds were this year planted, and with the exception of those that have failed to grow have been budded, amongst them the seedling Brier, of which there are 30,000. The way this stock is operated upon may interest the uninitiated. The budders are preceded by boys who scrape away the soil below the collar of the plants to the depth of some 3 in., and it is in this smooth upper portion of the root that the buds are inserted. The advantage of this stock, not alone for Tea varieties, but for the great majority of Hybrid Perpetuals, is evident, as from the first it is well furnished with plenty of feeding fibres near home, enabling it at once to fully sustain the Rose worked upon it (so different from the half rooted standard stocks), and from the same cause it is much better able to bear transplanting with little check.

T. BAINES.

GARDENING FOR THE WEEK.

Flower Garden.

Auriculas.—Some complain of losses amongst their plants this year. If the plants were out of doors no doubt the drenching rains would rot the roots, but no Auricula fancier would trust his plants out of doors in such a season as this. Under glass the greatest pest to them is green fly, and it is astonishing how soon this insect will spread over a frame and destroy the plants. We were nearly losing some valuable plants from this cause alone this year; the pest spread over the under sides of the leaves so much that they were nearly covered with them. Whenever a trace of green fly is seen it ought to be destroyed at once. Water should now be carefully administered; no plants should receive any unless they are actually rather dry at the roots; the woolly aphid that attacks the roots will be likely to appear on plants that have become rather checked from lack of root moisture, and the necessity of keeping all the plants rather dry at the roots will further encourage the pest. Lose no time in shaking all the soil from the roots and washing them well with soapy water, afterwards washing them with clean water. It is easily destroyed.

Carnations and Picotees.—Layering if not yet done should now be finished as soon as possible. There have been great losses amongst the plants this year. Weak growers have succumbed altogether to the inclemency of the weather, and I hear of some cultivators who have nearly lost their entire collection of all sorts. It is very desirable that seedling raisers should save their seeds from plants with strong constitutions as well as from those that have the finest flowers. Quality in the flowers is of great importance, but this is of little use if the plants cannot be kept in good health. The old yellow ground Picotees were of such weak constitutions that it was almost impossible to retain them in collections from this cause. Now we have the new strain introduced by Mr. Turner, of Slough, possessing higher points of excellence than have yet been attained in the flowers, whilst as regards constitution it is as good as that of the border Cloves.

Pinks.—See that the plants raised from pipings in boxes are now planted out in a warm position, allowing about 4 in. between each plant. The Pink in its young state likes a fine sandy soil, and in planting press it rather firmly round the roots. We had much difficulty in getting good pipings this year, and have taken the old plants out of their beds and replanted them; to plant out again in their permanent position early in October.

Hollyhocks.—No further instructions are wanted as to culture than those given a few weeks ago. The late damp weather caused the flowers to decay almost as soon as they opened; if these are not removed at once they are unsightly. Cuttings of scarce varieties may be put in as soon as they can be obtained, either as eyes from side branches or shoots from the base of the plants. Seedlings may yet be planted out to bloom next year. Usually late plants, if fairly well established, stand the winter better than those that are too strong.

Pansies.—These are now being much sought after, and they will deserve all the attention which they receive. See that a goodly

supply of cuttings is put in, so that there may be a good reserve of them retained in boxes under glass. We lost two-thirds of our named varieties last winter from wet and frost combined. If the plants are not required to make good boxes in winter, there are always plenty of less fortunate neighbours glad to accept them.

Polyanthuses.—The plants that were potted from the open ground a fortnight ago are now making plenty of new roots round the collar, and this cannot happen without a corresponding top-growth. All they require now is a good supply of water at the roots, and keeping the leaves clear of green fly and red spider.

Hardy Cyripediums.—The leaves and stems of these plants have mostly died down now, and when this happens growers are sometimes recommended to dry them off, which is often another name for killing them. The beautiful *C. spectabile* is not likely to be dried off in a wild state, and why should it undergo that process under culture? I plant some species of Moss over the surface, and this is kept green and growing; the soil is always moist, but not so much so in winter as it is during the summer months. It is unwise to repot them just yet—rather delay repotting until after the shortest day is past. Merely keep the plants cool and moist at present.—J. DOUGLAS.

Indoor Fruit.

Vines.—Early Vines that are to be started into growth in November ought now to be at rest, a condition which will be more effectually induced by early pruning; at the same time, such pruning ought not to be done till the wood is hard and brown, and the foliage manifests a disposition to die off naturally. If the borders require any renovation, now is the time when such work should be done, and outside borders should be either thatched, covered with shutters or lights, in order to throw off rain and prevent the roots from getting chilled. Inside borders, which are always preferable for early or late Grapes, must not, even though the Vines are at rest, be allowed to get sufficiently dry for the soil to crack, but for a time the border may advantageously be kept on the drier side of a medium state of moisture. Pot Vines intended for early forcing should now have full exposure to the atmosphere. A south wall, on which the canes can be tacked, is the best position for them, and heavy rains can be warded off the pots by placing slates or tiles over them, but avoid over-dryness. It is still cold, sunless, and wet, and Grapes that are fully ripe require as much attention with respect to the removal of bad berries as is usually the case in November. Under the circumstances, fire-heat and air, on every favourable occasion, are the best aids to good preservation. If ever the weather deigns to be favourable again, disperse with fire-heat at once, and give all the air possible. Constant fire-heat is still an absolute necessity in order to ensure ripeness in late Grapes before the end of this month. Keep the laterals thin, to allow all the light possible to play on the fruit, for without it perfect colour is unattainable, particularly in the case of Mrs. Pince, Lady Dowdes, and Gros Colman.

Pines.—Pot culture of these has at least one great advantage over the planting-out system, viz., that of admitting of a number of plants of about the same stage of growth being arranged in separate compartments and given the treatment best adapted to any particular period of growth; and at no other time of the year more than at present is the separation of plants in the different stages necessary. For instance, many Queens have completed their growth, and now require to be kept comparatively both cool and dry to ensure their showing fruit when started in December; others of the same variety are in full growth, and require a free supply of humidity and warmth; whilst those swelling off fruit require special treatment, both as to airing and watering; hence the advantage, and indeed the necessity, of being able to group the varying growths in separate compartments. There is still so little sunshin that plants fruiting must have abundance of artificial heat to induce them to swell rapidly. Deformed fruits and improperly developed pips are oftener the result of checks received through sluggish growth than from the want of root moisture; at the same time care should be exercised in order that there may be no lack in that respect. The bottom heat ought not to be less than 80° or the top heat lower than 70° on the coldest nights; the closing-up day temperature may reach 95° with an heat. Succession plants in free growth, such as those that are expected to fruit during July and August next year, ought to have the same liberal treatment as those swelling off fruit; but guard against a weakly growth—first, by giving air freely whenever the weather is suitable, and next by affording the plants plenty of space in the beds. Those that have their pots full of roots and that have completed their growth now require a short season of rest, induced by a partial withholding of moisture both at root and top, and this, with free ventilation, will at the proper time have the desired effect, that is, of causing them to show fruit as soon as heat and moisture are renewed. Suckers that were taken from the early

summer-fruiting plants will now require repotting in order that the roots may get well established in the larger pots before the advent of winter. They require a brisk bottom heat and very little water till the roots have started into the new soil; but they may have a syringing overhead daily at closing-up time. Shade the plants from the direct rays of the sun for a week after repotting.

Figs.—In most cases the second crop of fruit will now be approaching maturity; syringing must therefore be discontinued and a circulation of warm air constantly kept up to impart flavour. Should sunless weather still continue, fireheat must be applied, and this will enable air to be given night and day. If the borders are inside they must not lack moisture, and what water is given must be at least of the same temperature as that of the soil—a few degrees warmer would be all the better. Outside borders will need coverings to throw off heavy rains. No further stopping of shoots will now be required; but after fruiting any naked shoots may be cut right out, and this will give the new growths a better chance of ripening. Trees in pots that have been placed in the open air will require protection from the heavy rains which we are constantly having; indeed, if such weather continues much longer, they should be again placed under cover.

Peaches and Nectarines.—It will be difficult to get the wood of these fully ripened in late houses this season, for the growth is both more profuse and more luxuriant than usual, and this in spite of an extra amount of stopping. The only way of aiding maturity will be as soon as the fruit has all been gathered to cut out all useless spray and shoots, tying out the remainder thinly, and then to apply artificial warmth, accompanied by a moderate amount of ventilation, till the wood begins to get brown and hard; the trees may then be gradually inured to bear full exposure. Though the fruit is gathered, inside borders must still receive good supplies of water, and syringing must be resumed to keep down insects, and so preserve the foliage in a healthy condition till the fruit-buds are well developed. See former notes as to the requirements of early and succession houses.

Strawberries.—The dull wet weather which we are still having is inducing a strong sappy growth, which will be most difficult to ripen; hence, seeing that sunshine is so great a rarity, other steps must be taken to attain maturity. First and foremost, the plants should have abundant space, in order that air may play about the foliage. The pots should be occasionally lifted, to prevent any roots entering the ashes or gravel on which they are placed, which would not only cause greater leafage, but delay the period of their getting root-bound, for until that takes place the maturity of the crowns is very problematical. As to placing them under glass, very few have that convenience; certainly we have not, but if we had, this is the kind of season in which we should do so. Keep all runners persistently pinched off, and pull out weeds as soon as perceived, for if left to get large there must necessarily, on their removal, be a certain amount of mutilation of surface rootlets. If after heavy rains any are water-logged, turn out the plants and rectify the drainage, for there can be no healthy root action whilst the plants continue in such a condition.—W. W.

Kitchen Garden.

In a well-managed kitchen garden what is termed the busy season extends throughout the year, but if there ever were a slack time it would be during the present month, when, for the most part, all winter crops have been sown or planted, and others, such as Onions, Potatoes, &c., harvested. This year, however, any spare time will need to be utilised in the destruction of weeds which abound in all directions, and oo wonder, seeing that there have not been throughout the whole spring and summer six days consecutively of fine weather. It has, therefore, been impossible to use the hoe for their destruction, and though handweeding is a slow process, it is the only sure preventive of an abundant crop of weeds another year or even years, and this prospective evil should act as an incentive to getrid of them by some means or other ere they seed. All Potatoes of whatever kind ought now to be lifted. All ours have been got up, and I regret to say that the yield is not more than half of that of last year, whilst of most varieties quite two-thirds are diseased, and of the following kinds there is not one sound tuber: Crampian, Rector of Woodstock, Blanchard, and Cattell's Eclipse. Of the following kinds there is not a diseased tuber, and consequently these only will be grown in quantity next season, viz., Advance, a handsome Kidney of fine quality; Sutton's Magnum Bonum, another excellent late Kidney; Vicar of Lehan, a blue-skinned flattish-round variety, partaking both in form and quality of Paterson's Victoria, and a round seedling sent here for trial by a firm of seed merchants, and which is, in all respects, excellent. The following kinds were but slightly diseased, viz., Early Rose, Myatt's Ashleaf, Schoolmaster, Emperor, and International. The Winter Greens and Broccoli planted between the

rows of Potatoes will now require earthing up. Regarding the utility of this practice there can be no doubt that it is highly beneficial, both as a support against wind and as favouring the production of a large amount of stem rootlets, which are of the greatest service to the plant. Continue to plant all ground as it becomes vacant either with Coleworts, Cabbages, or Sprouting Broccoli. If not yet sown in sufficient quantity seeds of the following vegetables should be got in at once, viz.: Chick Castle and Black Stone Turnips, Bath Cos and Hardy Hammersmith Lettuces, Early French Horn Carrots, Turnip-rooted Radishes, and Winter Spinach. Thin out former sowings as early as the seedlings can be handled, and keep the surface soil about them open by hoeing whenever the ground is sufficiently dry to admit of that being done. August-sown Cauliflower plants ought not to be left in the seed bed to become drawn or weakly; a good sturdy plant that will winter well can only be ensured by pricking out early. If the ground be ready for them, those that are intended for wintering under the protection of handlights may be planted in that position at once, and the lights can be put over them any time before there is danger of injury from frost. Generally we get finer Cauliflowers, and very nearly as early, by wintering the plants at the foot of a south wall, and planting out as early in March as the weather will permit. The cold nights, sunless days, and excessive rainfall are too much for late Peas and French Beans; they do not grow a bit, and therefore those of the latter in pots and frames must be pushed on as quickly as possible, and other sowings should be made to keep up a successional supply. There will not now be much wheeling or other traffic likely to injure walks or paths, and all should therefore be made tidy. Box edgings should be clipped, also hedges and all decaying vegetable refuse should be removed to the manure heap.—W. W.

Extracts from my Diary—September 8 to 14.

FLOWERS.—Potting a few more *Bouvardias*. Re-arranging plant houses, and otherwise putting them in good order. Cutting out Brier suckers. Putting in cuttings of *Pelargonium Manglesi* and Mrs. Pollock. Potting Roman *Hyacinths*. Looking over *Pelargoniums* in boxes and picking off decayed leaves and flowers.

FRUIT.—Gathering Lord Burghley Apples. Sweeping Peach trees in houses with a new broom to divest them of leaves in order to ensure wood ripening. Gathering all ripe Peaches and Nectarines. Looking over Strawberries and pulling off all runners and decayed leaves. Straightening verges of walks in orchards. Gathering King of the Pippins, Warner's King, and Roinette du Canada Apples, and *Beurré d'Amanlis* Pears for dessert. Tying and stopping Melons. Gathering Marie Louise Pears for dessert. Watering Vine border in late house. Cutting out shoots and leaves of Figs to admit light and air.

VEGETABLES.—Thinning Turnips sown for winter use. Sowing main crop of Prickly Spinach. Looking over Haigh's Kidney Potatoes in pits to see if any are diseased, and removing any that are infected. Gathering Scarlet Runners, Radish pods, Onions, &c., for pickling. Sowing Mustard and Cress. Cultivating ground preparatory to planting winter Lettuce. Soiling Mushroom bed with about 1½ in. of loam. Earthing up Celery. Sowing Wood's early frame Radish in prepared frame. Turning Onions on beds to dry. Storing Onions away in chamber for winter. Cutting off stems of Globe Artichoke and hoeing and clearing ground about them. Preparing soil for Mushroom beds. Sorting Magnum Bonum Potatoes and storing away seed. Sprinkling a little lime over Onion beds and cultivating ready for planting Cabbages. Tying winter Cucumbers. Pulling up old Pea haulm and manuring ground for winter digging.—R. GILBERT, *Burghley*.

Coal-ash Walks.—Good, sound, dry walks are a necessity in all garden grounds, in order that the work necessary in them may be carried on with comfort during all weathers, and although their is nothing like good gravel for walks in pleasure grounds, it frequently happens that, from the difficulty of getting gravel in quantity within a reasonable distance, the kitchen garden walks have to be made of whatever is most abundant. After trying all sorts of materials in different countries, it was found that nothing makes a better path than ashes. The way in which we use them is to form Grass verges 1 ft. wide and about 1 ft. deep. In the bottom of the walk are put brickbats, stones, or other rubbish. On these a good layer of clinkers is spread, and broken down tolerably fine, when a good coating of sifted coal ashes is spread evenly over the surface, and rolled down. These form one of the pleasantest paths on which to walk, wheel, or cart that it is possible to have. Weeds are not troublesome, for the material has been changed by passing through the furnace, and if a few seeds blow on to the surface and germinate, they can be easily removed.—JAMES GROOM.

THE KITCHEN GARDEN.

ASPARAGUS CULTURE.

(Continued from p. 171.)

Planting.—We plant Asparagus both in the spring and autumn. The autumn plantings do not succeed in light soils; most of the young shoots die down during the winter, and those which resist present but a wretched appearance. In cold climates autumn planting meets with but little better success, even in the case of dry soils; this is due to the fact that Asparagus, being a succulent plant, does not grow in the winter like woody-fibred plants, and that it very often rots when it is placed in the ground too soon. It is only in southern climates that it may be planted in autumn or winter. Whether you plant in beds or borders, the proper position of each stool must be marked off with the measuring line and dibber. Having completed this part of the operation, bring a little light soil over the part marked, so as to form a little mound as shown at *MM* (fig. 4) of about 2 in. in height, and in the form of a flattened sugar-loaf, continuing the operations to the end of each line. You next take a stool and spread it out on the little mound, arranging the roots in such a manner that they neither touch nor cross each other, covering them up to a depth of from 3 in. to 4 in. with fine, light soil. Press the soil down firmly over the roots so as to bring them close together

Fig. 5.—Asparagus trenches after planting.

so that the stool may not be disturbed, as well as to drive out all the air from beneath the soil, and the operation is finished. It now only remains for us to fill up the empty spaces between the mounds with earth, smoothing the surface of the bottom of each trench with the rake level with the line *B*, as shown in fig. 5, that is to the depth of 4 in. Fig. 4 shows a section of the beds before they are planted, and fig. 5 a section of them after the operation has been completed, with the exception that the stools and mounds are shown while they are really covered up by the soil which has been taken from the mounds, where they formed an angle on a level with *HH* (fig. 5). The stools consequently are covered up as far as the dotted line *B 10* that is to say, to the depth of an additional 4 in., including the little mounds which have been flattened down by the superincumbent pressure, and are now only from $\frac{1}{2}$ in. to 1 in. thick. For planting under walls on the level surface we dig holes of 8 in. in depth, refilling with 1 in. of light earth, and plant according to the directions given above, filling up with $3\frac{1}{2}$ in. to 4 in. of earth. Small mounds are placed round the plant so as to attract the humidity of the soil, if it is dry, and on the mounds must be formed others, or the Asparagus heads will be too short. Some authors recommend that the stools should be planted as soon as they are pulled up, but this is an error, for Asparagus takes root much more readily when it is faded. Like all succulent plants it is apt to rot if it is planted when quite fresh. It has also been observed that plants sent from a distance strike root much more easily than those taken from a plantation close by, and produce much better heads. We have ourselves planted on the 16th of April stools which were taken out of the ground on the 20th of the previous February, and the plants which they produced were in all respects most satisfactory.

TREATMENT OF YOUNG PLANTS.

First Year.—The operations to be performed during the first year are limited to keeping the Asparagus plantations constantly free from weeds, hunting down the *Crioceris Asparagi*, as explained farther on, and placing sticks at the bottom of each stool as soon as the stems are 18 in. or 20 in. high. For the latter purpose we insert a little stick of wood at 12 in. or 14 in. from the stool so as to avoid all danger of hurting the roots, bending the stick over until it is in close proximity to the shoot we desire to protect. At the point where the stick touches the shoot we tie them together with a piece of bast or other tying material. This operation is for the purpose of preventing the wind from disturbing the stool in the soil by shaking the shoot backwards and forwards. This precaution is very necessary in localities exposed to high winds, but it is much too often neglected, and the Asparagus suffers accordingly. Where Asparagus is grown on a large scale, this support is dispensed with, the stool being covered up with fresh soil in the month of July. As it often happens that late shoots issue from the stools, they also should be fixed to a support as they come up. This operation is also unnecessary when the plant is grown on a large scale. If very dry weather sets in, we may throw on the stools 3 in. or 4 in. of soil taken from the mounds. The rain and the action of the hoe cause the soil of the mounds to fall into the trenches, so that the stools which were once covered with 4 in. of soil, at the end of the season become covered to the depth shown by the line *c*, fig. 5. In the month of November the surface of the trench is brought down to the level of the line *B*, fig. 2, or even below it, by throwing back the soil on to the mounds at each side before manuring.

Second Year.—In the month of March, after having dug up the mounds, we throw a few inches of earth into the trenches, raising the level to between the lines *B* and *c*, or even up to *c* (fig. 5), but not higher. In performing this operation we must be careful not to touch the young shoots, which will have just been formed, for if we hurt the stool the crop is endangered. During this year the same ordinary operations of weeding, hoeing, &c., are performed as described in the directions for the first year, keeping a sharp look-out for the advent of the *Crioceris*. In the month of November the trenches are dug up by taking up the soil as far as the line *B* (fig. 5) if the stool has not become raised, but in such a manner as to leave a good 2 in. on the roots. We then scatter throughout the whole length of the trenches either well-rotted manure, oil cake, or artificial manure in the proper proportions, throwing back the soil on to the mounds, as in the first year. The winter being over, the trenches are filled with from $1\frac{1}{2}$ in. to $2\frac{1}{2}$ in. of earth, so as to bring them to the level of the line *B* (fig. 5), making the arched tops as high as the line *D*, describing the curve shown by the dotted line. Before making these mounds we must take away the old shoots by detaching them gently from the stool.

Third Year.—During the third year we proceed as during the first, with the exception that if the plantation has prospered we may gather our first crop, taking only two or three heads, but not more, from the healthiest-looking stools. In the autumn the trenches are cleared in the same way as in the first two years, and the mounds then are manured, as will be described presently. The mounds are lowered as during the first year, but we must only manure lightly. The weaker-looking stools are marked with a stick, so that they should not be earthed up in the coming spring, and so have nothing gathered from them. As for those which are strong and healthy we stick two or three old Asparagus heads into each stool, taking one out for each young head that we gather, so

as to keep count of the crop. This is only done during the first year.

Fourth Year.—This year's operations coincide absolutely with those of the second year, with the exception that we may gather one crop during a period of three weeks, taking care, however, not to try the weaker stools too much. The trenches are manured during the winter, and when spring arrives we scatter over them a little soil, so that the stools may be buried to a depth of about 5 in. For this operation we must refer the reader to the Calendar of the Asparagus Cultivator.* From this period the stool producing its roots at the collar has a constant tendency to raise itself. It is for this reason that, having cleared it of soil in the autumn and earthed it up again in spring, in fifteen years the mounds will be lowered entirely to the general level of the beds, as indicated by the line *h h h* (fig. 5). In order to earth up the stools, we are consequently obliged to take the soil away from the mounds, which, so to speak, now become lower than the stools themselves. The earthed-up stools now reach to the height of the line *e* (fig. 5), and even to the line *r*, if the beds are very old. Early Asparagus rises, as a rule, about $\frac{1}{2}$ in. per annum, and the Late about half that distance.

List of operations to be performed after the fourth year :

- 1.—In November take away the tall shoots after having cut them away about 12 in. below the soil.
- 2.—During the winter we must break down the mounds at least every three years.
- 3.—Rebuild the mounds.
- 4.—Manure must be distributed.
- 5.—Make up the bottom of the trenches at the end of the winter (say from the 15th to the 20th of March), by covering them with 3 in. or 4 in. of soil that we took out of them and threw on the mounds in the autumn.
- 6.—Towards the end of March take away the old heads and form arched-headed mounds of 7 in. or 8 in. in depth over the stools.
- 7.—Hoe as often as necessity requires it ; but, whether weeds are troublesome or not, the whole ground should be well hoed four times a year from March to October, namely in April, June, July, and September.
- 8.—Break down the small round-headed mounds immediately after the crop has been gathered, except high winds are liable to break the shoots, in which case it is better not to unearth.
- 9.—Support the shoots with sticks if necessary, but this is not needful when the plant is produced on a large scale.

Digging.—Under this heading may be included both the breaking down and building up operations connected with Asparagus culture, as well as the frequent hoeings which must be practised. The hoeings are a kind of superficial digging which only penetrated a slight depth below the surface, and are performed by means of a shallow hoe or even a rake. The other two operations are performed with the large hoe and flat-toothed fork. This latter instrument is but little known and used, but it is of the greatest possible service, and we recommend it highly to Asparagus growers.

Shallow Hoeing is a very simple and very easy operation, so well known as not to need description. We ought, however, to remark that it is essential to use a very light tool and not to disturb the earth to so great a depth as is done in certain localities. It is only necessary to penetrate to a depth of about $\frac{1}{2}$ in., so as to cut off the weeds at the crown. If we hoe more deeply than this we shall not only bring up to the surface a number of seeds which will promptly ger-

minate, but we shall cut the weeds too far below the collar, at the same time pushing them back again into the soil, so that after the next shower of rain we shall be surprised to see a large number of them lifting up their heads once more. Digging operations require a much greater amount of attention than light hoeing. The labourer, armed with his fork, sits astraddle on the mound and stirs up the soil at the sides, throwing a little of it behind him without destroying the shape of the mound too much, and taking care not to hurt the roots of the Asparagus plants, which he may easily do if he works below the surface of the soil in the trenches.

In sandy situations, or very soft soils, there are certain strong-growing weeds that the flat-toothed fork is powerless to destroy ; in this case the large broad hoe must be used, but it requires long practice to handle this implement properly. It is a very tiring tool to use, but it completely moves the earth, for it makes a hole like a spade. The hoe has the advantage of not interfering with the form of the mound, so that it leaves no work behind it. But, in spite of every precaution, the form of the mound is more or less spoiled by digging operations, so that it must be restored to its original shape by the aid of the flat hoe or the small hoe. Careful growers overturn their mounds every year ; others, every two years ; while others only perform this operation once in three years. There is no doubt, however, that the more the earth is disturbed the more active is the growth of the plants.

Manures and How to Use them.—By adopting the method of culture described above, we need only use a comparatively small amount of manure, hardly double the quantity of that employed for root crops—Potatoes, for instance. All manures are apparently good for Asparagus ; there are, however, certain precautions to be taken in using them. For instance, farm-yard manure should not be employed in too fresh a condition, as it would affect the roots and certainly spoil the crop for two or three years. We must also beware of employing other manures of too active a nature, such as lime, sheep's, asses', or mules' manure in too large doses. We may obtain excellent results on certain soils by using a double dressing composed of one-half stable manure and one-half dried blood, guano, burnt seaweed, &c., but it must be tried on a small scale before applying it to the whole plantation. The ingredients are not to be mixed together, but applied separately, the blood, guano, or seaweed being used first. A good deal has been said about the use of common salt in Asparagus culture ; but we have tried it several times without being able to come to any exact opinion on the subject. We should consequently advise Asparagus growers to make a trial of it on a small scale before applying it to the whole of their beds, in order not to run the risk of accident. There are two methods of applying manures—the first by placing them in the trenches ; the second by distributing them over the mounds. The following is the general mode of procedure : We must always be careful to manure either before or at the beginning of the winter, in order that the rains may have time to dissolve the more soluble portions and carry them down to the roots. If we defer the application of the manure until spring, the good effects of it will scarcely be apparent, or it will not be perceived until a year has elapsed. When we adopt the system of dressing the trenches, we begin by taking off the top of the small mounds, and, this being done, we spread the manure throughout the whole length and breadth of the trench, taking care to keep the stools free from it, and more especially the spots from which the young heads will spring, as the immediate contact of manure of any kind with them will rust them and render them unsaleable and uneatable. The quantity of manure to be used varies according to circumstances. In the case of short stable manure,

* See a future number of THE GARDEN.

from which all the long straw has been removed, it is applied in a layer of from 1 in. to 1½ in. in thickness across the whole width of the trench, or only from 16 in. to 20 in. in length, according to the age of the stools. At Argenteuil a cubic foot of night-soil is used for every five or six stools, that is to say, about a cubic yard for every 140 stools, once in two years. In spring, the soil which was taken during the process of unearthing, is replaced, so that the manure now becomes covered to the depth of from 3 in. to 4 in. In manuring the mounds we must begin to open them up as soon as possible, that is to say, towards the end of October. This is effected by cutting a number of trenches 14 in. in width and of such a depth as to reach to the bottom of the main trenches without injuring the roots of the plants. The soil which is taken out of these small trenches is deposited in the main trenches between each stool of Asparagus, so placed as not to cover up these latter; in fact, so that it may be gathered up again when necessary without endangering the young shoots which mark the position of the stools. These small trenches being made, the manure is thrown into them to a depth of at least 2½ in., the extra soil is replaced, and the mounds are trimmed up. The trenches are opened up either with the flat hoe or with the spade. The flat hoe is the most difficult to manage, but the work is done much quicker than when the spade is used. We should advise Asparagus growers to use the flat hoe in localities where the soil is pretty free from stones. In stony soils the trenches are somewhat difficult to open up, and we are sometimes obliged to have recourse to the large-toothed fork to stir up the soil, which is afterwards carried away by the shovel. In the latter case we must manure much more generously, and only undertake this operation once every four or five years, in order to avoid a too frequent recurrence of the expense and inconvenience it gives rise to. It may be performed during the fourth, eighth, and twelfth years.

GODEFROY-LEBŒUF.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Lettuces Seeding.—The crop of home-grown Lettuce seed this year will be very partial—indeed, as far as the Cos kinds are concerned, probably a failure. The Cabbage kinds invariably start earlier, but even these have had their blooms so much washed by the rains as to render the production of seed doubtful. As evidence of the shifts to which our market gardeners are driven to obtain seeds of their famous Cos strains, I remarked a few days since near Kew in a large garden, where Lettuces are grown in enormous quantities, that over a quantity of flowering plants high stakes had been fixed tripod-fashion, and beneath these and over the heads of bloom were suspended large bell-glasses or cloches, to protect the bloom from the heavy rains. This is, however, but a small matter in the mass of cultural difficulties with which market gardeners have to contend this season.—A. D.

Mushroom Beds.—The best season for making up Mushroom beds has now arrived, and where a winter supply is desired a succession of good beds made up of sufficient thickness to retain the heat for a considerable period should be made at once. If the manure is sweet and in good condition a temperature of from 80° to 90° is not too much, and some efficient means of keeping the house up to from 55° to 60° should exist, or the spawn will not run, but remain dormant until spring, and possibly be condemned as useless.—G.

Autumn-planted Potatoes.—A "Country Parson" writing in the *Times* the other day states that "generally speaking, the best time to plant Potatoes is late in October or early in November. The reason for doing this is not far to seek. Potatoes, if stored in a cellar until spring, shoot forth long roots or filaments, called by different names in different counties, and thus expend their vegetative power before they are planted, and are thus far more liable to disease. They are, in fact, sickly Potatoes; and matters are not much mended by storing seed Potatoes in a garret, for there they shrivel, and thus lose much of their strength; whereas, if planted in the autumn, they are kept alike from the outward air and from growth, and thus come out of the ground in the spring much stronger

and better plants than those that are put in early in spring. I have planted my Potatoes in autumn for the last thirty years, and thus speak from experience. Autumn planting was new to the farmers in my neighbourhood, among whom I introduced the practice, who all declare they never will give it up, as it yields a better and safer crop. All one has to do is to plant the Potatoes 2 in. deeper than in the spring. A farmer who planted his crop last autumn after this fashion told me that 'not one Potato missed,' and the winter was both hard and long enough to try Potatoes and most other things."

Tomato Disease.—The identity of the Potato disease with that which affects the Tomato is unquestioned. The plants are members of the same family, and evidently subject to the same diseases. It is only within the past four years that the disease has shown itself upon the Tomato to any appreciable extent, but last year it was so destructive that acres of plants were quite destroyed ere a ripe fruit was produced. When it is thus prevalent, plants grown in the open ground—that is, trained to stakes or laid on straw—have no chance whatever. It generally shows itself in the Tomato as soon as the Potato haulm has disappeared under its destructive operations, thus showing that it prefers to exist upon the Potato before it attacks the Tomato. This year Tomatoes are very late, and the prospect of getting a crop of fruit is rendered very doubtful by the gradual progress of the disease over the leafage. As for a remedy, there is none at present, and the only way to get a good crop is to grow Tomatoes under glass. Even here, however, if much exposed to the air or especially to drip, the disease will soon show itself. I found it to be so last year under frame-lights, and the same indications of disease in the Potato under glass were also shown where there was drip. That the minute spores or germs of the fungus are carried in the air and in rainfall there can be little doubt.—A. D.

—The disease is a fortnight later in making its appearance this year than last. I first saw it on August, the 29th. It will, however, cause no loss in regard to the crops, as we shall not cut a fruit out of doors large enough for use this year. Last year the disease destroyed most of the crop outside; experience of this sort shows one the advantage of having some under glass. Just recently I saw some producing useful fruit in a Peach house planted between the trees on the back wall, the trees being half standards, or one may grow them in large pots, tying them to stakes, or planted out in cold frames, putting a trellis of some sort to run over; they deserve to be more extensively grown under glass than they are seeing how useful they have become and the length of time during which they continue in bearing. From one set of plants last season grown in pots, trained to the back wall between some young Peach trees in a house, we cut good fruit from the middle of June to the middle of March, and at the end of December all green fruit was cut and put on shelves to ripen. We have some now in the same place doing well, and if we have them equally long we shall not feel the loss of the outside crop. The sorts which I grow are Trophy, Hathaway's Excelsior, and Green Gage.—J. F. C.

Lifting Potato Crops.—Now that the Potato disease has set in, in all quarters strong arguments are adduced in favour of early lifting and storing, but in the main I agree with "A. D." (p. 206), that, except as regards a few early sorts, it is not practical to lift the main crop for winter and spring consumption in time to be of any use as regards warding off the disease. This year Potatoes, like other crops, were late in making their growth, which was at its height when the disease suddenly struck them. The American Rose and other soft, heavy-cropping sorts were quite leafless in a few days, and many of the tubers were more or less affected according to the nature of the soil; the heavier and more retentive as regards moisture the worse they are. Early Kidneys, such as Veitch's Ash-leaf, although checked in growth, have not become so badly blighted, and the latest crops of Regents and Victorias have continued to grow, although the haulm is partially affected, and must, therefore, check and reduce the amount of crop; but as far as lifting crops with the view of saving them from disease is concerned, there is little to be gained, as if the disease is in them, although not perceptible, they will be sure to rot, whether lifted or left in the ground. I find the Victoria Regent to resist the attacks of the disease and to keep healthy in the haulm the longest of any of our main crop varieties.—J. G.

The Benefits of Excursions to other localities where others are following similar pursuits to our own are not to be measured by the profitable hints we may pick up, but there is a mental and bodily relief that comes from a change of scene which will allow one to return to the later work of the season refreshed, and with a spirit of content, for one who travels with his eyes open cannot fail to see that others, as well as himself, have their discomforts and drawbacks, and he is all the more disposed to meet his own with a brave spirit.—*American Agriculturist*.

THE INDOOR GARDEN.

NEWLY-IMPORTED ORCHIDS.

UNTIL recently the importation of Orchids was usually confined to nurserymen and a few private individuals who happened to have friends out in the Eastern or Western Hemispheres where the more popular kinds are plentiful. Those that were imported by nurserymen used generally to be kept in their possession until they had made more or less growth, and thus become established before being sold, but the vast quantities now brought into the country are sold by thousands almost weekly as soon as they arrive before sufficient time has elapsed for them to have made any growth. These get into the hands of beginners as well as those of experienced growers, and I may here observe that were I bringing together a collection of these plants I should very much prefer good stout imported plants—not the infinitesimal bits into which they are often divided—to confining my purchases, as frequently used to be done, almost exclusively to plants that had been long in the country, often during the time in several hands subjected to very different treatment, which not unusually was anything but calculated to give them a robust character, in the absence of which they are of little value. One advantage in imported plants is that they will succeed with much less shading, more air, and less heat, all conducive to continued healthy vigour, than Orchids long in the country, the whole existing growth of which has been made under conditions the reverse of these, and which, if subjected to treatment such as that recommended for imported plants to be grown under glass, would, in all probability, make little progress, or rather for a time grow smaller instead of larger by a considerable loss of their soft watery leaves. There is something more than this in imported Orchids, as there is also a sort of fascination in uncertainty, especially where the chances are that something better will turn up, and in nothing is this more fully exemplified than in the case of imported Orchids, amongst which many of the finest forms and varieties are continually making their appearance. The majority of newly-imported Orchids are anything but in a condition that gives them an inviting appearance, as they are almost invariably much shrivelled, dirty looking, and to the uninitiated in such a state as would give little hopes of their regaining strength and vigour. The desire to make them start into growth, especially in the case of those who have had little to do with plants in a similar condition, is often fatal to them, inasmuch as if they are at all hurried the chances are that they will die outright. The treatment given is too frequently based upon what the temperature during the growing season would be in the countries from which they come; but it should be borne in mind that Orchids, although most tenacious of life, have, when they reach this country, been usually for months subjected to ill-usage, and any undue hurry under such conditions is almost certain to result in failure.

When Orchids come to hand in the state in which imported plants ordinarily are, the first operation should be to cut away all dead portions of both leaves and roots, being careful in this that not a particle of either which has any vitality in it is removed; then the whole should be sponged over to free them from dirt and any insects that may be present. The artificial heat requisite to be given them will, as a matter of course, be dependent upon the time of the year at which they arrive and the countries from which they come; if cool kinds, such as will thrive in a temperature like that given to the majority of *Odontoglossums*, the warmth of an ordinary greenhouse will suffice, and if in the summer time lower than that, and the atmosphere should be kept considerably more moist, for the object is first to get the leaves and pseudo-bulbs into a plumper condition, which, as they have few or no active roots, can only be brought about through absorption by the leaves. To effect this in most cases it is better to lay the plants on some material that will hold moisture slightly than to suspend them from the roof; but to preserve the moisture in the atmosphere necessary to the plumping-up process just alluded to, it will be requisite to reduce the admission of air somewhat, and also to shade them when it is bright and sunny, but not to keep them so dark, or with the atmosphere so close and stagnant, as is sometimes done and from which bad effects follow. I have found nothing better upon which to place newly imported Orchids whilst thus recovering from their journey than a close-jointed stage of rough unplanned boards, which hold much more moisture than those that have been planed or painted, thus reducing a good deal the need for wetting the plants directly overhead. They are sometimes put on a layer of Sphagnum and it answers very well, but it should not be kept too wet, especially for the first week or two after the plants have arrived. Such Orchids as *Vandas*, *Aerides*, *Saccolabiums*, and *Angrecums* are often suspended head downwards, the object of thus inverting them being to prevent water lodging in the crown or axils of the leaves. I have found all such species to do best hung up against

a wall where the air would naturally be more stagnant than that in the body of the house where there is more circulation, but this of course will all depend upon the condition in which the house is kept in respect to air. The custom with many is to allow the plants to remain in this way until they have commenced to make roots, but that is a mistake, for the young roots are so tender and susceptible of injury that it is impossible to pot them, and almost as difficult to attach them to blocks or pieces of wood, after they have begun to move, without damaging their root points. As soon as it is seen what will grow and what will not, I should recommend those progressing being at once attached to pieces of wood proportionate to the size of the plants, in all cases allowing the wood to which they are fixed to have sufficient length below the plants to admit of its being made firm in the pot and sunk well down into the drainage crocks and potting material. This making the plants quite firm in the pots is a matter of very great importance, for if they are so loose as to shake about when touched or the pots moved, the young roots before they lay hold of the soil will be sure to receive injury; for the same reason it is obviously necessary to pot them before their roots have pushed so as to admit of being damaged in potting. Quantities of valuable Orchids that reach this country with sufficient life in them to grow and get established I feel convinced are continuously sacrificed through not seeing that the first attempt at root formation receives no check, for the effort thus made—often feeble and weak—is frequently the last which the plants are capable of.

With *Cattleyas*, *Lælias*, a good many *Oncids*, and *Epidendrums*, the first season's growth, particularly in the case of plants that have suffered much in coming, or that have been divided into small bits, will be quite as satisfactory if fastened to blocks proportionately large for their roots to lay hold of, and with a little Sphagnum attached to assist in preserving sufficient moisture about them. By being kept thus suspended and out of pots until the first summer's growth is completed, or rather till the time when they are near commencing to grow the year following, when they may with advantage be potted, for with the exception of the comparatively few species found to succeed better altogether on blocks than in pots, there is no doubt that the sustenance which they receive from the peat and Sphagnum, used as potting material, into which their roots penetrate, enables them to get much stronger than they do when the extremities of their roots are unattached. This may be easily confirmed by observing the growth that a *Cattleya*, *Lælia*, or similar plant makes when it has extended beyond the limits of the pots, and the whole of its roots cling to the outside, or are not attached to anything.

In the case of strong, stout pieces of Orchids of this description, such as *Cattleyas* or *Lælias*, I have found it best to pot them at once previous to making any growth, as thus frequently a considerable portion of the young growths will flower, and the plants with little loss of time become established specimens. In like manner with the thick-rooted section, that is the true air plants, of which *Aerides* and *Vandas* may be taken as representatives, they should always be potted previous to either whatever living roots they may retain, when brought over, beginning to extend, or the formation of any new ones, for, having no pseudo-bulbs to support them, they are even more impatient of injury to their roots than those which have. With *Phalenopsis*, wherein the whole plant consists of the leaves, a short bit of stem, and whatever living roots they may yet have, the chances of recovery except when received in a tolerably fresh condition are much less than those of the generality of other species. With them it is best to attach the plants to pieces of wood as soon as they have been subjected to the sponging and cleaning process directly they arrive; after that placing them in positions such as those suggested for the others, where they will be most likely to commence growth without delay, yet without hurrying them, will suit them perfectly. *Dendrobiums*, from the fleshy nature of their pseudo-bulbs and naturally greater vitality, usually bear the rough treatment entailed in bringing them to this country better than other Orchids; but in their case all dead portions of bulb and root should be cut away, and when properly cleaned they ought to be at once fixed to stout pieces of hard wood, such as will, as with the others, admit of being secured in the pots, and all that show indications of growing should be at once potted or placed in baskets, according as their habit of growth is erect or drooping, or the way in which they are intended to be grown, for it is well to bear in mind that erect-growing kinds, like *D. densiflorum*, *D. nobile*, and others of simple habit, are alike benefited by being hung up close to the glass, as are the pendent growers. *Cypripediums* and others of similar character should in like manner, as soon as their leaves commence to fill up a little, be potted before any roots begin to move, being careful that no water lodges in the axils of the leaves until growth has commenced in earnest. If a course such as this is followed with imported Orchids, treating them in a way that will slowly but gradually restore their weakened energies, and induce them to make growth, and, what

is of equal importance, also seeing that their first efforts at root-making are not interfered with, many valuable plants that otherwise would be sacrificed will be saved.

Pleiones.—As their new bulbs approach full size, gradually withhold water, but by no means cut off the supply too suddenly or before they are fully mature and plump, or it will seriously interfere not only with their flowering, but with their increase next year; as their breaking double seems a good deal to depend upon their previous season's growth being well ripened up before the leaves decay.

Sobralias.—These large gorgeous-flowered subjects are not now held in the estimation they once were; still there are few more effective plants in a collection, for though the individual flowers do not last long, when the specimens get strong they keep on giving a succession of bloom for weeks, and the fresh green appearance of their reed-like shoots contrasts admirably with the generally more quaint-looking forms. As the young growth approaches its full size, the bloom-stems that have flowered may be cut away, which will give more room to the advancing shoots. It is not well to remove them too soon, as it manifestly cannot but weaken the plants. It seldom happens that red spider causes much trouble amongst Orchids, but Sobralias are sometimes attacked by it, especially towards the autumn, when a somewhat drier atmosphere is being maintained. Their presence will easily be detected by the under leaves looking yellow and unhealthy. Where the pest happens to exist, clean water, if persevered with, applied through the syringe, laying the plants down on their sides, and turning them over, will clear them.

T. BAINES.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Eupatorium ligustrinum.—Where cut flowers are in request during the early winter months this plant should be grown. It is of very easy culture, and may be quickly grown into good large specimens. It is easily propagated from the half-ripened wood, the cuttings to be inserted in sandy loam and placed in a close frame. It will also strike readily in early spring. If a plant or two are placed in gentle heat they will furnish an abundance of cuttings. The most expeditious and easiest method of cultivating it is to turn it out during the summer months into a free, rich piece of soil—if of a rather stiff, loamy character so much the better, as it there acquires a more sturdy and vigorous habit than when planted in soil of a light description. A very sunny, exposed situation should be chosen, so that the wood may thoroughly mature, and the flower-heads be well advanced before the plants are taken up for potting. In hot weather they need copious supplies of water, and an occasional soaking with liquid manure will materially assist them. If the plants are kept well stopped in the early stages of growth, and plenty of space allowed for development, robust specimens—some 4 ft. high and 3 ft. through, well furnished to the base with foliage, and covered with bloom—will be the result. Such plants, when placed in a cool house at housing time, furnish an enormous quantity of flowers. I once grew about a score of large specimens, and when in bloom they certainly presented a very pleasing appearance, and were found to be of great service for supplying cut bloom, the entire sprays being well adapted for table decoration, and the individual flowers, when mounted two or three together, were useful in bouquets.—J. C.

White Lapagerias.—I presume that Mr. Baines doubts my statements (p. 132) with regard to the propagating of these plants. I can only suggest that he should visit Handsworth Nurseries when he has an opportunity, and see for himself. He will find, I think, that his experiences in the matter have been surpassed. I wish to say, however, that when I said it would be found the best plan to propagate Lapagerias like pot Vines, I did not mean the plants to be struck from eyes, but layered annually and potted. I am aware that propagation by means of single eyes or cuttings is a slow process, and have condemned the practice before in THE GARDEN. As to the number of shoots on two-year-old plants, Mr. Baines states that "even in the case of the very strongest plants it takes some time before one or two annual shoots are made." In reply to this I can only state that in the house to which I referred, I counted eleven shoots on one plant, and this and the other plants I was assured by Mr. Sibray, one of the members of the firm and the propagator, were layered from eyes in the autumn of 1877, potted last year, and again shifted on into large pots during the present season. Whether this particular plant was the red or the white variety I could not now be sure, as the house contained both kinds. There is a fine variety of the red Lapageria at Handsworth, as well as a white one, and this is extensively propagated also in the same manner as the white one. Here we have a white plant of the same age with nearly as many shoots, great and small, the

longest about 11 ft. or more. The number of shoots on these two-year-old plants is not so wonderful, in my opinion, as the number on the young ones, which produce even more in proportion to their age. Why did Mr. Baines give directions not long since in his "Gardening for the Week" for the management of plants from cuttings, when, according to his own showing, he had proved the superior advantages of the layering system "thirty years ago"? Permit me to say in conclusion that I did not make use of the expression given between inverted commas by Mr. Baines as mine. I said "some of these plants have ten shoots or more." I am not conscious of having exaggerated anything.—J. S. W.

Anguloa eburnea.—This is merely another name for a pale-spalled form of *A. uniflora*, otherwise also called *A. virginalis*, but in nowise structurally distinguishable from *A. uniflora* of Ruiz & Pavon's "Flora Peruviana," Syst. p. 228; Fl. Peruv., Prodr., p. 118, t. 26; Lindl. Gen. et Sp., p. 160, and of which a characteristic figure was published in the "Botanical Register" of 1844, t. 60. This plant, together with the pale golden *A. Clowesi*, Bot. Reg., 1844, t. 63, and the yellow blood-spotted *A. Ruckeri*, Bot. Reg., 1846, t. 41, is a native of New Granada and Columbia. Bateman, in the "Second Century of Orchidaceous Plants," t. 159, figures and describes *A. uniflora*, and remarks that "there are many varieties of this species, some of them of a purer white and much larger than others." The particular variety of *A. uniflora* he described as above is referred to thus:—"The flower is a dirty cream colour, tinged and spotted chiefly within with pink." Doubtless it is this tendency to variation which has induced horticulturists to give pseudo scientific names to the finer or supposed finer varieties of *Anguloa uniflora*, a practice too often resorted to at the present day in the case of other species, even by botanists themselves as well as by certain trade growers. Mr. J. Douglas (see p. 190) is perfectly right; any other *Anguloa* known with wholly white flowers. "No! nor any other Orchid either." Britten & Gower in "Orchids for Amateurs," p. 222, attribute the specific name *eburnea* to Hooker, but do not give references, and it is just possible that it is a mere garden name. The name *A. uniflora* is, in the same work, attributed to Reichenbach—perhaps in error. Both these authors and also Mr. Williams's descriptions are sufficiently vague, and neither is bold enough to tell us that *A. eburnea* and *A. virginalis* are really and simply reflections—albeit beautiful ones—of our old friend *Anguloa uniflora*! What a hecatomb of pseudo-specific names the Orchidologists of the future will make! *A. virens* is another ghost—indeed a name only, a greenish white, or as Bateman puts it, a "dirty cream" coloured sort. *A. uniflora* may in some badly-named collection have the name tacked to it, but the whole usage of applying specific Latin titles to mere varieties of species, as in the case in point, is becoming a decided nuisance injurious to the generous enthusiasm of Orchid-growing amateurs, and thus ultimately baneful to the prestige of trade growers themselves.—F. W. B.

— I am much obliged to Mr. Douglas for his descriptions of *Anguloa uniflora* and the variety *superba*. With this species, however, I am well acquainted, having known and grown it for upwards of twenty-five years; the variety has sometimes deserved the name of *biflora*, as twice I have had it with two flowers on the same scape. What I desire to know is this, if the plant known as *A. eburnea* is synonymous with *A. uniflora*. If not, what it is like; and, seeing the plant in question named by Mr. Baines, I thought that he knew it; it appears, however, that he does not, but opens another question by saying that the plants he has known by the name of *A. eburnea* do not differ from *A. virens*, a species which, judging by its name, should have green flowers, which I have neither seen nor ever heard of; what can it be?—Z.

Phalænopsids.—Mr. F. Goldring last week in referring to *Phalænopsis Lobbi* gives as a synonym *P. intermedia* Portei. I have always held these plants to be distinct. Will some one tell me if I am in error? *P. intermedia* (Lind.) is the same as *P. Lobbi* (Veitch), and appears to partake somewhat of the characters of *P. amabilis* and *P. rosea*, the petals being dotted and spotted at the base with crimson; whilst the plant known as *P. intermedia* Portei is entirely destitute of these spots, the lip also being differently marked. More recently another form of *P. intermedia* has been introduced, called *Brymcriana*; can any of your correspondents enlighten me as to its points of difference?—Z.

Indian Periwinkles from Seed.—We find these very useful for decorative purposes, in the form of small plants raised from seed sown in moderate heat in March, and if grown on in a medium temperature, they form bushy little specimens for summer or autumn decoration; after that they should be kept rather cool and dry, or should have just enough moisture to keep the foliage fresh until the days begin to lengthen, when they should be pruned back to the desired form, be placed in a moist growing temperature, and as soon as fairly started into growth they should be shaken out, and

reotted in rich soil. After that they will make rapid progress, and few plants form better shaped specimens than these Periwinkles or Vincas. By merely pinching out the growing points of shoots that are out-stripping each other, they may be grown into perfectly symmetrical proportions without any staking or tying, a practice that should be discouraged as far as possible in plant culture. The white kind with a red centre, generally called *V. elegantissima*, makes a striking object in groups of stove and greenhouse plants in summer. The principal enemy which these Vincas have is red spider, and that should be kept down by syringing, and above all by maintaining a vigorous growth by means of liberal applications of liquid manure, and maintaining plenty of atmospheric moisture in the structure in which they are grown.—J. Groom, *Linton*.

Ipomæa decora—This is a new Convolvulaceous, herbaceous plant, introduced from Eastern Tropical Africa by Mr. J. M. Hildebrandt. It has a large tuberous root-stock, and annual, erect stems about a yard high, clothed with silky hairs. The leaves are broad and oval, with thick nerves, and the white flowers with a reddish centre are traversed by yellow bands in the folds, and they are about 4 in. in diameter. There is a coloured figure of this plant in the "Monatsschrift des Vereins zur Beförderung des Gartenbaues," where it is stated that it flowers in winter. It is allied to the climbing species *I. albiivenia* and *I. Gerardi*.—W. B. HEMSLEY.

New Seedling Heath.—At the Byfleet Horticultural Exhibition, Messrs. Jackson & Son, of Kingston, staged a specimen plant of a new unnamed hard-wooded Heath. It is the result of a cross between *Marnockiana* and one of the best of the early flowering kinds, and will certainly become, when better known, a great favourite for summer and early autumn decoration. The flowers are bright rose, and are produced in the greatest profusion, and the habit is all that can be desired. Those who are in the habit of growing for autumn exhibition would do well to look to this variety, as a well-grown specimen forms a very telling feature in a collection.—J. C.

***Cyclamen europæum* as a Pot Plant.**—This hardy species of *Cyclamen* is well worthy of the attention of plant lovers. The flowers are so delicately and deliciously fragrant as to render it a highly desirable plant for pot culture. It may now be seen in bloom on the rockery at Kew, where, however, owing to a restricted root run, but a faint idea can be formed of its capabilities. It enjoys when in the open ground a well-arranged sheltered situation; but where the roots can find an abundance of nourishment it is easily grown in pots, succeeding admirably plunged up to the rim in a cold frame during the winter, and placed in April in a shady situation. In August it commences to throw up its pretty bright flowers, the exceptionally sweet perfume of which renders it highly acceptable for window or conservatory decoration. If placed in a north aspect, it will last a long time in bloom.—C. B.

Neapolitan Violets.—Any one desirous of having a supply of these lovely flowers during the winter months should look well now to keeping their runners cut close off, or they will monopolise all the energies of the plants; if kept to single crowns like Strawberries success for forcing is certain.—J. GROOM.

Perpetual Carnation La Belle.—The sweet, pure white flowers of this Carnation are invaluable for cutting, and a very easy, expeditious way of working up a stock is to put in the cuttings or pipings now under a handlight at the north side of a wall or fence of any kind, where it will be cool and shaded. If a large number are required a frame and lights will answer as well. Make a bed 6 in. in depth, of fine, light, rich soil in the frame, press it down moderately firm, scatter a little sand over the surface, water, and leave it for an hour or two to settle and drain. Dibble the cuttings in 2 in. apart; keep the soil in the frame in an equable state as to moisture, occasionally dewing the tops of the cuttings over with a fine-rosed pot during hot, dry weather, and every cutting will root, and be fit to pot up by the end of September. Pot into small pots singly, and place on a shelf near the glass in the greenhouse, and pinch back any strong shoots till they are potted into the blooming pots in spring, or as may be necessary. I like to place five plants in an 8 in. pot, or a larger number in a 12-in. pot, to make large specimens. They may also be grown singly in 6-in. pots, but they are not so effective. Most of the Tree or Perpetual Carnations may be planted out in summer and be lifted and potted in autumn. But I have always found this kind to do best when grown altogether under glass, and it will stand a high temperature if the plants have plenty of light. I think it best to strike a lot of young plants annually, selecting the strongest and healthiest cuttings available, as young plants produce the largest flowers.—E. II.

Lofty Tomatoes.—A resident in California is now gathering ripe Tomatoes from the top of a 20-ft. ladder. The Vine, which is 25 ft. high, has been trained on the sunny side of the house, and shows blossoms and fruit in every stage of growth.

AMERICAN NOTES.

THE JAMABUKI OR RHODOTYPUS KERRIOIDES.

(A JAPANESE SHRUB.)

JAPAN has greatly enriched our collections of hardy shrubs and herbaceous plants, and while a number of the shrubs from that country are well known and popular, we find that others, equally meritorious, are seldom seen in cultivation. If one takes up a catalogue, and finds "Rhodotypus kerrioides, a fine shrub from Japan, with the habit of *Kerria*, but with large white flowers," as there is nothing in the announcement to attract the attention of those who do not know *Kerria*, one in making his selection passes this by, and the nurseryman concludes that there is no demand for good things. It is a fact, and we may as well accept it, that people in general do not take to botanical names. However unreasonable this may be, and however we may show that some botanical names, such as *Magnolia*, *Geranium*, and others, are in common use, the fact remains that if we would popularise a plant, we must give it—unless its botanical name happens to be one like *Coleus*, which every one can remember—a name that will take. For this reason, in calling attention to a useful and showy Japanese shrub, *Rhodotypus*, we have been at some pains to hunt up its native name, and give our readers the choice between the botanical *Rhodotypus*, meaning "Rose form," and the native Japanese name *Jamabuki*. There is but one species of *Rhodotypus* thus far known, and it has been named *kerrioides*, from the marked resemblance of the foliage of the shrub to that of *Kerria japonica*, the old "Japan Globe Flower" of our gardens, which makes itself almost a weed, and which is still known in some catalogues by the incorrect name of *Corchorus*. The "*Jamabuki*," or *Rhodotypus*, is a perfectly hardy shrub, flowering in April, its foliage being so much like that of *Kerria* as to warrant its name; but the flowers, instead of the deep yellow of *Kerria*, and their flimsy texture, are of the purest white, and much larger and firmer. The plant belongs to the *Rose* family, and, unlike most of the showy members of that, it has but four petals, the usual number being five. The fruit consists of (usually) four little stone fruits, like the grains of a Blackberry, and according to Siebold and Zuccarini, who first described it, becomes of a brilliant black colour, and remains so until the middle of winter. We have had the plant in cultivation for several years, and find it one of those easy-growing things that have every element of popularity. It is not particular about soils, does not get so rampant as to need much checking, and forms a shapely bush, which in early spring shows an abundance of pure white flowers, which last a reasonable time. It is equally deserving of a place in the shrubbery with the *Weigelas*, which are now deservedly popular.

"Shut your own Gate behind you!"—When you leave your garden, fruit patch, or grounds, of whatever kind, *shut the gate*, and leave whatever is behind it, there—don't take it with you. Recollect that when you visit the place of another, you go to see what *he* has to show, and learn what *he* has to teach. If you would be a welcome visitor, and be dismissed with a pressing invitation to come again, place yourself in a receptive mood; be for the time the attentive pupil and not the teacher. When others visit your place, will be the proper time to teach. Of all the intolerable bores who visit us is the man who brings his own place with him, and who, whatever may be shown him, at once institutes a comparison with his own, and begins to tell that "mine are much better than that,"—"I can beat you on so and so," and ignoring the thing before him tells us, "Ah, you should see my Strawberries," "my Roses," "my Tomatoes," and so on all through—in short, the man who does not "shut his own gate behind him." Those who are so thoroughly satisfied with their own that they cannot forget it for a few hours, should not visit, but remain upon the scene of their remarkable achievements—at home. We would not imply that one in visiting the grounds of another, may not, on occasion, drop a useful hint drawn from his own experience, or that he may not give his host any information that he may ask for. But we have been so annoyed at receiving visitors, and worse still, in visiting strange grounds in company with those whose only object in visiting appears to be to boast of their own affairs, that we feel called upon to protest against it. Those who thoughtlessly fall into this unpleasant error, need only to be reminded of it, and they will sensibly avoid it. From the chronic boaster of his own achievements, we hope to be delivered.

The Oleander Poisonous.—The different varieties of the *Oleander* (*Nerium Oleander*), so popular as house plants in cool climates, are in warm countries often cultivated as ornamental trees, and used as hedge plants. The tree, in a suitable climate, will reach the height of 20 ft. to 30 ft., and forms a most beautiful object, both in its leaves and flowers. But with all its attractiveness, it has the

misfortune to be highly poisonous, a quality not so likely to be manifested when grown as a house plant, but one which becomes of serious importance when it is in common cultivation in the open ground. Some months ago, one of our correspondents in Bermuda, where Oleander hedges are very common, wrote to ask if the tree could poison the herbage around it, as he had found that animals that grazed near the Oleander hedge were frequently made seriously ill—a trouble which might be readily caused by a few fallen leaves. Later accounts come from another British colony, New South Wales, of the death of six cows at Sydney; the animals were fed upon grass recently cut from a lawn on which the Oleander grew, and its leaves became mingled with the fodder. It is quite likely that the poisonous principle is more active in climates which will allow the plant to grow continuously in the open air; still, while we do not remember to have heard of any casualty from house plants, it is well to know of the danger and be on guard against it. St. Louis, Mo., may also be called the City of Oleanders; such is their abundance, that it would seem that every house has one or more bushes, and the markets are gay with them. We should expect accidents there, if anywhere, from the plant. A case is recorded in Europe, in which fatal results followed eating meat in which a skewer of Oleander wood had been used.—*American Agriculturist*.

Hanging Baskets.—Allow me to tell your readers how to make hanging baskets at a slight expense, at least for less than the actual cost of such articles bought in stores, and, to my mind, they are then no prettier than those made at home. Procure a wooden bowl, a stray rusted tin basin or wash dish, which is the best shape for the present purpose; cover the outside with a coat of putty, and place on it, in rows, groups, or clusters, little shells. A row of tiny "dust-pan" shapes are pretty for a border. The contrast of the green leaves drooping over the white shells is very pretty. Or, if shells are not to be had, a "pounded" mixture of bits of different coloured glass pressed into the putty makes the uninitiated believe your basket to be made of diamonds, especially when the sun is shining on it. The "Snowflake" baskets, made of ravelled white cloth, look cool and hint of spicy woods and nodding Violets through the long winter, if filled with Ferns and hung in some shady window. Gather the Ferns while green and fresh, and pile them on a platter, or even a board; cover them with thick, wet Moss, and they will keep moist and green during the winter, to replenish the baskets or vases. Try it.

Magnolia parviflora.—A new Magnolia must necessarily be a valuable acquisition when we think of all the estimable qualities possessed by the various members of this family or genus. But what is *Magnolia parviflora*, to whose merits we wish to call attention? With little difficulty we might conceive it a nobler and better form of *Magnolia glauca*, one of our most charming native Magnolias. The flora of Japan, indeed, offers types very similar to our own, and in this case the similarity has been sufficient to induce Siebold and Zuccarini to call the plant in question a variety of *Magnolia glauca*, and Maximowicz speaks of it as resembling *glauca* more than anything else. But do not fancy that it bears a very close likeness to *M. glauca*, for the flower and foliage are all constructed on a larger and more effective scale. The leaves are often more than 1 ft. long, oval, of a bright green on the upper surface and whitish on the under, after the manner of Magnolias generally. Otherwise the form of the leaf is somewhat unique, bearing no special resemblance to that of any Magnolia. The flowers are borne but sparsely, and because they are found only here and there on the bush the name *parviflora* may have been given. Certainly the flower is not small, fully equalling that of *Magnolia tripetala*. The petals are arranged in a cup-shaped form, like those of *M. glauca*; are about 4 in. long and of a pure, solid, creamy-white colour, like those of *M. conspicua*. Inside, however, the appearance of *parviflora* is still more remarkable on account of the extraordinary development of the pistils and stamens. These parts of the flower are peculiar in most Magnolias, but in *M. parviflora* they attain an unusual size and brilliancy of hue. The pistils, in a solid cone, rise out of a bed of stamens six or seven rows deep. The base of these is a broad belt of crimson, and the anthers are of the same colour. In fact the whole general tone of both pistils and stamens is more or less brightly crimson. But the most remarkable qualities of *M. parviflora* are its delightful spicy odour and the peculiarity of blooming in mid June. So penetrating and agreeable is this odour that the first plant which bloomed in this country in April last, in the greenhouse of Messrs. Parsons & Sons, distinctly scented the entire building 100 ft. long. Its fragrance is much more penetrating than that of *M. hypoleuca*, and in many ways *Magnolia parviflora* differs greatly from *M. hypoleuca*. In short, the vigour of the growth of *parviflora*, the lateness of its period of blooming, and its delightful, penetrating, spicy odour must eventually secure it a high place among hardy plants.—*Rural New Yorker*.

GARDEN DESTROYERS.

THE CELERY FLY.

(TEPHRITIS ONOPORDINIS.)

LATE in the summer and in the autumn it may be often noticed that the leaves of Celery and Parsnips have a very withered and blighted appearance; on closer examination it will be found that the discoloured leaves are much blistered, and on holding one up against the light a grub or maggot nearly $\frac{1}{2}$ in. long will be seen between the skins of the leaf; this is the grub of the Celery fly, which lives on the softer portions of the inside of the leaf. This withered appearance of the leaves is generally attributed to some atmospheric effect, such as a cold wind, heavy rain, hot sun, or anything else remarkable in the weather, without taking any pains to discover the real cause; but by taking a little trouble in investigating things of this kind, the root of the evil will generally be discovered. This insect not only attacks the leaves of Celery, but also Parsnips, Alexanders, and several other large Umbelliferous plants, which suffer quite as much as the Celery from their attacks. When the grubs are present in large numbers, as is often the case, the plants are

A portion of a Celery leaf showing the blisters formed by grubs of the Celery fly. Fig. 1.—Chrysalis magnified. Fig. 2.—Perfect Insect magnified. Fig. 3.—Grub magnified. The lines show the natural sizes.

very much injured by the loss of so much foliage, and become weak, sickly, and stunted. The grubs may be found from the middle of June to the end of November, and as there are two or more broods of this insect during the season, it is very desirable that the grubs of the first brood should be destroyed, so as to prevent, if possible, any future generations. This is rather troublesome, but it may be done very effectually by pinching that part of the leaf where the grub is between the finger and thumb, or cutting the infested leaves off and burning them. Mr. Rose, of Byfleet, has tried watering his plants with the following mixture, which proved most successful: Two boxes of Gishurst Compound, and 1 lb. of Pooley's Tobacco powder, dissolved in water, and added to 36 gallons of boiling water. This should be thoroughly mixed, and then allowed to stand for twenty-four hours; the affected plants should then be well saturated with it. This can be best accomplished by watering them thoroughly with a pot which has a very fine rose; this method effectually kills the grubs. Mr. Curtis suggests that a dressing of gas-lime, soot, wood ashes, or lime applied to the surface of the ground about the time when the grubs are likely to be quitting the leaves would probably kill them when they reached the ground. This insect's natural enemies are few; they are probably free from the

attacks of birds when in the grub state; but, even securely as they would seem to be hidden in the leaves, two small members of the Ichneumonidae find them out and deposit their eggs in their bodies, causing the destruction annually of great numbers of them. It is almost impossible to do anything effectually towards exterminating this insect in its other states; the eggs are very small, and being laid between the skins of the leaves it is almost impossible to detect them. The flies may be caught with a butter-fly net, but I doubt if the few that would be captured would make any perceptible reduction in their numbers. As the chrysalides are formed in the ground they are practically out of our reach. The Celery Fly belongs to the Natural Order Diptera, or two-winged flies, the Order which contains the gnats, house flies, daddy-long-legs, &c., and is classed in the same family as the house flies. It is a very beautiful little insect, with particularly brilliant green eyes. In itself it is most harmless and inoffensive. It may be found from the end of May till the end of July, hovering over flowers, or basking in the sun in warm situations on palings and leaves, particularly on Laurel leaves, with its wings slightly raised and partially open, which it quietly waves up and down as it runs about with a jerky, half-sideways action. The female is provided with a longish ovipositor, which she can protrude or withdraw at pleasure. With this organ she pierces the leaves and inserts the eggs singly. These soon hatch, and the grubs which are produced at once begin feeding on the juicy interior of the leaf, thus separating the two skins, and causing the blistered appearance; often two or more grubs are so near together that the blisters in the course of time join one another. The grubs do not keep eating their way straight ahead, as the mining caterpillars of some small moths do, forming a regular track or gallery, but they appear to eat all within their reach, and work sideways along the line of untouched leaf, which generally is somewhat in the form of a segment of a circle, and gradually eat their way onward, leaving behind rows of their droppings. When fully grown the grubs work themselves out of the leaves, and drop to the ground, when they at once bury themselves and become chrysalides; those which are formed late in the season remain unchanged until the following May, when the perfect insects, bursting their fetters, crawl to the surface. The fly is about 2-10ths of an inch long, and measures 4-10ths of an inch across the expanded wings. The general colour of the entire insect is a yellowish-brown, but sometimes the body is darker. The head is furnished with a pair of small antennæ, consisting of only three joints. The eyes are large and prominent, and of a deep shining green. The thorax is oval and shining, with a few stiff black hairs on either side. The body is egg-shaped, each joint being fringed with fine brown hair. The wings are large and much clouded with yellowish-brown markings, which vary much in size and intensity in different specimens. Immediately behind the wings, in the place where the second pair of wings would be in four-winged insects, is a pair of small organs, shaped like drum-sticks, called halteres or balancers, the use of which is uncertain, but they are generally supposed to be the representatives of the second pair of wings. The grubs, when fully grown, are about 4-10ths of an inch in length, and are long and narrow, being very pointed at the head and gradually widening towards the tail, which is bluntly rounded; they are roundish and plump, pale green in colour, very shining, and so transparent that their intestines, &c., are clearly visible down the middle of the back as a broadish dark line. The grub is entirely destitute of eyes or legs; its body is composed of eleven joints, which are not very readily distinguished; the mouth is armed with two hooks instead of jaws, with which it appears to scrape its food with a backward and forward motion; the last joint of the body is furnished with several tubercles. The chrysalides are about $\frac{1}{4}$ in. long, oval, and somewhat flattened, horny, and of a yellowish-brown colour; the joints are very distinctly marked. G. S. S.

Spikenard of the Ancients.—As a writer in your last number (p. 197) revives a confusion which formerly existed, but which seemed to have been conclusively settled, a short statement of the facts bearing upon the question what this perfume was, may be of interest. The plant named by Mr. Wintle, *Andropogon*, is figured in the article by Dr. Royle, in the "Encyclopedia of Biblical Literature," vol. 2, p. 709, and called *A. calamus aromaticus*. He considers it to be the Sweet Cane of Scripture (*Kaneh Bossem*) mentioned in Exod. xxx. 23, Cant. iv. 14, where it is referred to along with Spikenard and other fragrant herbs; also in Jer. vi. 20, and elsewhere. It was, with other spices, directed to be made into an oil of holy ointment, and still yields the fragrant Grass oil of Central India. The plant is a true Grass. The Spikenard of Scripture (*Nardos*) is mentioned under this name in three places—in the Song of Solomon, and also in St. John's and St. Mark's Gospels; and it is described by Dioscorides and other authors, both classical and Arab. By the latter it is described as like the tail of the ermine, and called

"Sumbul Hindee." From having many spikes to one root it came to be called *Nardostachys*, and from the word *stachys* being rendered by the word spike, it has been translated Spikenard. The plant named *Nardostachys Jatamansi* by De Candolle presents a striking resemblance to ermines' tails. It belongs to the Valerianaceæ, and is figured in the "Treasury of Botany." In Dioscorides and in Persian works on *Materia medica*, two other kinds of Nard are mentioned, the Celtic Nard, called *Sumbul Roomi* or Italian in the Persian works, and the Mountain Nard. The former is interesting, because to this day *Valeriana celtica*, which grows on the Styrian mountains, especially on the Judenburg, is exported largely to the East by way of Trieste, as a perfume. The local name is *Speyk*. In ancient times it was shipped from the great Roman port of Aquilegia, once a place of great importance, though now deserted by the sea. This seems to me to indicate that the *Sumbul Roomi* was most likely the plant still exported from Styria. The true Spikenard, however, was the *Nardostachys Jatamansi*.—E. HARVEY, 12, *Riversdale Road, Aigburth, Liverpool.*

ANSWERS TO CORRESPONDENTS.

Indoor Plants for Winter.—I have a small conservatory, 15 ft. by 8 ft., which is warmed with hot-water pipes, and kept at a temperature of from 35° to 40° and upwards during the winter. What plants should I get to keep up a succession of bloom throughout the winter months?—JUNIOR. [*Chrysanthemums* will be useful till Christmas, and these, with a few zonal *Pelargoniums* prepared for winter blooming, early sown Chinese *Primulas* and *Cinerarias*, with a few tree *Carnations* and pots of *Mignonette* will make such a house gay and sweet. The following may also be added or some of them:—*Camellias*, *Spiræa Lindleyana*, *Eupatorium odoratissimum*, *Salvia splendens*, *Abutilon Boule de Neige*, *Habrothamnus elegans*, *Coronilla glauca*; C. g. *variegata*, *Begonia insignis*, *Erica hymenalis*, *E. Wilmoreana*, *E. autumnalis*, *Epacris*, various kinds, *Cytisus racemosus*, *Chorozema varium nanum*, *Richardia aethiopica*, *Valloia purpurea*. On the back wall may be put *Luculia gratissima*, and on the roof *Lapageria rosea*, and *Tropæolums*, with a few Tea-scented *Roses*.—E. H.]

Crickets Grounds.—The soil of our cricket ground is too rich, which makes it play "slow," and it cuts up very much. What should we do with it this back end to make it firmer and play faster? The Grass is also full of broad-leaved Rib Grass; what is the best means of killing it?—RIPON. [Unturf the whole, remove 3 in. of the top soil, then cover the new surface with 2 in. of house ashes or burnt ballast; replace the 3 in. of soil over the ashes or ballast, and re-lay the turf. Taking up and re-laying the turf will improve the quality of it very much and destroy all the Rib Grass. A good dressing of road scrapings laid on dry and evenly, breaking it with a rake from time to time to prevent it from caking, will also improve the turf.—M.]

Lilies for Forcing.—I think of substituting Lilies for the *Ilyacincths* to be forced for the early spring, and I should feel greatly obliged if you would give me any information as to the best sorts to be forced. Dwarf kinds which would subsequently thrive out of doors would be preferred.—COATHAM [The single crowns of Lily of the Valley, each having a flower-spike in it, are the best for very early forcing. They do well potted twelve or eighteen in a pot; a little dry Moss should be placed over the crowns and the pots, which should be set on the hot-water pipes somewhere from which the light is partially excluded. For later forcing clumps are the best. If Lilliums are meant they do not bear much forcing, and will not flower very early. The best sorts are *L. longifolium*, *L. eximium*, *L. speciosum*, and *L. speciosum album*.—J. O'B.]

Wireworms.—Last autumn I dug up some old Grass land for garden-ground and it is now swarming with wireworms which destroy the crops. Will any of your correspondents be good enough to advise me how to eradicate them, or will they disappear gradually as the turf becomes rotten?—E. J. [If the plot of land is not large the wireworms might be eradicated by sinking slices of Carrot at short distances apart just under the surface, examining them every morning and killing the worms. Salt, lime, and soot are all useful in making the situation distasteful to them. In farm culture wireworms have either been destroyed or banished by sowing a crop distasteful to them, such as Mustard. Frequently stirring the ground and allowing a brood of ducks to have the run of it will destroy many. The pressure of a heavy roller on the land when the cropping will permit of it will be useful; and, lastly, a season's fallow, with cleanly culture if the case is a bad one, will eradicate them.—E. H.]

Yew Hedges.—We have about our gardens a large number of Yew hedges which are about 4 ft. high and 2 ft. wide, cut flat on the top. The last year or two they have been dying at the bottom and getting very weak in places. Some of our friends tell us this is in consequence of the tops not being cut with a roof. Is that the case, or are there any other measures that could be taken to cure them?—W. [Hedges cut in the way mentioned often die off at the base from want of light and moisture. The best shape for such hedges is that of an inverted Y, A thus; and the best thing you can do is to have your Yew hedges cut into that shape next spring, just before growth begins. If thick shoots have to be severed you need have no fear of their throwing out plenty of young shoots to make a well-furnished hedge again.—E. H.]

Carnations and Picotees.—W. S. C.—The blooms sent are all good border flowers; four of them are well worth perpetuating; 4 is very striking, the bright rosy-crimson flakes on a brownish ground colour are quite novel; 6 is of the same type, but the few crimson bars which it possesses are not so striking as the flakes on the other; 5 is a beautiful rosy-crimson self; 2 is a yellow ground Picotee, with rosy-red edge. All of them are somewhat deficient as regards symmetry, and the edges of the petals are serrated, not smooth as they ought to be. The white ground Picotee and self Carnation are not worth propagating.

Names of Plants.—O—1, *Liatris spicata*; 2, *Sedum reflexum*; 3, *Spiræa sorbifolia*; 4, *Sedum dasycarpum*. J. M.—*Centaurea Jacea*. R—*Liatris spicata*. J. T. F.—*Clarkia pulchella* (red and white flowered varieties). H. W.—1, *Deutzia scabra* fl.-pl.; 2, *Campanula persicifolia* fl.-pl.; 3, *Jasminum officinale*; 4, *Lonicera Periclymenum*; 5, *Fuchsia virgata*. W. C.—*Lycium barbarum*. M. T. F.—1, *Lythrum Salicaria*; 2, *Liatris spicata*; 3, *Lobelia cardinalis*; 4, Cut-leaved Bramble (*Rubus fruticosus* var. *laciniatus*). Dorset.—*Passiflora racemosa*. A. B.—1, *Adiantum amabile*; 2, *Asplenium flaccidum*; 3, apparently a frond of *Dicksonia antarctica*. J. B. R.—*Pyrus Sorbus*. J. H. E.—1, Next week; 2, *Doodia dives*; 3, *Nephrodium molle*. *Omeqa*.—*Santolina incana*. S. M.—1, *Polygonum cuspidatum*; 2, *Adiantum Capillus-Veneris*; 3, *Impatiens glandulifera*. Devon.—1, *Polydium Phegopteris*; 2, *Asplenium Trichomanes*; 3, *A. monanthemum*; 4, *Alydium Filix-femina*, var:

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

NOTES OF THE WEEK.

Lælia Sedeni.—A unique example of this lovely Orchid is now finely in flower in Messrs. Veitch & Son's nursery at Chelsea. It is a hybrid raised by Mr. Seden, the result of a cross between the little known *Lælia devoniensis* and *Cattleya superba*. It partakes somewhat of the character of the latter parent in habit of growth, but the flowers are rather larger than those of that species. In colour they are a rich deep lilac, the lower part of the lip, which is about 1 in. across, being beautifully crisped on the margin and of a brilliant deep purple hue, while the upper portion is pure white, shading off to rosy-lilac. The whole flower exhibits a richness of colour quite unsurpassed by any kind of Orchid, and when less rare it will undoubtedly be much prized in collections. In the same house the charming little *Phalaenopsis Esmeralda* is bearing over a dozen flowers on each spike. They are about 1 in. across and of a pleasing rosy-purple hue.

Gentiana affinis.—This new species of Gentian is now in flower in Mr. Ware's nursery at Tottenham. In habit it is in the way of *G. septemfida*; it grows about 1 ft. high, and has leaves varying in form from narrow lance-shaped to ovate oblong. The flowers are numerous produced in a thyrsoid manner nearly the whole length of the stem, and are interspersed with the leaves. They are from 1 in. to 1½ in. in length, with the corolla lobes, which are rather short, spreading horizontally. Their colour is a bright deep blue, scarcely inferior to that of the lovely Bavarian Gentian (*G. bavaria*). It is apparently a vigorous grower, and is perfectly hardy. It is a native of California, where it is found at an elevation of about 5000 ft. on the north-eastern portions of the Sierra Nevada. It also inhabits the Rocky Mountains and British Columbia.

Arnebia echioides.—As a proof of the value of this handsome and very rare Boraginaceous plant as a hardy border flower, it is worth noting that the plant on the rockery at Kew has produced a continuous crop of flowers since the spring, and that at the present time it is even more attractive than earlier in the season. It succeeds admirably in the open border at Kew, and will doubtless be perfectly hardy even in an ordinary border. The singular tendency of the deep brown spots on the bright yellow to fade and become finally obliterated was alluded to in the letterpress that accompanied the engraving given of the plant at p. 409 of THE GARDEN.

Veronica longifolia subsessilis.—This is without doubt the finest of all the hardy herbaceous Speedwells in cultivation. From the well-known Long-leaved Speedwell (*V. longifolia*) and its numerous varieties it differs as regards its more robust habit and broader and shorter leaves, which are almost stalkless, hence its specific name. The flower-spike, too, is much larger, as are also the individual flowers, the colour of which is a brilliant deep amethystine blue, a colour which contrasts strikingly with the rich green foliage. It is a Japanese plant, introduced recently by Mr. Ware, of Tottenham, in whose nursery it is at the present time one of the most attractive objects in the whole collection of hardy plants. A poor representation of it as regards colour was given in the January number of the "Botanical Magazine" of the present year.

New Allium (A. karataviense).—The current number of the "Botanical Magazine" contains an illustration of this new hardy plant, which has been recently discovered in Central Asia, where it inhabits the Karatau and Alatau mountains. As a garden plant it will not be of great value, as the flowers much resemble those of the common *A. nigrum*, but it is apparently considerably dwarfer than that kind. Its chief attraction, however, is not alluded to in the description accompanying the plate, viz., the beautiful appearance of its broad leaves early in spring. They are at that time a rich deep green, which is overlaid with a glaucous hue, and a conspicuous margin, 16th-in. wide, of a bright brick-red tint.

New Zealand Flax in Bloom.—One of my plants of *Phormium tenax* is in bloom. Its leaves are 7 ft. long; stalk or scape 11 ft. high and 6½ in. in circumference. At thirteen of its joints are bunches of from twenty to thirty flowers. It is about seven years old. I fancy this is an unusual height, as I saw one at that favoured spot—Falmouth—a year or two ago not more than about half that height. It was in the aristocratic society of *Chamerops Fortunei* and *Dracæna australis*, both of which were also in bloom.—J. M. CHARMOUTH, *Dorset*.

Trillium nivale.—This, though one of the smallest of all the Trilliums, is nevertheless well worth a place in a collection of plants. Apart from its size, it is an exact counterpart of its handsome congener *T. grandiflorum*, having pure white blossoms of similar form, and produced in much the same manner. For growing in peaty soil in the choicer and partially shaded parts of the rock garden, or in similar situations in company with other Alpines, it is a welcome addition. It inhabits woods in the North-western States of North America. It is well represented in the present number of the "Botanical Magazine."

Moggridge's Fritillary (Fritillaria Moggridgei).—Lovers of hardy bulbous plants will be pleased to learn that this beautiful Fritillary has been successfully introduced in quantity by Messrs. Backhouse, of York, who are now distributing it. Mr. Baker, in his monograph of the Order, ranks it as a variety of *F. delphinensis*, from which it differs in having a dwarfier habit, broader foliage, and yellow flowers. It is a native of the Maritime Alps, where, during the flowering season, it is said to give the slopes on which it grows the appearance of a sheet of gold. It is one of the numerous discoveries of the late Mr. Moggridge, in whose work ("Contributions to the Flora of Mentone") it is well figured.

Digraphis arundinacea variegata—Humea elegans.—A circular bed of these plants on the lawn at Pendell Court is now the admiration of every one who sees it. If not a novel arrangement it is by no means a common one, and is certainly deserving of imitation. The Grass forms a belt about 2 ft. high round the group of *Humea*, the plants of which have reached from 6ft. to 7ft. in height. The elegant, reddish-brown, feathery inflorescence of the latter contrasts finely with the silvery variegation of the Grass, and forms a most effective mass, which is moreover of a permanent character from spring till autumn. The *Humeas* require to be grown the previous year, and treated liberally, in order to form large plants by the following spring. The Grass being a hardy perennial does not require removal in autumn.

Cyananthus incanus.—The seed of this plant, introduced by me some two years ago, produced two varieties, one of which was superior in size of flower and intensity of colour to the other; the last form has been blooming freely recently in Mr. Riches' nursery at Tooting. I think the plant is still scarce and very little known, but when once seen it must become a favourite wherever *Alpine* plants are grown, its pendent habit and lovely porcelain blue flowers being so thoroughly distinct and beautiful.—W. H. GOWER.

A Pigmy Spiræa (S. cæspitosa).—One of the smallest, if not the smallest, of *Spiræas* is this singular Alpine species, which we observed on the rockery in Mr. Joad's garden at Wimbledon. The leaves, which are from ½ in. to 1 in. long, narrowly spoon-shaped, and silky and glaucous on both surfaces, are arranged in dense rosette-like tufts springing from a woody root-stock; they are numerous produced, and form a spreading carpet-like tuft, similar to the Stemless Catchfly (*Silene acaulis*). The flowers are from 1 in. to 3 in. high, terminated by a dense cone-like spike of flowers, which are very small and white. It is a native of the mountains of North America, from New Mexico to Northern Nevada, where it is found growing on rocks, &c.

Argemone hispida.—This handsome new Papaveraceous plant may now be seen in the Kew collection. In general appearance it much resembles the Mexican Poppy (*A. mexicana*), but the flowers are pure white and have a pretty appearance when fully expanded, as they measure from 3 in. to 4 in. across. It is a native of Colorado, from whence it was introduced to Kew about two years ago.

French Gladioli.—We have received from Messrs. Vilmorin, Andrieux, & Co., of Paris, some magnificent varieties of this gorgeous autumn flower. Amongst new varieties are Baroness Burdett Coutts, a kind with spikes 18 in. long, and bearing unusually large flowers of a rosy-lilac hue, heavily mottled with streaks of a darker shade; Flamingo, with flowers not so large as the last, but of a most brilliant scarlet, with dashes of deep purple on the lower divisions; and Mlle. Marie Nies, a variety which produces dense spikes furnished with flowers of unusual size, fine in form, and in colour rich deep rose, with a white stripe down the centre of each division, the lower segments being almost entirely white. Amongst older kinds the bright scarlet sort called *Le Vésuve* is one of the best, and nothing can be prettier than another of the same colour, but striped and dashed with white, called *Phébus*. Of a darker hue are *African*, also striped and flaked with white, and *Jupiter*, of a blood-red tint, striped and flaked with maroon. Amongst salmon-coloured kinds the best are *Titania*, with large, bold flowers flaked with a whitish tint; *Hesperide*, a beautiful Carnation-striped variety; and *Célimène*, equally handsome, though not so conspicuously marked. Of crimson coloured kinds *Horace Vernet* and *Lulli* are both beautiful varieties; the last the lighter-coloured of the two. The best of the

Carnation-striped, bright rose kinds are Ambroise Verschaffelt, Conquête and Murillo, all more or less striped and flaked with white. L'unique Violet is a large-flowered, bright pink kind, shaded with violet. The nearest approach to white in the collection is Norma, the flowers of which are large, fine in form, and densely arranged on the spike. Another good light kind is Mlle. Desportes; and others of a darker shade, but equally handsome, are Schiller, Carnation, Rosita, Phénix, Eglantine, and Zampa, all varieties of the highest merit; last, but not least, is De Mirabel, a lovely carmine, tinted and flushed with white. Altogether, this is one of the finest collections of Gladioli which we have seen this year, either as regards diversity of colour, size, both of flowers and spikes, or vigorous growth.

Omphalodes Luciliæ with Bright Green Leaves.—This is a distinct form and well worthy of a varietal name, though it differs in no way from the original except that the leaves assume a rich green tint lacking the characteristic glaucous hue. We saw plants of it in flower a few days since in Mr. Parker's nursery at Tooting.

Spreading Harebell (*Campanula patula*).—Two years ago I met with this pretty but scarce Harebell on the banks of the Wye, between Chepstow and Monmouth, and brought some seed home with me. This summer it has flowered beautifully, and I have not a prettier plant in my garden or greenhouse. Two or three plants in 6-in. pots have been the admiration of our friends and neighbours. I will send seed of it as soon as it is ripe to any correspondent who may wish for it.—H. BURNEY, *Wauendon Rectory, Woburn, Beds.*

Hypericum Coris.—This is evidently confused in some collections with *H. empetrifolium*, which, though somewhat like it, is quite a distinct plant. The true *H. Coris* has slender branches having a tendency to trail, and is furnished with small narrow foliage having a glaucous hue. *H. empetrifolium* is an erect-growing kind, with bright green leaves with no trace of any glaucous tint. Both bear clusters of small yellow flowers and bloom about the same time. They are now in flower in Mr. Parker's nursery at Tooting.

Hyacinthus candicans.—A plant of this 5 ft. in height, and bearing twelve fully expanded flowers, and above them a spike of plump fresh buds and bracts, may now be seen in the College Botanic Garden, Dublin. It is lovely, each flower being of tuberoselike whiteness, nearly equal in size and purity to the white *Lapageria*, and moreover delicately fragrant. If it ever be possible to obtain clumps of it what a glorious contrast it will make with *Tritoma Uvaria* and *Agapanthus umbellatus*! Those who have not this fine hardy species should immediately note it down as a superb plant.—B.

Alocasia scabriuscula.—In our note on this handsome new Aroid given at p. 216, it was inadvertently stated to be an *Anthurium*. We are also informed by Mr. Brown, of the Kew Herbarium, that it was one of the discoveries of Mr. Burbidge in north-west Borneo when on his recent expedition for Messrs. Veitch.

Single-flowered Dahlias.—Conspicuous amongst the rich collection of hardy plants in Mr. Joad's garden at Wimbledon, are some fine examples of the original species of Dahlias which have recently become popular. They certainly rank amongst the brightest of outdoor flowers at this season, and are scarcely less showy than the florists' Dahlias, which have now become almost perfect as regards size and form. The species which the single-flowered kinds apparently represent are *D. coccinea*, *D. Cervantesi* (the former with bright red, the latter with orange-scarlet blossoms), and *D. variabilis*, the flowers of which vary from the rich hue of the variety Paragon to bright yellow and pure white. All the flowers of these have large yellow centres, which form a striking contrast to the bright hues of the ray florets. The neat little *D. glabrata*, with its pretty mauve tinted blossoms, should also be included, for though the flowers are rather small they are borne in such profusion as to fully compensate for this defect.

Hardy Autumn Flowers at Tooting.—One of the most effective displays of hardy plants now to be seen in flower in the neighbourhood of London is in Mr. Parker's nursery, which is, in fact, the only place in which we have seen hardy flowers arranged in quantity with regard to effect. The late summer flowering kinds are now at their best, and, notwithstanding the exceptionally unfavourable season which we have had, they seem to have thriven admirably. The plants are disposed in lines which run at right angles to the shrubbery skirting the road, and the colours are arranged so as to harmonise with each other. The most noteworthy bed consists of a central row of the Flame Flower (*Kniphofia Uvaria*), on either side of which is a belt of *Echinops ruthenicus*, with globular heads of flowers of a bright amethyst tint. This bed has an edging of Ribbon Grass (*Digraphis arundinacea variegata*), and forms a most attractive feature. Another bed is composed of the bright yellow

Rudbeckia Newmanni, with broad belts on each side of the beautiful white *Hydrangea paniculata grandiflora* intermixed with a blue *Aconite*. *Harpalum rigidum*, edged with *Yucca flaccida* and *Aster Amellus*, forms another attractive bed, and near it is a mixture of scarlet *Gladioli* and light blue Larkspurs, which form a beautiful contrast. Golden and variegated leaved shrubs used for similar purposes answer capably. Only the finest of hardy flowers are used for the purpose, and the arrangement admirably exemplifies the effect which can be produced by such material alone, whilst it affords a striking contrast to the meagre appearance of ordinary tender bedding plants in such unfavourable seasons as the present. It is a matter of surprise that bedding with the finest hardy flowers is not more generally practised, for no class of tender plants can produce the same variety of colour and brilliancy as may be found amongst hardy perennials.

Lilies and Disa grandiflora at Glasnevin.—For the last few days we have been having a very severe storm, which is doing great harm to vegetation and injuring the crops. Our Lilies have suffered much this year, many only just setting their buds and then rotting away. *L. chalcedonicum*, *L. carolinianum*, *L. Browni*, and *L. puberulum* have especially suffered, while *L. candidum*, *L. giganteum*, and all the section with strong large leaves have done very well. *Disa grandiflora* was never better. We have at least fifty pots of it at present in flower, and, though past their best, they are still very beautiful. From five to nine blooms on the largest spikes is a sight not often seen, the individual blooms being large in proportion to the number, and very highly coloured.—F. W. MOORE.

The Fringed Pennisetum (*P. fimbriatum*).—This is one of the most elegant Grasses with which we are acquainted. It grows from 1 ft. to 1½ ft. high; the flower-spikes being borne on slender stems. The spikes are from 4 in. to 6 in. long, and have a singularly twisted appearance. The spikelets comprise from two to four flowers, furnished with long hair-like awns, and the whole of the spikelets are enveloped in a feathery down of a purplish colour, which is of a deeper hue when young. We saw it a few days ago in Mr. Stevens's garden, at Byfleet, mixed with other hardy border flowers. It is admirably adapted for cutting purposes, as it lasts such a long time in perfection. Unlike most of the ornamental Grasses, it is of perennial duration and perfectly hardy.

Himalayan Cyrtandraceæ.—The first of these interesting plants, distributed from Kew last year, which we have seen in flower is in Mr. Joad's garden at Wimbledon. This plant much resembles some of the species of *Chirita*. The plants, of course, are not yet fully developed, being only about 6 in. high, with ovate pointed leaves, which are bright green mottled with a darker shade, and covered with short dense hairs on both surfaces. The flowers are produced from the axils of the leaves on stalks a few inches long, and are the shape of a *Gloxinia*, about 1½ in. long; inside they are of a delicate mauve, with two conspicuous yellow stripes in the throat; outside the tube is of a much lighter hue. It is altogether a pretty plant, the value of which in a decorative point of view will be considerably enhanced if it will withstand such a low temperature in this climate as it is thought it should do, seeing that it inhabits such high elevations on the Himalayas, where oftentimes severe cold prevails.

Hæmanthus carneus is the name of a neat little species now in Mr. Elwes' collection. Though an old introduction, it is worthy of a place in every garden on account of its pleasing colour, which is a rose-lilac.

Salvia farinacea.—In Mr. Joad's garden at Wimbledon are houses devoted entirely to such half-hardy subjects as this, planted out in borders, and under such conditions they attain almost native luxuriance. Amongst his collection of the handsome half-hardy *Salvia*, *S. farinacea*, the beautiful Mexican species figured in THE GARDEN (p. 430, Vol. IX.) is now a very attractive object, as it is bearing abundantly, its long spikes of lavender and white flowers being very pretty. *S. cacaliæfolia*, with its beautiful sky-blue flowers similar to *S. patens*, is also a showy and desirable sort, as well as the crimson-flowered *S. porphyranthera*, both tender kinds which make capital greenhouse plants.

Imported Phalænopsids.—A fine importation of the lovely Moth Orchids (*Phalænopsis amabilis* and *P. Schilleriana*), consisting of nearly 2000 plants, has recently been received by Messrs. Veitch & Sons, Chelsea, in excellent condition, scarcely a leaf being in any way injured. This circumstance affords a vivid illustration of the improved mode of transmitting choice exotics from the Tropics compared with what collectors and introducers had to contend with years ago. It is interesting to observe in this consignment the unusually long and narrow leaves which the plants develop in their native habitat compared with what they produce under artificial culture.

THE FLOWER GARDEN.

PLANTS IN FLOWER AT READING.

Stocks.—In a season like the present, when most kinds of summer-bedding plants are failures as regards the production of masses of colour, it was a positive surprise to see at Messrs. Sutton's the other day richly-coloured beds of Stocks finely in bloom. They comprised the old-fashioned Ten-week, the Giant Ten-week, the Pyramidal, and other sections, all of which are well described as annual or summer Stocks. For the production of masses of colour, for pot culture, or for ordinary border decoration, the chief place must be given to the neat, compact, yet massive Pyramidal kinds. In colour there is enough of variety amongst these to satisfy every one, and some colours, such as the bronze, brick-red, and similar hues may be dispensed with. Of these pyramidal kinds there are the glossy green, wall-leaved, and woolly rough-leaved sections, but as regards habit and general usefulness there is little difference among them. The most pleasing colours are pure white, creamy white tending to yellow, white suffused with peach, pink-white, puce, cherry-red, carmine-red, brilliant scarlet, purple, violet-purple, and crimson; to these it is possible to add several others just as taste may dictate; but the colours specially mentioned are sufficient to indicate the various rich tints that can be employed to produce effective masses. The Pyramidal Stock grows to a height of about 10 in., has a centre spike around which the side shoots or spikes are grouped in regular form, and is throughout remarkable not only for evenness of habit but also for the production of about 80 per cent. of double flowers. If beds of these beautiful Stocks in distinct colours were but submitted to the inspection of the frequenters of our public parks and gardens in summer instead of the repetition of scarlet, white, and blue bedding plants so common, how greatly would they be appreciated by lovers of really beautiful flowers. These Stocks are liberally treated at Reading, but they do not need richer soil than is provided for ordinary bedding plants.

Phlox Drummondii.—Other charming plants were the dwarf forms of Phlox Drummondii—forms producing singularly neat, compact, dense bunches of flowers and foliage, and offering all that can be desired as dwarf plants for the production of masses of colour. The name given to a dark rich red kind, Phlox Drummondii nana compacta coccinea, is simply discouraging; but these designations are chiefly manufactured on the Continent, and bother seedsmen as much as they do the public. This is, however, a most beautiful variety, the colour of which is rich and striking, and the habit of the plant dense and perfect. Others are Fireball, crimson-red; rubra, deep rosy-red; and cardinalis Heynholdii, fashionable cardinal-red; a singularly pleasing hue is seen in a sort called the Rose Chamois, the colour of which is a charming salmon-rose, with a deep carmine red centre; this is a very dwarf and free kind. All these plants have been raised under glass, pricked off into small pots, and after exposure in cold frames, turned out into the open ground. Close by are also in great variety all the forms of the tall, large-flowered section of P. Drummondii, but these want a good deal of pegging down, and sadly lack habit and effect as compared with the dwarf forms.

Petunias.—These, raised from seed, of all forms and colours are just now very beautiful in the open ground, although, being subject to frequent rains, they show too much tendency to growth. The shapes of the flowers, their colours, and markings are very varied and fraught with the greatest interest; they produce grand masses of colour and make some of the most effective of bedding plants.

Lilium longiflorum.—This pure white large-flowered Lily, grown in great masses, is just now magnificent. The bulbs are planted thickly in rows, and every one is producing flowers with remarkable evenness at a height of about 20 in. No white flower could excel this for distinctness and beauty, and as garden features these beds are for the time unrivalled. The season has suited these Lilies exactly, and the masses thus seen indicate in what way this Lily might be employed to produce striking effects.

Gloxinias and Begonias.—Indoors, Gloxinias are beautiful, all the plants—and there are many hundreds—being the produce of Messrs. Sutton's own seed. Those of the present year's sowing, and, of course, saved from the last year's stock, show a marked advance in quality, and indicate how well the work of selection has been done. The fine rigid erect flowers predominate: they are very large and perfect in form and most varied in colour, with a tendency in many to show deep rich reds, blues, and maroon-purples that are none too common amongst Gloxinias. The plants raised from seed sown in January and February last, now blooming in 4½-in. pots, show what can be done in six months in the production of these beautiful flowers. This batch will bloom freely for the next two months if given now and then weak manure-water. The Begonias

are very fine, rich-coloured, and varied, and are a brilliant feature, just now rather past its best, but indicating a grand strain. These are but a few prominent matters in a place singularly full of interest at this time of the year.
A. D.

THE BROAD-LEAVED BELLFLOWER

(CAMPANULA LATIFOLIA).

THIS, one of the handsomest of the Bellflowers, often attains in good soils a height of 6 ft., and fully a third of the stem is furnished with long bell-like flowers, which droop gracefully and are of a violet-purple tint. The Nettle-leaved Bellflower (*C. urticæfolia*), of which there are blue and white flowered varieties, and also a form with double flowers; *C. Trachelium*, a vigorous growing kind, with coarsely toothed leaves; the Milk-flowered kind (*C. lactiflora*), which forms a pyramid of blossom 4 ft. high; and the Pyramidal Bellflower (*C. pyramidalis*), are amongst the largest of the commoner kinds. The Long-flowered Bellflower (*C. nobilis*), too, grows quite a yard high in some gardens, and is one which should be grown in every collection, as it has large-sized blossoms, blue in the type and creamy-white in the variety alba. *C. Van Houttei* is another handsome kind, though but slightly different from the preceding. All the large-growing kinds will thrive anywhere in ordinary soil, and

The Broad-leaved Bellflower.

are capital subjects for planting on the margins of shrubberies, woods, and walks, and even in the wild garden, as they take care of themselves, and spring up annually from self-sown seeds.—W. G.

FLOWER GARDENING IN HYDE PARK.

THE fine weather which we have had during the past week or two has helped considerably to brighten up the bedding display in this park; but the wet and sunless season has, nevertheless, left indelible traces in the shape of lank weedy growth and paucity of blossom on the majority of the flowering plants, such as Pelargoniums, Calceolarias, and Lobelias. The advantages of carpet bedding over that of flowering plants for producing a bright effect in wet seasons are vividly exemplified here and elsewhere this year, for since the first week in which they were planted the carpet beds have been very effective, and seem to be quite independent of the weather, except that in some cases the more tender kinds have not grown sufficiently to make the pattern or design clearly defined. This style of bedding is carried out on an extensive scale in the line of beds adjoining Park Lane. A noteworthy feature regarding the carpet beds here is the variety of plants brought into requisition, many of which are not generally employed in the other parks. Amongst these are the pretty little *Achillea umbellata* with its hoary pectinate leaves, the Alpine *Hutchinsia* (*H. alpina*), a capital plant in exposed situations, and one which forms a deep green groundwork; various kinds of Saxifrages both of the crustaceous and other sections; numerous kinds of Stoncrop, and many other plants, all of which tend considerably to relieve the monotony of employing the same kinds over and over again in equally monotonous designs. A pair of circular beds opposite the Mount Street entrance are particularly attractive, both the

designs and the plants with which they are filled producing a pretty effect. A large bed of a similar shape on the lawn which skirts the Row is also extremely pretty, all the plants used for the groundwork having done well, as have also numerous plants of elegant habit which are dotted about with capital effect. The patterns of the other beds are, on the whole, equally neat and attractive, presenting as they do a well-kept and trim appearance. An objectionable feature, however—one wholly due to the unfavourable weather—is the half-grown and partially-rotted plants of Succulents dotted here and there in the beds, which are otherwise as flat as a carpet. Graceful plants in such positions would present an elegant appearance; but these (which by no means represent the true characters of the plants) produce quite an opposite effect. Another defect is the long line of beds beneath the shade of the trees which skirt the fence, a position in which even turf itself refuses to thrive as it should do. These are filled chiefly with Pelargoniums of various sorts edged with Lobelias. The flower beds in other parts of the park are much the same as regards arrangement as in former seasons; therefore comment on these is unnecessary. Novelties in the way of bedding plants are scarce apparently, for few are noticeable. This is, however, the less to be regretted as the abundant resources of such plants as are of well-tried merit leave but little room for new comers.

The sub-tropical bedding presents about the usual appearance, except that the annual fine-foliaged plants, such as Tobacco, the Castor Oil, Maize, Wigandia, &c., have not attained half their usual dimensions, a circumstance which has considerably marred the effect they would have otherwise produced. The sheltered enclosure at the head of the Serpentine known as the "Dell" is very tastefully planted with bold and handsome sub-tropical plants. The tall Cordylines rising above the dense undergrowth of shrubs have a picturesque appearance. Bananas, Tree Ferns, Aroids, and similar plants, are also effectively dotted about here and there; those on the lawn, however, appear to be grouped in too equi-distant a manner, and therefore do not look so well as they would have done if grouped with less precision as to distance.

The margins of the stream which flows through this beautiful glade present a very pretty effect, being fringed with Ivy, clumps of the Royal Fern (*Osmunda regalis*), *Elymus giganteus*, *Glyceria aquatica*, and other plants, which flourish in native vigour. There are many other plants, too, that could be introduced here with advantage, and which would afford greater variety. Amongst these may be mentioned the noble *Gunnera manicata* and *G. scabra*, *Ariundo Donax* and its variegated-leaved form, *Saxifraga peltata*, which attains grand dimensions in a moist situation; *Thalia dealbata*, a semi-hardy, Cannalike plant; *Senecio japonica* (*Erythrochæte palmatifida*), *Richardias*, *Sagittarias*, *Typhas*, and others equally beautiful. Two large circular beds on the lawn adjoining the Row planted with the Coral Plant (*Erythrina Crista-galli*) are now the admiration of every one, as every branch forms a perfect wreath of blood-red blossoms. The legible labelling of all the plants in the beds in this park is a very commendable feature, and one that should be imitated in the other public parks, as it not only enhances the interest of the collection, but also aids those who wish to take the names of desirable kinds which they may wish to introduce into their own gardens.

W. G.

AURICULA GOSSIP.

I HAVE much pleasure in replying to Mr. Horner's enquiry (p. 213). Our Auriculas were repotted the second week in June. We have about 250 plants, in all eighty-three sorts, without reckoning Alpines. Of these eleven have shown for bloom, viz., of green edges—one Booth's Freedom, two General Niel, two Ne Plus Ultra, and one Lady Richardson; of white edges—one Wood's Delight, one Countess of Wilton, and two Maggie Lander; and of selfs only one Lord of Lorne. Of these, three did not flower in the spring. Unfortunately our best plant of Freedom is amongst the above, but it has so strong a crown that I feel sure it will flower again in the spring; and for the rest I care very little; indeed, I believe its not flowering is in the blood (or sap), as both General Niel and Ne Plus Ultra served us the same last year. Of the more valuable sorts I have eight George Lightbodies, six Lancashire Heroes, and three Smiling Beauties, all looking comfortably fat and well for the winter. I judge therefore that my little flock are all right with their late potting; and that although the percentage is higher than Mr. Horner's, it is more influenced by a preponderance of erratic sorts than by ordinary circumstances.

On reading the melancholy record of the results of Mr. Douglas's experience with his early potting I exclaimed: "We told him so. What will Mr. Horner say now!" And Mr. Horner says now, that he is still in favour of early potting. And when he and Mr. Douglas say so—our two greatest growers and authorities—small men must be quiet. Nevertheless, I find our Lancashire florists against them. Mr. Barlow had not repotted a plant of his when I visited Stakehill

early in July, and I know many other florists who pot their Auriculas much later than Mr. Douglas advises. I feel convinced that it is best to let the plants grow on awhile after flowering, leaving them to complete their maturing; and then, when they are at rest, repot them and let them rest on for the winter. It appears to me that early potting encourages a double growth every year. It is possible enough, with care and loving patience, for an enthusiast like Mr. Horner to watch and nurse them so carefully that, in his northern regions, they will sleep on and behave themselves discreetly; but in the warmer climate of Loxford Hall it is clearly beyond the power of Mr. Douglas to keep them back, and they flower afresh in spite of him. Small growers like myself have not the plants to spare for extra risk, and there is safety in the medium course, so I say now, pot early in June, and not earlier.

Mr. Horner stated (vol. xv., p. 402) that his usual average of autumn bloom was from two to five per cent. I should suppose therefore that the cold and wet summer would account for his present very low average of one per cent. I may add that my Auriculas have not been placed under a north wall this year, but kept in frames in an open situation. Any little sunshine there has been has done them good. Indeed, I do not believe in the north wall theory, except in very hot summers, and it is possible that the great mortality which has been noted this year in Auriculas may have its root in this overshadowing them in damp dull weather.

BROCKHURST.

REMINISCENCES OF THE PRIMROSE.

THE double yellow Primrose was probably as plentiful fifty years ago as it is now. I remember forming lines of it by the sides of paths in cottagers' gardens as far back as 1823 in the same way as double Daisies were subsequently used, but strange to say it has ceased to be met with so abundantly as at that time. For some years it was the most extensively cultivated of the family, unless we include the Polyanthus, which was perhaps as plentiful and in some cases as good as at the present day, and most certainly Auriculas were more healthy at that time than now; but the Primrose which the enterprising young gardener sought after at that time was that imperfectly-known British species *Primula farinosa*, and the localities in which this singular member of the family was to be met with occasioned many a long journey. It was not to be met with everywhere, and I do not remember even seeing it in a cultivated form; but as years passed on other members of the *Primula* family were brought into notice, the Chinese species attracting much attention, while I think double forms of the hardy mauve and white were in cultivation before the single ones of the same colour, and a great advance was made in *P. cortusoides*, which was introduced about 1840, when other forms of the hardy Primrose were becoming more common, and I may here remark that there have from very early times been two, if not more, varieties each of the double yellow, mauve, and white, one of them being more robust than the others. I mention this here as I never saw a claim to one of the strong-growing ones having a recent origin. Years rolled on, and new varieties made their appearance; but for many years I lost sight entirely of the old double yellow, and about 1865 I visited an out-of-the-way village in a far-off county, where I had seen it so plentiful about forty years before, and found it had almost, if not entirely, disappeared there; certainly it was summer time when I was there, so I could not obtain a single plant. Subsequently, however, I obtained a tolerably good variety of that colour from a friend who had picked it up in a wood where it was discovered by one of the men employed in the Ordnance Survey, and doubtless the original one had been obtained promiscuously in the same way. I regret the advent of the Japan species has not resulted in some useful hybrids; but it is not too late to hope for some yet, for assuredly something good must follow this accession to the family. But there seems a certain amount of waywardness in the family, and what little I have done in the way of raising new garden varieties has been generally done by letting the kinds I desire to save seed from hybridise themselves by planting them together, and in a position where they might seed and sow themselves. I may further add that I have in my time endeavoured to disseminate the garden varieties amongst our wild ones in woods and wastes, and have sown Polyanthus seed, &c., in quantity where I expect in some one's time it will make a mark.

AN OLD GARDENER.

Gunnera scabra.—This is sometimes said to require a well-drained, warm soil and abundant waterings while growing; here it is planted quite close to the water. Its roots are below it, and thus situated it has withstood the winter, with the protection of a small heap of leaves over its crown, and it is now in the most vigorous condition possible and very effective.—T. SMITH, *Newry*.

THE SPIKENARD OF THE ANCIENTS.

ENOUGH has been written about this plant to fill a good-sized book. All the research and knowledge of some of our most eminent botanists have been employed to set this matter right, and I think if we consider the bulk of the evidence, we must feel satisfied that *Nardostachys Jatamansi* is the true Spikenard of Scripture, and not *Nardus indica* as stated by Mr. Wintle (p. 197). A special study of this plant was made by Sir William Jones, President of the Royal Asiatic Society, who discovered that the veritable Spikenard of Scripture was a species of Valerian, called by the Hindoos *Jatamansi*, signifying a "lock of hair," and he named it *Valeriana Jatamansi*, now recognised by modern botanists as *Nardostachys Jatamansi*. Any one wishing for further particulars respecting the history of this plant cannot do better than read Sir William Jones's papers in "Asiatic Researches," also those of Dr. Roxburgh and Dr. Royle, both of whom contributed to the same work. After reading these papers I think every one must come to the conclusion that the *Nardus* of Ptolemy, the Indian Sumbul of the Persians and Arabs, the *Jatamansi* of the Hindoos, and the Spikenard of the shops in Calcutta, are one and the same plant. Dr. Patrick Russel was also convinced that the Indian Nard of the ancients and that sold in the shops in Calcutta are one and the same plant. The plant of which the annexed is

The Spikenard of the Ancients (*Nardostachys Jatamansi*).
Half natural size; colour of flowers purple.

an illustration was raised at Mr. Ware's, at Tottenham, early in the spring of 1878, from seed obtained from Northern India. The young plants thus raised were potted and stood out unprotected the whole of the winter; this spring they were planted out on the rockery in a partially shady position, in sandy loam, and they are now about 9 in. in height, and are still throwing up heads of bloom, the individual flowers in which are small, and of a purplish colour.

A. J. PERRY.

Fuchsias amongst Roses.—April frosts killed for us about ten standard Roses, and we considered it too late to put others in their places. Fortunately we had some good tall well-topped Fuchsias. After hardening them till the first week in June, we turned them out close to the Rose stocks, securing them thereto; thus they not only filled up what would have been ugly gaps, but have vied with the Rose as to quantity of bloom; and, best of all, their flowers have stood the winds and rain perhaps better than any other flowers in our garden. If all is well, we shall use Fuchsias more extensively next season.—JOHN WOOD, *Woodcille, Kirkstall*.

ABRONIA FRAGRANS.

This most beautiful Colorado plant should be known and cultivated by every lover of flowers. It blooms all summer, and is, I think, the most fragrant of all flowers. When in its neighbourhood one is often first made acquainted with its presence by its delicate perfume, which fills the surrounding air. It grows to the height of from 2 ft. to 3 ft.; sometimes upright, but often lying partially upon the ground, or leaning upon other plants or weeds. The branches die to the ground in winter, but the roots are perennial. Its favourite native haunts are rich gravelly banks of streams and ravines; and as we have but little rain during the summer months, it must send its roots down deep into the earth for the necessary moisture to sustain its foliage and flowers during dry seasons. It is called a night-blooming plant: in fact, its flowers only partially close during sunshine, and especially in hot dry weather. I have found them open at mid-day in the shade of trees, and after rain. The flowers that are partially closed by the heat open out an hour or two before sunset, and seem to redouble their fragrance owing to the day's rest. They last well in a cut state, and retain their fragrance for many days. So far as I know no efforts have been made to cultivate it, except that I have attempted, without success, to strike cuttings of it taken from the wild plants. It produces seed sparingly, and can probably be readily grown in that way, as I often see young seedlings in the fields.

Denver, Colorado.

DANIEL WITTER.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Polygonum Sieboldi.—This makes a most excellent water-side plant; growing close to, and even in the water, its beautiful arching stems, now covered with feathery white flowers, are most attractive.—T. SMITH, *Newry*.

Mimulus in Water.—There is a large quantity of *Mimulus* with yellow flowers growing wild in a brook at Boddington corner (Miteham Common). They grow in the water at the edge of the brook like the Forget-me-not, and evidently enjoy the situation. I was not aware before that *Mimulus* were aquatic plants.—C. G., *Addiscombe*. [*M. luteus* is naturalised in boggy places in many parts of Britain.]

Spiræa venusta.—This, planted in a half shady nook among stones, close to the water's edge, has grown over 6 ft. high this season. It has handsome foliage and bears noble heads of flowers, and is altogether superior to *S. palmata*.—T. SMITH, *Newry*.

Ornithogalum aurum.—This has flowered beautifully here this summer. The colour is a remarkably fine rich yellow and the plant lasts a long time in bloom, but its leaves are small and very few in number. I consider it to be a very desirable plant, and one which forms a conspicuous object when in flower.—HENRY BURNEY, *Warendon Rectory, Woburn, Beds*.

Bocconia japonica.—This is said to require a dry, warm soil, but we have a mass of it here in a bed about 3 ft. from the water's edge and only 4 in. above it. Thus situated it has survived the winter, and has grown in the most vigorous manner possible, and strikingly ornamental it is.—T. SMITH, *Newry*.

Aubrietias.—Beautiful as the Forget-me-nots are they have companions equally deserving a place in every garden in the Aubrietias. They are easily grown, very hardy, and last continuously in bloom for a long time. They are useful in mixed borders, on rockwork, and for edging spring beds in the flower garden. Some of the sorts are of free growth and most desirable no doubt, but *A. purpurea* is the kind which is most frequently met with. This, and its handsome companions *A. Campbelli*, *græca superba*, and last, but not least, *A. Hendersoni*, are all useful kinds and distinct; the last has blooms much longer than those of either of the others and much higher coloured. When looking through the gardens at Diddlington Park, Brandon, Norfolk, two years ago last April, I was much pleased to see Aubrietias used as edgings to walks leading to a new maze that had then only recently been made. One side of the walk was edged with *A. purpurea*, the other with *A. græca superba*, and at the time of my visit they were in full bloom, and as the walk had trees on one side and Yews on the other the effect was most pleasing. This and many other spring blooming plants have a good effect when planted in patches here and there in borders about the ornamental grounds in a semi-wild state.—J. C. W. F.

Unseasonable Flowers.—The present season is remarkable for its production of unseasonable flowers. To-day I have three varieties of *Arabis* in bloom. *Polyanthuses* have sent up spikes from the newly-formed crowns. *Primula denticulata* is flowering a second time. Of *Auriculas* we gathered a handful a few days ago, and there are others to-day, and fine flowers too. I had two beds of double-yellow *Primroses* formed in June, and they are now well bloomed, and in a few days will have from three to six on a plant. Several *Androsaces* (*Chamejasme*, *carnea*, *lanuginosa*) have

just been in bloom a second time, and *A. lactea* is now in bloom. also see solitary flowers on *Gentiana acaulis*.—JOHN WOOD, *Woodville, Kirkstall*.

Michauxia campanuloides.—This has proved itself to be a distinct and highly ornamental plant. Here, in a very wet place close to the side of water, it has grown to the height of 6 ft. 8 in., with a clean stem of 3 ft., a point from which the pyramidal candelabra-like crown of white flowers starts. The latter are composed of from six to nine strap-shaped recurved petals about 2 in. long. Standing up above other plants this *Michauxia* is very striking.—T. SMITH, *Newry*.

Bocconia cordata.—This stately Japanese perennial has much to recommend it, though it is not nearly so extensively grown as its merits entitle it. Its large, Fig-like foliage, glaucous beneath, is quite unique amongst hardy plants, and the great vigour and beauty which it attains in deep, warm, sandy loam, in sunny positions, considerably increase its value as a decorative plant. In Mr. Stevens's garden at Byfleet there is a clump of it fully 10 ft. in diameter and nearly 8 ft. high, now finely in flower. Its blossoms, though by no means showy, have a very elegant, feathery appearance, and emit, moreover, a delicious fragrance. It is one of the easiest plants to propagate, either by means of seeds or division; indeed, it is difficult to eradicate it from borders when once it has become well established.—W. G.

Autumn Flowers.—I have a large bed of seedling Antirrhinums in beautiful bloom, rich and varied, and singularly fresh and bright. The plants are of the dwarf or Tom Thumb type, and the growth is even, all the plants being in full bloom at a height of 12 in. Sown in pans under glass early in April, and planted out in June, they have thriven well; and should the winter spare them, will produce a large amount of spikes next summer. It is from old plants such as these would be that the finest exhibition spikes are obtained. Intermediate Stocks also sown early in the spring under glass, furnish a continued display of autumn flowers. To get them into bloom well in the summer the seed should be sown in October under glass, and the plants when large enough should be pricked out singly into small 3-in. pots for the winter. Planted out early in May they will flower richly in July and onwards. The spring-sown plants flower later, and very late if the early winter be open. Pentstemons sown in the spring are equally valuable for late autumn blooming, and if spared by the frost make fine plants the following summer. The beautiful Japan Anemones are just now coming into bloom. These will be glorious all through the autumn, the moist season having suited them exactly. Asters are late, and will give plenty of autumn bloom; indeed, there should be no lack of autumn flowers this season, provided we get no early sharp frosts: but a bad beginning has been made, white frosts having been seen in the Thames valley as early as the morning of the first of September, and the nights altogether are very cold.—A. D.

Begonias at Chiswick.—The seedling Begonias now in flower at Chiswick are well worth inspection, as they present, without doubt, the newest and best amongst this charming and highly decorative class of plants. Richness of colour, robust habit, and erectness of flower-stem have been specially sought for, and these are seen here to have been effected in a marked degree. Here is a quantity of plants raised from seed sown in February, all in 5-in. pots and all in beautiful bloom; this fact shows that it is quite within the power of any one to have a brilliant display from seed by taking similar pains to raise and grow them. There is a decided gain in erect stems; they hold the brittle pendent blooms more fully up to the gaze of the spectator than ordinary forms, and there is a roundness and fulness about the petals which show that the production of grand massive bloom has but just begun; indeed, it would be difficult to prognosticate the future that is open to the Begonia. One thing, at least, is certain, and that is that Begonias will presently rank amongst the most beautiful decorative features of our summer and autumn flower shows. In that respect they will prove a great gain. As bedding plants they want further testing, and the robust kinds seen at Chiswick show increased usefulness in that direction; but, to be seen to the best advantage, they must be planted in a setting of dense greenery and where they are sheltered from fierce winds.—A.

Hardy Primulas.—The season which has been so disastrous to all kinds of tender plants in the open air has been just the reverse as regards all the sections of hardy Primulas. *P. denticulata* and *purpurea* are as fresh and robust as it is possible to conceive, the foliage remarkably vigorous, and the crowns promise to produce grand heads of bloom next spring. Primulas of the *amœna* section have lost their foliage as usual, but show strong, robust crowns and a mass of roots; *P. japonica* has beautiful foliage—indeed, this summer it has been quite a fine-foliaged plant. All kinds of Primroses, Polyanthuses, and Auriculas are fresh and vigorous, and have not lost their foliage materially, or where it has gone the young growth is now

coming up strongly, and the plants will presently have well-furnished crowns. All this points to a fine blooming season for all this family next year, and probably presently a considerable amount of late autumn flowers. Where circumstances will permit, it will be well to get all old stools of Primroses and Polyanthuses broken up this autumn, as it presents a most favourable time for the purpose; it must be done some time, and it will likewise be well to get all others transplanted as early as possible, as that may check the tendency to autumn blooming. All our seeds saved especially for our own sowing of Primroses and Polyanthuses were sown as soon as well ripened, and are now well up under glass and showing the rough leaf. Planted thickly in a couple of months here in good soil and in a sheltered place, many of them will flower next spring. A similar batch raised the previous year are now making fine plants, and will yield good heads of bloom next April. All this section of the Primula family are easily raised from seed, and not one out of a thousand of a good strain will fail to make charming spring flowers.—A. D.

Ellacombe's Yucca.—Mr. Ellacombe, I see (p. 214), says the proper name according to Haworth is *tenuifolia*. I see this is a species named in Sweet's "Hortus Britannicus," but there is no mention of Ellacombei or of Tortulina. At page 356, Vol. IV., of THE GARDEN, Mr. Ellacombe says: "The proper name of Yucca Ellacombei is *Y. tortulata*." Can he now inform us where this name or Tortulina originated? Is it really the variety named by Haworth as *tenuifolia*? If so, it would be advisable that the other names, under which it appears to be more generally known at present, should be done away with, or at least preserved only as synonyms.—ROBERT A. OSBORN, *Fulham*.

Rain-proof Plants.—To the list of weather-proof plants (p. 174), allow me to add the once favourite, but now much neglected, bedding plant *Cuphea platycentra*, commonly called the Cigar Plant. The heavy rains which we have lately experienced only appear to have had the effect of intensifying the rich green of the foliage and imparting additional lustre to the flowers. This plant really seems to enjoy the heavy washings which have proved so inimical to flowering plants generally. Although not so brilliant as many of our summer bedding plants, this *Cuphea* is capable of producing an excellent effect when grown in combination with other free-flowering subjects. The flowers are produced in great profusion, the habit is of the neatest, and the plant retains its beauty unimpaired quite to the end of the season, and may even then be lifted with a ball and stem, and placed in the conservatory, lasting in good condition nearly up to Christmas. Hardy Fuchsias should also receive a word of commendation for their wet-resisting properties. Some of the florists' varieties, such as *Rose of Castile*, also appear to bear without injury a considerable amount of rainy weather. Then we must not forget the Clematis, the beauty of which the most unseasonable weather has not the power to dim. We shall probably not for many years experience a more trying summer than the present for summer flowering plants, and yet I never remember seeing the Clematis in finer condition. I have lately had the opportunity of seeing some fine masses of Jackmanni, rubro-cœrulea, Lucy, Bowei, &c., which, as regards quantity, quality, and freshness of bloom, were simply perfection. Truly the Clematis is a glorious plant for our English climate! so hardy that it requires no care in the winter, demanding but little attention during the growing season, to which recommendations add that of its not being surpassed for effect by any of those summer flowering plants which tax the skill and patience of the grower during the winter months to preserve in health, and I never hesitate to recommend the Clematis to those who desire to beautify their gardens at but little trouble and expense to themselves during the spring and summer months.—J. CORNHILL, *Byfleet*.

An Unusual Phenomenon occurs here as a result of this wet season. In a rook's nest, at the very top of a *Pinus insignis* 65 ft. high, a grain of Oats has vegetated and has produced three stalks, each carrying a head of Oats now nearly ripe, and standing clear against the sky not less than 2 ft. or 3 ft. above the highest part of the tree. The grain was probably carried up by the parent bird to feed the young rooks, together with the worms from an Oat field in the early spring.—J. J. R., *Penrose, Helston*.

Substitute for Box Edgings.—The practice of using the small-leaved Spindle Tree (*Euonymus microphyllus*) as a substitute for Box, as an edging for walks, &c., though perhaps not novel, is certainly deserving of more extended knowledge, as it is even more desirable than Box on account of its greener and neater appearance, and also the greater facility with which it may be kept in order. In Messrs. Lee & Son's nurseries it is extensively used for such a purpose, and with capital results. It is, moreover, perfectly hardy, and does not assume a brown appearance through excessive drought.—W. G.

THE FRUIT GARDEN.

SECURING STRAWBERRY RUNNERS EARLY.

WE are perhaps as unfavourably situated as anybody for getting early crops of any kind, but in the case of securing Strawberry runners early for forcing I do not think we could compete with our neighbours unless we resorted to special measures. Very likely some of your readers who may be situated like myself may long ago have adopted the same means as I am about to recommend; but, as a rule, I believe our plan is not commonly practised. Had we waited during the present season for our Strawberries to form runners before commencing layering operations we should certainly not have had plants fit to pot till nearly September, whereas we were not much later than usual, and had all our stock potted before the end of July, and our 5-in. or 6-in. pots are now well filled with roots, and the plants are of good size, with crown projecting 1 in. above the surface of the pot and as thick as one's finger. In those portions of our Strawberry plots where the runners have been allowed to grow between the rows in the usual way without layering, I find at this date (August 28) that a very small proportion of them have yet got hold of the soil, and in looking over them the other day to get some runners of Vicomtesse Héricart de Thury for a neighbour, plants sufficiently rooted for transplanting could hardly be found. I state this merely to show how late we are and the advantages of the plan adopted to hurry the runners on for potting. It is well known to cultivators that the Strawberry does not put out all its runners at once, but produces them in succession, some being much more advanced than others, and it is the custom to wait till a sufficient quantity is produced before beginning to layer, in order that the work may be completed at one time, as well as an even lot of plants secured; and besides the plan enables one to have all the stock conveniently together. This plan answers perfectly well where runners are produced early enough under any circumstances, but it would not do here. We therefore layer from our forced plants put out early the previous season in good soil, and also from autumn-planted runners that are cropped as well, and from these we select and layer the very earliest runners they produce, not waiting for the runners to show leaves, but pinching beyond the first joint as soon as a joint is visible, and while it is yet destitute of leaves. The point is layered in a good rich compost, and it is surprising how the encouragement thus given promotes the formation of roots and leaves, resulting in plants fit for potting much sooner than they could be secured by the ordinary method. Naturally runners are not disposed to throw out roots before leaves are formed, which in their turn excite root action, but by pinching as soon as a point can be got hold of beyond a joint, and pressing the heel down into the soil, and holding it there with a small stone, both root and top growth are excited at once, and a stout early plant is the consequence. In advocating earliness in the case of runners for forcing, I wish to be understood that I consider from the middle of July till August early enough to pot in 5-in. or 6-in. pots, and when runners can be had fit for potting them by the ordinary method, there is no necessity for resorting to extra measures. Under ordinary good management the pots ought to be crammed with roots before the growing season ends, and the plants should have part of September and all October to mature their growth. The practice of nursing either the runners before they are potted, or afterwards under glass frames, cannot be too severely reprobated. A Strawberry plant for forcing that cannot be grown from beginning to end out-of-doors is not likely to be worth much for any purpose. No one, I am sure, is likely to recommend such a practice who has had much experience in Strawberry culture; still the practice has been advocated, but it is the last shift of the shiftless who neglects his work at the beginning. There is no place I fancy within these islands, unless it be in some unfavourable localities of the far north, where Strawberry plants need the protection of glass at any time before they come to be forced for fruit.

J. S. W.

The Cherry Plum.—I lately saw in the gardens at Burghley a large tree of the Myrobella or Cherry Plum (*Prunus myrobalana*) literally laden with fruit. For the early spring when in blossom as well as at the present time in fruit it is a most ornamental tree. Owing to the early season of the year at which it flowers (as a companion to the Bitter Almond), it does not usually bear a crop of fruit unless, as in the present instance, it is in a sheltered place. We have in the nursery here a large tree of it which flowers generally very freely, but, standing in an exposed position, it has very rarely been known to bear fruit. It may be safely recommended for ornamental plantations, and well deserves a little shelter. Some say that it makes a very good hedge plant.—ROBERT A. OSBORN, *Fulham.*

VINES AND VINE BORDERS.

THIS season will be long remembered for its abundant rainfall and its absence of sunshine; indeed, the one fact always accompanies and hinges upon the other, and it is worth while to enquire what influence such an exceptional season may have had upon Grapes growing under glass. So far as I have seen, where the borders have been well drained, the abundant rain seems to have been an advantage, especially as regards black Grapes ripened from June onwards. Even those Vines carrying very heavy crops have coloured well, and have a denser bloom than usual. In some early houses the Grapes did not colour well, judging at least from the examples I have seen at the different exhibitions, which was probably due to the necessity of hurrying them on with fire-heat, with, perhaps, rather less ventilation than in ordinary seasons. The perfect colouring of Grapes seems to me to be dependent upon the presence of three conditions, which may be briefly stated thus: first, abundant moisture at the roots, but not stagnation; secondly, a buoyant, freely-circulating, constantly-changing atmosphere—and this latter condition implies contact in some way with the atmosphere outside the house; and thirdly, abundant and healthy foliage, to maintain the roots in a constant state of activity. If the main leaves are healthy and plentiful, I fail to see what advantage can be got from the encouragement of much lateral growth; although I know good Grape growers who practise and recommend it after the Grapes begin to colour. But I think fully developed leaves will perform the functions of respiration and assimilation better than imperfect leaves can do. But if the main leaves have been injured, or are deficient in substance or quality, then the lateral growth may be extended with advantage. Sometimes the colouring of black Grapes may be imperfect from too high feeding. Very high living may swell the berries out abnormally, but it plays mischief with the colour. This generally arises from the too liberal use of very strong stimulants, such as guano in a liquid form; the system of the plant becomes overcharged, the berries swelling unequally, often assuming a gouty appearance, and, of course, failing to colour. In such cases a little more freedom of growth to the laterals will be judicious, and will help the colouring immensely if done in time. It acts in the same way as exercise or work does upon an animal or man of plethoric habit—gives a better and healthier tone to the system, and aids Nature in maintaining the necessary balance.

From what has come under my own observation, I think where the borders are well drained there is less shanking, less mildew, and less disease generally, this season. If the conclusions I have drawn are correct, it would seem to strengthen the inference that in dry seasons Vine borders do not get sufficient water. Borders made on a thoroughly drained base will take a deal of water. Look at the quantity of water that may with advantage be given to a Vine growing in a pot, and an artificially constructed border (especially if shallow and circumscribed in its limits) is only an enlarged system of pot culture. When the watering has to be done by manual labour, the chances are against a sufficiency being given in a dry season, either from a misapprehension of the quantity required, or from a lack of force to do the work. Though sunshine, by its action upon the leaves and young wood generally, doubtless does indirectly influence the laying on of colour, yet, in the case of black Grapes, the best-coloured bunches are commonly found in the densest shade. But Muscats and other thick-skinned white Grapes require a strong light, such as is produced by bright sunshine, to finish them off properly. Though Vine borders that are raised above the natural level, and are otherwise well drained, will not become sodden or waterlogged from even the exceptional rainfall of the present season, yet I am afraid, where the drainage is imperfect, and the composition of the border has become close and pasty in consequence, that mildew and shanking will be prevalent. But where this is so, there is an undoubted advantage in being able to trace the effect to the right cause. And we may feel assured, if the composition and drainage of the border are all right, the rainfall, large though it is, will not affect it injuriously. Wherever the damp season has brought into prominence the defects of the border, their remedy is mainly a question of labour and a supply of the requisite materials. No doubt some seasons of the year are more suitable than others for lifting and replanting Vines; and with houses where the fruit is cut or is ripe enough to cut, the sooner the work is done now the better.

Grapes that are ripe may be cut, with a portion of wood attached, principally below the bunches, and the end inserted into a bottle of water in which a little animal charcoal has been placed; they will thus keep as long, if hung up in a dry room—sufficiently but not over ventilated—as if left on the Vines. And if the roots of the Vines can be lifted, and be placed quickly in a healthy medium, a season will be gained, as they will take hold of the new soil and get established this autumn. The work must be carefully done, the materials for making the new border being chopped up,

mixed, and prepared before the old border is interfered with; the same also as regards concrete or rubble, or whatever is used in the foundation. In the case of concrete the materials could be ready for mixing, so as to get the foundation in as soon as possible; indeed, where the labour power is ample, after a portion of the border has been cleared, all the roots carefully packed in damp litter, and covered up with mats, another party may commence the laying of the foundation; and when sufficiently set or consolidated, the new border may be made tolerably firm, and the roots laid carefully in the new soil at once. Unless the work can be done before the leaves fall, it will be better to delay it till March or April; and this perhaps will be the best time to renovate or renew the borders of all late houses. Where the border is partly inside and partly outside the house—which I think is the best arrangement—either portion may be renewed without giving much check to the Vines if done at a favourable opportunity, and if the work is carefully and quickly carried out. But in all such work promptitude has a great value.

In all cases where the subsoil is bad, some efficient means should be adopted to keep the roots from entering it, and from four to six inches of good rubble and lime concrete is the best. The bed of concrete should have sufficient fall from back to front to cause all water that soaks through the border to pass quickly off to the drains in front. Borders of greater width than 10 ft. should be intersected with cross drains, laid on the face of the concrete 6 ft. apart, to empty into the drain in front. From 9 in. to 12 in. of stones or brickbats should be laid on the bed of concrete to drain the border, the largest stones being laid in the bottom, and a layer of small stones or broken bricks on the top, so as to ensure the whole being kept clean and free from soil; and to still further ensure this, a layer of sods should be placed, grass side downwards, on the stones before the border is made. A border so constructed will last many years, with occasional renewals of the surface and round the front and ends. There are some soils that are so well drained naturally, from the subsoil being of a porous nature, that generally, so far as ordinary cultural operations extend, they require no artificial drainage. But Vine borders, where superior results are sought, will have something better than ordinary cultivation. The annual top dressings, and the richer character of the soil generally, from frequent manurings, will gradually make the border more retentive—so much so, as in wet times to prove a bar to the speedy evacuation of surplus water, and the roots may receive a sudden check from the lowering of the temperature by the greater accumulation of water. It is at such times that drains prove valuable in soils that are naturally dry; and the removal of stagnancy only once will pay for the labour and expense of drainage.

There are some neighbourhoods where the soil is naturally suitable for Vine culture, and to which beyond trenching and adding bones or other manure little need be done. I know more than one place where large Graperies are established upon sites so suitable as to require no addition beyond manure. But these are exceptional cases, and, speaking generally, it does pay in the majority of situations to take extra pains in the preparation of the border, as it will often make the whole difference between good and bad fruit. This being so, the present season seems peculiarly fitted for taking stock of the Vine borders generally, with a view to remedy any defects of construction or composition.

Wherever Vines are lifted before the leaves fall, the house must be shady in bright weather, and a damp atmosphere maintained inside in order to keep the leaves up, as it is only by their action and influence that root action can be set up.—E. HOBDAY.

IRRIGATING STRAWBERRIES.

FIVE of us went the other day to inspect a system of irrigation. The place is a mile from the centre of the neighbouring village, and we found a force of several hands picking Strawberries from rows of very vigorous plants, the result of a system of irrigation. They were just prime for market after all other berries from the vicinity had ripened and were gone, save a few insignificant boxes that could in no way affect the market. It took us a very short time to learn the following facts:—

1st. Under the system practised the berries were two weeks later than the general crop of the vicinity, and they were sent into the market when the prices were remunerative.

2nd. The plants were vigorous and independent of rains, so that every berry that set could reach perfection in size and flavour.

3rd. The necessity of picking every day or every other day for the sake of saving a few berries that would otherwise become over-ripe, was entirely obviated, and a picking once in four or five days would be very large and a rapid gathering at the least possible outlay, was accomplished.

4th. The fruit, becoming more mature without losing its firmness, was more luscious, and yet scarcely anything was lost in the charac-

ter which every berry picked for market must have to hold its shape until sold.

5th. The vigorous condition of the plants gave protection to the berries from the direct rays of the hot meridian sun, which preserved even those which were over-ripe from so soon losing flavour.

We then inspected the method of irrigation, and while walking to the fountain-head we had ample opportunity to view the vegetable garden, which we found in a most flourishing condition. The Cabbages and Tomatoes particularly attracted our attention, because of their forwardness.

"How's this?" we enquired of the owner; "your method of irrigation puts back your Strawberries but puts ahead your vegetables."

"Cabbages," he replied, "are advanced, to be sure, because it is leaves we are after, and our method tends to a very rapid growth of foliage. But with Tomatoes I need to make this further explanation: the fruit develops in size very rapidly, but should we continue to regularly apply our water, the ripening process would be retarded the same as with Strawberries; but as soon as the fruit is of fair size, we withhold the water, and they ripen rapidly. We have found that there is a good deal of study connected with properly and economically employing irrigation in the garden." So we thought, after witnessing this anomalous state of things.

"We water," said he, "only to supplement the rain. If the season is a wet one, we employ our artificial system little or not at all, and in such seasons get no profit from our investments; but generally some time during the season we get a drought that shortens some crop, then we irrigate that crop, and have the advantage of our neighbours."

The fountain of supply from which the water was taken, we found to be a spring, dammed up at a point which was a little higher than most of the garden. The water was conveyed in a wooden conduit made of 2 in. plank, rendered water-tight by the use of coal-tar. It was, perhaps, 8 in. wide and 1 ft. deep. At intervals of about 8 ft. auger holes were bored near the top of the conductor. The rows of vegetables and Strawberries run at right angles to the line of the conduit, and are so arranged that each alternate space between the rows comes opposite a hole in the conductor. When the water is wanted in any particular locality, a cut-off is made just beyond the opening at this point, and the water being let on at the fountain-head pours out a nice stream and follows down the row. The surface of the ground has been carefully graded, so that the progress of a stream of water let on is very slow, giving plenty of chance for the water to settle about the roots of the plants. Having once secured a place with the natural arrangement of a spring at some point higher than the general surface, this process of irrigation is an inexpensive one.

A word regarding the management of the Strawberry fields at this place. After the berries are removed, the ground between the rows is thoroughly cultivated through the remainder of the season; the plants run together in matted rows, and in this condition are wintered. Early in spring a good coating of long stable manure is given. That which has begun to decompose a little, or that in the making of which short wheat straw has been used, is preferred. This manure is spread evenly over the surface and the plants make their way through it easily. By the time the berries are ready to be picked it is all down close to the ground between the rows. The covering is placed on in the spring to retard the blossoming as well as to preserve from evaporation the water that is employed in irrigating the rows.—*Rural New Yorker*.

Late Grapes.—The dark sunless season which we have experienced has had a good effect in keeping down insects on Vines. I have not seen any symptoms of red spider this year on either early or late Vines; this, no doubt, is the reason why Grapes, as a rule, have coloured so well, and beginners in Grape growing will do well to observe how essential it is to keep the foliage clean and free from insects if well-coloured Grapes be desired. Late Grapes are very much behind their usual time in changing colour, and the same remark applies to the wood; fire-heat must, therefore, be given at once freely and early in the afternoon, to assist the sun-heat, which is now on the wane; otherwise, the result will be immature fruit and wood, which produces bad-keeping Grapes and disappointment as regards the future crop.—JAMES SMITH, *Waterdale*.

Premature Ripening of Pears.—Although Pears, in common with other fruits, are extremely small and backward this season, many of the ordinary early ones are already dropping from the trees, apparently ripe but with very little taste in them. In addition to the extraordinary rainfall and low temperature, there appears something ungenial in the atmosphere, as, now the long expected warmth has arrived, crops do not seem to thrive as they do in ordinary seasons.—J.

GREEN CHISEL AND OTHER PEARS.

ALTHOUGH lacking the fresh and abundant flesh of the Jargonelle, and the, to some, agreeable if full musky aroma of Williams's Bon Chrétien, there is, nevertheless, much to appreciate in this little old-fashioned Pear. As gathered from the tree its plump little fruits are fresh, crisp, and juicy, far more refreshing to my mind than the Williams's, now so abundant; indeed, it is only excelled in cool juiciness by that distinct and beautiful Pear Louise Bonne de Jersey, the taste of which, like that of the Jargonelle, one could recognise, even were a fruit handed to one in the dark. I have not Hoggs's "Fruit Manual" by me, but here is Scott's description of the Green Chisel, and a good and short account it is: "3 size, 2 qual., August. Roundish turbinate; skin green, with a slight brownish tinge next the sun; stalk long and straight, and inserted without depression; eye large and open, with a few protuberances around it; flesh white, juicy, and sugary. An old sort, cultivated since the year 1650. It is sold in the Paris Markets in large quantities under various names." The Trout or Forelle Pear of the French is a most beautiful fruit; indeed, this and Benrre d'Amanlis Panache are the most handsome perhaps of all Pears. They are not either the best or most useful—not to be mentioned in that way "in the same breath" as, say a creamy-yellow Marie Louise from a sunny wall. I have in my eye another handsome fruit, the true Louise Bonne, which I well remember to have seen at Chiswick in the old days—a medium-sized fruit of a peculiar shade of soft, wax-like creamy-yellow; indeed it was difficult to imagine it a real fruit, so perfectly concolorous and delicate is its skin on some soils. Scott's description under this name must be of some other fruit, or his specimens may perchance

Section of Green Chisel Pear.

have been from an unfavourable locality, for of all fruits the Pear is perhaps the most affected by change of soil; what is first-class in one place and a great "cropper" may only be fit for pig feeding or a non-bearer in another garden. I am extremely fond of the delicious little bronzy-red Seckel, which at its best is a delicious *bonne bouche* to any lover of good fruit. The secret of Pear culture may be best taught to oneself by visiting neighbouring gardens to note the kinds that succeed, and the stocks on which they are grafted; then go home and plant young bush trees. Plant them well in good fresh soil—turfy loam—a cartload at least to each tree. Mulch with stable manure the next summer. If the Quince stock suits the locality and the varieties worked on it, then plant the Quince for early fruit. B.

HEALTHY APPLE TREES IN COLD CLIMATES.

PROF. W. J. BEAL writing in the *Farmers' Review* says: We know there is much difference in the capacity of varieties of Apple trees to endure severe weather. In one case with which I am acquainted trees of the Baldwin in an orchard were nearly all killed, while in another orchard less than half a mile away with nearly the same elevation, the Baldwin trees were uninjured. The soil of the first was black loam, and relatively low and flat; that of the other gravel and relatively a little elevated. To prepare trees to endure severe weather, I would prefer to set with pains, in well-prepared soil, trees one or two years old of some variety known to be quite hardy, then insert several buds or grafts of such varieties as are desired in the tops of the young trees. Set the trees leaning against the prevailing wind; start the tops very low near the ground; encourage a leader in the centre of the tree. Thin the top moderately all around

the outside, no more in the centre than on the sides. Never cut off a limb much if any over 1 in. in diameter, and avoid cutting any limbs from a large limb. Rub off the young shoots if they are not desired. Each tree should have plenty of room; in large varieties when twenty years old or more 40 ft. each way will not be too much. The rough bark should not be scraped from the trunk or large limbs, as it affords some protection, but insects should, of course, be diligently kept off. The cultivation should be varied according to the nature of the soil and climate, so that the trees shall start off well in the spring, and stop growing early enough to mature the young wood and buds. This growth can be controlled, in most cases, by tilling the soil more or less, by using or withholding fertilisers. The growth should be moderate, not rank nor stunted.

While the trees are young, the surface of the ground should be heavily mulched for 4 ft. each way from the tree. In no case must a tree be allowed to over bear, especially when young. Most clay loams—good strong wheat lands—are excellent for Apples, provided they are always artificially drained. The importance of thorough drainage for healthy trees in a cold climate needs to be emphasised. It is often the key-note to success, and the one often neglected. Another point of scarcely less importance is elevation; the land should be relatively high compared with other land in the neighbourhood. A difference of 150 ft. in elevation has been known to show within one mile, in a still, cold night, a difference of 17°. From this elevation the cold air rolls off like water down a slope. If a person is obliged to plant Apple trees on ground which is nearly flat, it should be first ploughed into high ridges, the higher the better. Plant the trees on the ridges after they are made, and not make the ridges after setting the trees. The time has come when more attention must be given to a proper selection of site, soil, and drainage, if the owner expects good returns for his labour in planting and caring for an Apple orchard.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Remedy for Mildew.—At a recent meeting of the Academy of Sciences in San Francisco, Dr. Arthur W. Saxe, of Santa Clara, made, according to the *Prairie Farmer*, a statement of a series of experiments made by himself during the past few years, to the effect that a solution of copper, sprinkled over Grape Vines just before the starting of the buds, is far better than sulphur to prevent mildew, being cheaper and more easily applied. He stated that during no season had he seen any sign of mildew when he used this solution, but that one year he neglected to apply it, and the result was that the Vines were badly affected.

Denyer's Victoria Plum.—Amongst the few outdoor fruits that are doing well this year may be reckoned this well-known Plum, a variety that has received more commendation than any other kind this year. It succeeds well as a pyramid or bush tree, but it well deserves a wall, as in seasons like the present a well-ripened dish of Plums is certainly preferable to a meagre crop of Peaches, that, except in the case of early sorts in favoured localities, do not look like ripening at all. The Victoria is a sort moderately strong in growth, and, when well ripened, in addition to being a good dessert Plum, it is extremely useful for culinary purposes, either ripe or green, as from its free-bearing properties in most years it requires severe thinning to allow the remaining fruits to come to perfection. The latter make excellent tarts in a green or immature state, and when ripe they make an excellent preserve, as, for the size of the fruit, the stone is very small.—J. G., *Linton*.

Black Currants.—Amongst fruit crops that have been profitable this year must be named Black Currants; for not only have they yielded generally fair crops, but their price has kept up well, the bulk of the crop selling at from 10s. to 11s. per sieve, which is greatly in advance of Red or White Currants. The cultivation adopted here in Kent that produces good results is extremely simple, a great many being grown in orchards between other kinds of fruit trees, such as Apples and Plums, which being planted in rows 18 ft. apart, allow space for two rows of Black Currants, or other bush fruits between them. They are well thinned out at the winter pruning, and manure is dug in between the rows, as they are gross feeders, and delight in a rich, moist soil. They are greatly benefited by a mulching of manure over the surface to prevent evaporation, and keep the stiff land in this locality from cracking, thereby admitting the drought. When grown in open quarters, 6 ft. is the regular distance at which they stand apart each way; and in good rich soil they soon occupy all that space. The favourite sorts here are the Black Naples, a very robust, sturdy grower, a good cropper, and rather late; Baldwin, a large berried variety; the Grape or Dutch Black, an old, well-known kind; and Lee's Prolific, one of the best new sorts, highly spoken of for market purposes. Black Currants

are not so liable to the attacks of birds or insect pests as other bush fruits, and are generally a reliable crop; so that any one having rich, moist land will find them to yield as good returns as anything in which he can invest.—J. G.

TREES, SHRUBS, AND WOODLANDS.

MAGNOLIA GRANDIFLORA.

Mr. Groom (p. 122) has not said too much in favour of this plant. Its claims can indeed scarcely be overrated for the purpose he mentions. The broad, handsome, glossy leaves and massive growth render it one of the most distinct evergreens that we possess, and a bush or two of it in the pleasure grounds impart quite new features thereto. I have often remarked that this shrub harmonises in a peculiarly pleasing manner with most forms of architecture, and that when employed either in the way of drapery or as growing in its own free natural way, it imparts an air of richness and even grandeur to the surroundings. Single isolated specimens upon the Grass have a fine appearance, but a well-developed group is truly grand. When in Normandy I had a mass of some fifty trees planted upon a raised bed. They grew with great luxuriance and flowered with the utmost freedom; as thus seen no flowering shrub could equal it. When one takes into consideration the remarkable hardness of this shrub—I say remarkable, for it passes unscathed through winters which sweep off wholesale many of our commonly considered hardy shrubs—the beauty of the foliage, and the agreeable fragrance of the lively pure white flowers, one may reasonably be permitted to express surprise that it is not more commonly grown. I was recently passing through some of the most populous districts of Surrey and Middlesex, and the Magnolias there seen in the villa gardens might be counted on the fingers of one hand. In one garden I remarked a pair of handsome bushes flanking the entrance to the dwelling, the effect of which was of the best description. There is probably more than one cause why the Magnolia is not more extensively planted. In the first place many do not know that there are two distinct varieties, one of which but seldom flowers—and then often but sparingly—until old; whereas that which is known by the name of the Exmouth variety commences to throw up good blooms at an early period of its growth. It is this latter kind which should be sought for; but it unfortunately happens that many nurseries hold a stock of the older kind, and purchasers, not being aware that this difference exists, do not make proper enquiries upon the subject, but plant in good faith that which is supplied to them, and, finding but little reward in the shape of bloom, naturally conclude that our climate is not favourable to its development. I have recently seen a plant of the true Exmouth variety, quite a small bush, but which is already commencing to throw up bloom. I may mention that it came from Messrs. Pince & Co., of Exeter, where it may readily be obtained true to name. This free-flowering kind is, I believe, considerably dearer than the older variety, but a little expense in purchasing should not be grudged if it will secure an early and plentiful yield of fragrant flowers. I am also inclined to believe that this Magnolia is often transplanted at the wrong time of year. I believe that at M. André Leroy's nursery, at Angers, no trees are warranted to succeed unless transplanted in August, and I well remember that at the Paris Exhibition of 1867 some large pyramids which were moved in March dropped a considerable portion of their foliage, whilst those transplanted later on, and which were planted in a hot time, received no check. The plants should be moved at a time when the earth is warm, so that the roots immediately grasp the new soil, in which case there is but little danger of the leaves falling. In the case of the Magnolia if once the foliage drops there is but slight chance of renovating the plants; when once the lower leaves are gone the beauty of the specimen is marred, never again to be restored.

J. C. B.

HORIZONTAL EXTENSION OF TREE ROOTS.

This is a subject not always sufficiently taken into account in planting trees in particular situations, as, for instance, near fruit tree borders, in which their presence, if in any considerable quantities, is fraught with the worst consequences, especially if from time to time they cannot be cut back. So far as my own observation has gone I have found that although some trees extend their roots naturally much further than others, nevertheless the nature of the soil has a good deal to do with their rambling far or keeping comparatively near home. Where there happens to be a deep rich loamy soil, neither too wet nor too dry—such, for instance, as the alluvial deposits in the immediate neighbourhood of a river or stream of some extent—the roots of such trees as Oak, Elm, Plane, Horse Chestnut, Spanish Chestnut, Lime, Hornbeam, Ash, and Beech do not, as

might be supposed, run so far as in poorer, shallower soils, more especially if there should be a "pan" or water-holding under-stratum nearer the surface than the depth to which the roots would otherwise naturally descend. When they happen to occupy a medium that affords all the food they require within a moderate distance, as might be expected, they adapt themselves to the circumstances under which they are placed, and do not extend far abroad, this being to a considerable extent governed by the strength and size of the individual examples of trees according to their kinds, for the underground portion—viz., the roots—of any tree, as a rule, will be found to proportionately correspond in bulk with the above-ground part—the trunk and branches. It is scarcely necessary here to point to the fact that Nature in this, as in other works, directs the roots in a way that enables them to perform the double duty of extracting from the earth the food needed for the sustenance of the above-ground portions, and also in holding and preserving the tree in its proper position. Evidently, in order to fulfil this latter purpose, the evergreen kinds, retaining, as they do, their leaves all the year round, thus offering correspondingly more resistance to the winter gales, have the bulk of their roots lying horizontally near the surface, where they are in the best position to resist the greater strain made upon them than is brought to bear on those of the at-this-season deciduous kinds; yet none of these that I have ever had an opportunity of tracing extend so far as some of the deciduous species. Amongst evergreens the roots of the Scotch Fir have travelled the furthest of any I have met with—47 yards from the trunk—but it was a large example with a big bare stem, so far as I was able to make out, some 240 years planted. The roots of several Silver Firs extended 45 yards away from the bole in considerable quantities as thick as one's finger, and had their small fibres been followed to their extreme ends they would have reached a few yards further. Cedar of Lebanon I have seen with its roots 45 yards away, but this was the extreme length. Amongst all other trees, deciduous or evergreen, English Elm has come under my notice with the longest roots. A number of years since when we were digging gravel, I came upon roots of this tree 54 yards in length, 1 in. in diameter, and doubtless they went several yards beyond this, but we could not follow them to the end. There was no mistaking the distance they had come, for the nearest and only tree for a considerable distance was an Elm, an old big example, from its appearance, I have no doubt, above 200 years old. Beech I have found over 45 yards from the tree; Oak and Plane had reached about the same length; Ash, wherever I have had an opportunity of tracing them, have not extended so far, being more inclined to fill the ground near home. The above are the greatest extensions of roots that have come within my observation. Often in open drains or other excavations in the neighbourhood of these kinds of trees, I have found that the roots did not reach nearly so far, being, I have no doubt, influenced by the nature of the soil or other local circumstances. A knowledge of the subject has, I admit, more of interest than real utility attached to it, nevertheless, for the reasons I have stated, in exceptional situations it is well to be able to form an estimation of the length the roots of trees will attain. I feel a little anxious to know if the roots of Elm have been found further extended than those in the case I have instanced. That they are most hungry food hunters I have often had evidence, I recollect once having some Vines under my charge, the border of which was some 30 yards from a good-sized Elm; to prevent the roots of the Elm entering it, a 9-in. brick wall set in cement, and 4 ft. deep, had been built round the outside, coming up to within 4 in. of the surface, over which was a grass verge, and beyond this a broad deeply gravelled walk. The Vines showed signs of weakness, and on examining the border, I found many more Elm roots than Vine roots. When we came to remove the old border completely, with a view to making a new one, and planting fresh Vines, I discovered that none of the Elm roots had got through or under the brickwork, but, in the few inches of soil above its top, they had got over in quantity, several being as thick as a man's wrist.

T. BAINES.

Scarcity of the Hemlock Spruce.—Official returns show that in New Brunswick the Hemlock Spruce (*Abies canadensis*) is becoming as scarce as in adjacent parts of the United States. "It is found only in certain parts of the island, and is rapidly diminishing, owing mainly to the ravages of fire, to which it is peculiarly subject, and to the fact that a large number of trees are cut down for the sale of the bark only, the timber being left to rot in the ground." The reports from the other parts of the Dominion bespeak the same reckless waste of all kinds of timber. In British Columbia, which has an area about twice that of the United Kingdom, two-thirds, or in round numbers 110,000,000 English acres, are still covered with timber. A variety of the Hemlock Spruce is one of the commonest trees there.—"Timber Trades' Journal."

VARIEGATED TREES AND SHRUBS.

THERE is nothing which adds to the beauty of garden scenery so much as judiciously arranged groups of ornamental shrubs and trees; but how often do we meet with shrubberies which present a dull, monotonous effect simply because there is a lack of variety in the forms and tints of the subjects employed. During the spring and early summer months a few of the finest flowering shrubs intermixed with evergreen kinds give to ordinary shrubberies a picturesque appearance; but, after these are past, the sombre tints of green leaved trees and shrubs, unrelieved by variegation, is prominently conspicuous; but where variegated-leaved plants, mixed with those of golden hue, are planted, an ornamental appearance is ensured for the greater part of the year. The taste for variegated-leaved plants is becoming more general than formerly, and each season has brought with it a host of new forms of silver and golden leaved plants, till now there is scarcely a hardy tree or shrub the leaves of which do not present some form of variegation, as a recent walk through Messrs. Lee & Son's Arboretum at Isleworth, where there is a rich collection of such plants, amply confirms. Here one may meet with almost every kind of variegated tree or shrub at present known, and these, combined with others of all descriptions, produce a highly picturesque effect, especially at this particular season, when the majority of the plants are assuming their brightest hues. Amongst the most conspicuous of these we noted the beautiful tri-coloured Dogwood (*Cornus elegantissima*), alluded to last week. The form with the variegation without the suffusion of pink is also a desirable shrub, as the white margins of the leaves are so well defined; it is called *C. Mas argentea variegata*. The variegated cut-leaved Elder is a very handsome shrub, and one which should be seen in every shrubbery. Its defect, however, is that oftentimes the variegation is confined to a branch or two only, the leaves of which become creamy-white, and the rest of the plant quite green, though in this state it is effective. In this nursery the variegation is developed much better than we have hitherto observed, a circumstance probably owing to the exposed position of the plants. The Judas Tree (*Cercis Siliquastrum*) has a pretty marbled variegation, though not very effective. The variegated forms of the common Sweet Chestnut (*Castanea vesca*), the Horse Chestnut (*Esculus Hippocastanum*), and Ash (*Fraxinus excelsior*) are very ornamental, the former having the varieties marked both with white (*alba marginata*) and gold (*aurea marginata*). The variegated Maples are numerous, but none are so effective as the well-known *Acer Negundo variegata*. Of Oaks there are also a goodly number with variegated foliage, one of the prettiest being the Turkey Oak (*Quercus Cerris*). The Tulip Tree (*Liriodendron Tulipifera*), the Lime (*Tilia alba*), the False-Acacia (*R. Pseudacacia*), the Western Plane (*Platanus occidentalis*), the Japanese Sophora (*S. japonica*) the Bird Cherry (*Cerasus Padus*), and a host of other familiar trees are all represented by variegated forms, which are more or less beautiful. The variegated-leaved Privets are especially noteworthy, as they form such effective subjects in combination with the green-leaved kinds. *Ligustrum japonicum*, *lucidum*, and *ovatifolium* are those which possess the variegation.

Though the present season has been adverse to the full development of the variegated plants, it has not materially affected those with golden tints—indeed, the rich hues of some kinds are as fine as we have ever seen them. No better golden-leaved plant is to be met with than the *Catalpa syriaca*, and it should be more extensively planted than it is. Next to this is the Golden Elder, which this season has been highly effective in the parks, &c. A golden form of the common Elm named *Ulmus campestris aurea Rosseelsi* is a striking tree of a somewhat drooping habit and forms a mass of rich yellow foliage. *Alnus glutinosa aurea* is another valuable addition and forms a fine contrast with the green foliage of others. Of other kinds with similar tinted foliage there is a long list to be found in this collection.

Conifers are numerous represented by golden and variegated varieties, the most conspicuous of which are *Cupressus Lawsoniana alba spica*, the variegated Deodar, *Thuja Lobbi aurea variegata*, Golden Chinese Juniper, and the Virginian Red Cedar. The silver-leaved evergreen *Sequoia, S. sempervirens*, is another valuable form as it makes a striking contrast to the deep green tint of the original. The same may be said of the silvery-leaved variety of the erect growing *Cupressus Lawsoniana*, which will be more apparent when it is seen in a larger size. Of golden forms there are a good many, and all very desirable for associating with those with green foliage.

Diversity in habit of growth is another important point to be considered in selecting subjects for effective grouping. Of pendulous growing trees and shrubs there is a great variety in this nursery, and equally numerous are those of stiff erect growth and every intermediate style of habit between these extremes. The varieties with cut foliage afford another interesting feature, some of which

have an extremely graceful aspect, whilst to others it gives the appearance of being in a depauperated condition. W. G.

TWO CALIFORNIAN SHRUBS.

THERE are probably none of our native shrubs more worthy of cultivation than *Rhododendron occidentalis* and *Pickeringia montana*. Both have such a wide range of habitude and altitude that with a little care in the selection of well-drained soils they would probably do well under any ordinary circumstances.

According to our "Geological Survey," the former is found by streams throughout the State, but I have never found it except on the tops of ridges, generally in company with the *Pickeringia*; the latter, however, seeming to have a much greater range, extending to the low ridges bordering the valleys. The *Rhododendron*, or as it may be more properly called, *Azalea*, presents a magnificent sight when in bloom, each stem appearing an immense wand of dazzling white, thrown into beautiful relief by the dark green of the plant's leaves. On a near inspection many of the blossoms show a fine dash of yellow, and I am inclined to think age gives to many of the blossoms a bright rosy tinge. The flowers are of much firmer texture than our greenhouse *Azaleas*, and a sweet odour is not the least of their attractions; the plant is deciduous.

In my several attempts to transplant it to my garden I have been unable to give the plant what I consider a fair trial; several grew nicely in boxes, and formed an abundance of fine roots, which were unfortunately drowned by over watering; a few bloomed in my garden, but they fell victims to the disturbing influence of the gopher. Any piece of its knotty crown will send up new sprouts, so the plant can be had in any shape.

Pickeringia montana seems to be partial to foggy situations, for in such it produces leaves enough to hide its nakedness, as well as a brilliant show of its spikes of crimson bloom and a few seeds, while on fogless ridges it bears but few leaves and blossoms, forms no seeds, but its grey, thorny branches present an almost impenetrable barrier to all but the smallest animals. This property would suggest its use as a hedge plant, as it would grow in the driest places, and where there was moisture enough it would present a magnificent spectacle. It is an evergreen, and I believe will propagate readily from its underground stem or root.—J. B. HICKMAN, in "California Horticulturist."

Oreodaphne californica (p. 142).—I fully agree with Miss Hope in her estimate of the beauty of this shrub, but not in her advice to use it for its scent in nosegays for hospitals. The scent is very pungent, and though pleasant at first very soon becomes unpleasant and even offensive; and it is apt to cling a long time to the hand that touches it. I have a larger specimen than either of those mentioned by Miss Hope, so I speak from experience.—HENRY N. ELLACOMBE, *Bitton*.

Pruning Laurels.—Evergreen trees and shrubs of all kinds have made an exceptionally vigorous growth this year owing to the dripping, sunless weather; and hedges and banks of Laurels, Privet, Yew, &c., will require more than ordinary attention as regards pruning. If left too long they look bare when cut, and the only way to have dense hedges always full of evergreen leaves is to clip or cut two or three times during the growing season. I am no great advocate for the shears, but in some cases we cannot dispense with their use, and the only way in which we can get over the difficulty is to use them often when the growth becomes so dense and compact that one can scarcely detect how the Laurels or other hedges have been pruned, for, if done by skilful workmen and good tools, an even, unbroken surface of the freshest green is the result. If all clipping is completed at once, the growth made during the rest of the season will be enough to clothe the surfaces with a dwarf spray, just sufficient to take off the straight-faced aspect of ordinary hedges. It is a mistake to let hedges get into a neglected state, as it not only takes more time to rectify them, but they look unsightly for years afterwards.—J. G.

Effective Planting.—Variety in landscape scenery is pleasing, especially when viewed from the windows of a mansion or from terraces or other elevated parts of the garden. A clump of Golden Elders, for instance, planted on a hillside in proximity to a belt or plantation of sombre Pines could not fail to produce a striking effect even a long distance off. Ordinary shrubberies and plantations might be made much more cheerful looking than they are by the introduction of gold and silver and other forms of trees and shrubs, such as the following, viz., Golden Catalpa, silver Acer, purple Acers or Maples, purple Filbert, the various golden and silver Elms, purple Beech, silver Limes, golden and silver Poplars, the graceful

silver Birch, the new weeping purple Birch, golden Acacias, silver and golden Cornus (various), green Acacias, Liquidamber, the Paulownia imperialis (with its fine foliage), golden Laburnum, and golden-scarlet Oaks. Of the last there are many beautiful shades and tints, and the leafage of some of them is of very large size; the scarlet and bronzy hues producing grand effects, especially towards the end of the season. Very many others might be named which, when associated with flowering shrubs and trees, would look well in any landscape. A few weeping trees, and also variegated Hollies, golden Yews, golden Retinosporas, golden Thujas, and many others of recent introduction too numerous to name, would all form materials which in the hands of skilful planters could not fail to produce charming results.—GEO. CANNON, *Ealing*.

ONE YEAR'S SEED SEVEN YEARS' WEED.

THOSE among us whose views are far removed from Mr. Gladstone's, and who by no means look with favour on parts of his political career, must nevertheless admire the versatility of his genius and the delightful way in which he imparts the knowledge he has acquired during the course of a somewhat extended life. He allows others to reap with him the golden harvests of his toil. Our Cincinnati, no longer at the head of the nation's affairs, is fain to content himself with rural pleasures. He has evidently given much time and patient consideration to the subject of gardening, and he communicates his knowledge in a very agreeable and practical manner. Most of us have read with pleasure the account of an address delivered in the Park at Hewarden, at the horticultural show held there, when Mrs. Gladstone presented the prizes. I will merely draw the attention of the readers of THE GARDEN to what was said about weeds.

Mr. Gladstone, after urging the necessity of more spade husbandry, quotes from a book on "Cottage Gardening," by Mr. Badger, who describes a weed as "a thief and a robber." He goes on to say, "A weed is a destructive noxious thing; it occupies the room of something which is useful, and draws nourishment from the ground, which ought to be applied to a different purpose. As to robbers of the human kind, they are immediately turned over to the police, but weeds are not less truly thieves on a larger scale. The probability is that weeds in this country rob farmers and cottagers of a great deal more than all other depredaters put together. Weeds should never be allowed to seed, for 'one year's seed seven years' weed.'" This morning, which was warm and sunny, with a fresh westerly breeze, whilst taking my usual country walk I found my coat covered with a quantity of Thistle-down; the air seemed full of this. Mr. Gladstone's words recurred to my mind, and I endorsed all he said on the importance of clearing the ground at this season, of weeds to prevent their seeding. The neglect of this needful precaution is not only ruinous to the fields and gardens of the careless cultivator, but it entails great trouble on others of less slovenly habits. It is difficult to calculate how much time is thus wasted, and it is sad and disheartening indeed for the unfortunate farmer whose land adjoins that of the man who is ably described by an ancient writer in these words: "I went by the field of the slothful, and by the Vineyard of the man void of understanding: and, lo, it was all grown over with Thorns, and Nettles had covered the face thereof, and the stone wall thereof was broken down." Without entering into the question as to whether the large amount of ground occupied by hedges and ditches in this country may be put down as unprofitable and waste land, it cannot have escaped the notice of the most casual observer that the neglect of clearing these of weeds before the seed time arrives causes them to become fruitful nurseries of these useless plants. There cannot be found more troublesome and expensive weeds to eradicate than Couch Grass or Quitch, Thistles, Dandelions, and Dock. The former, when infesting light land, has sometimes to be removed by cartloads. Now much of this harvest of pests to the farmer and gardener has been produced by self-sowing from plants growing in ditches and hedges. The seeds are small and easily carried away by high winds.

Our officers of health spend a great deal of time and the rate-payers contribute large sums of money to compel men to dispose of the house refuse and sewage, which if allowed to remain in their midst would produce a vast amount of disease; but this compulsory power and supervision is altogether wanting in the case of the slovenly cultivator of the soil. Let us hope in our advanced age that the appointment of a Minister of Agriculture and Horticulture is not far distant, and that probably when our eloquent lecturer is summoned from his retirement to take his place in the councils of his country, he will arm that Minister with plenary power and authority to compel the destruction of useless and noxious plants. Every acre of English ground brought into cultivation is most valuable and ought to be turned to the best account. If kept perfectly clean and

well managed, the produce will be of better quality and more abundant. Thus whilst the supply of food for man and beast is largely increased the money value of the land will be much enhanced.

Hillside, Newark.

W. NEWTON.

PLATE CXCVII.

GROUP OF NEW AZALEAS.

Drawn by CONSTANCE PIERREPONT.

DURING the past twenty years a great improvement has taken place in these fine spring and early summer-flowering plants. The continental raisers especially have produced varieties of large size, with finely formed blossoms, either self-coloured of some distinct shade or handsomely striped and flaked, and all remarkable for abundance of bloom. It is one great distinguishing characteristic of the Indian Azalea that it flowers most profusely, and that year after year, if properly managed. Owing to this and to other qualities of a strikingly useful character, many hundreds of new, and in not a few instances greatly improved varieties have been introduced to cultivation, and many raisers have devoted much time and attention to obtaining new forms by means of careful cross-breeding.

In the accompanying illustration are representations of a few of the newer kinds. Fürstin Bariatinski (No. 1) has large white flowers, flaked—sometimes very broadly—with a pale carmine-red; the blossoms are of fine form, stout, and the trusses of flower bold and imposing in character. It is from the collection of Messrs. W. Paul & Son, the Nurseries, Waltham Cross. Mlle. Léonie Van Houtte (No. 2) is a very fine variety, the large and well-formed white flowers being flaked with rose and dashed or spotted here and there with sulphur-yellow. Souvenir du Comte de Gomer (No. 3) is remarkable for its rich colouring, the flowers being of a vivid crimson-red hue, and very striking in appearance, and also of fine form and substance. Flambeau (No. 4) is of a glowing crimson colour, and is regarded as the deepest coloured Azalea yet raised; it is also singularly bright and effective. The last three are from the collection of Messrs. Veitch & Sons, Royal Exotic Nurseries, King's Road, Chelsea. A few of the newer Azaleas that are most desirable varieties to cultivate will be found to be the following: Bijou de Paris, white striped with rose, extra large; Comtesse de Beaufort, rich rose, with a deep crimson blotch on the upper petals, extra fine; Grand Monarch, deep pink, shaded with warm rose, very large; Jean Vervaene, deep rich salmon, distinctly edged and sometimes striped with white and spotted with dark on the upper petals, extra fine; Madame Ambroise Verschaffelt, violet-rose, shaded with white, the upper petals finely marked, very showy; Madame de Grévé, deep rose, edged with white, striped with salmon, and having dark spots on the upper petals; Marquis de Lorne, orange-red, very free and showy; Mrs. Turner, bright pink, margined with pure white and spotted with crimson, a very beautiful and useful variety; Noble Belgique, white ground, with large deep rosy spots, flowers of large size; and Sigismund Rucker, rosy-pink; netted and edged with white, and with handsome dark blotches, extra fine.

Of late years a double-flowered section has been added to the group of Indian Azaleas. Double-flowered Azaleas are not new, for the old A. Borsig, with its double pure white flowers has been in cultivation for a long time past; but some eight years or so ago a batch of new varieties was sent over from Belgium, and these gained great favour in this country, being so fine and distinct. Some of the best double varieties will be found to be Bernhard Andreas, pure white, and very free; Charles Leirens, dark salmon, with black blotches, very fine and showy; Comtesse Eugène de Kerchove, white, striped with cherry, very fine; François Devos, double red, very showy; Grande Duchesse de Bade, bright orange-scarlet, very double; Imbricata, white, slightly flaked with rose, very double—indeed, the flowers resemble in appearance those of a Balsam; Madame Louise de Kerchove, salmon, edged with white, very fine; Madame Charles Van Eckhoute, pure white, exceedingly large and double, and handsomely fringed; Mlle. Marie Van Houtte, white, flamed with salmon; Souvenir de Madame Rudolph Abel, salmon, edged with white, and spotted with crimson, very fine; and Empereur de Bresil, clear rose, banded with white, and marked on the upper petals with glossy red, extra fine.

Azaleas are much more easily cultivated than many other hard-wooded plants that are grown in pots, and they are not so liable to die off suddenly as is the case with some other things. The Azalea is a plant requiring to be kept in a perfectly healthy condition, and thoroughly clean; when plants are in a sickly condition, it is often the result of allowing them to get over-run with red spider and thrips during the season of their growth. Azaleas are very subject to these pests, and when they infest the plants they are certain to become unhealthy. It is a common fault with amateur

GROUP OF NEW AZALEAS

1. FURSTIN BARIATINSKI. 2. MADEMOISELLE LEONIE. VAN HOUTTE. 3. SOUVENIR DU COMTE DE GOMER. 4. LE FLAMBEAU.

cultivators to keep the soil about the roots too dry, and when the compost about the roots, which become matted together like a ball, gets dry, it is difficult to thoroughly moisten it again with ordinary watering, and the pots should be set in a pail of water till the soil is thoroughly saturated in every part.

One excellent characteristic of the Azalea is that it will stand any amount of cutting from, much more so than most hard-wooded plants. After the bloom is over, the plants need to be placed in a brisk heat and kept well syringed, when they will make a quick growth and become well furnished with buds for another season. After blooming, the plants, except in the case of very large specimens, should be repotted. The large plants will probably not require potting for several years, and must have some weak liquid manure applied to them occasionally. They should be placed in a temperature ranging from 50° to 60°, giving plenty of air when the weather is favourable, and using the syringe freely morning and evening. When the growth is completed, the temperature must be gradually lowered until they can be removed outside to ripen the wood and swell up the flower-buds. In the autumn they must be removed into the greenhouse before frost sets in. The soil best adapted for them is three parts good fibrous peat, one part light loam, one part leaf-mould, and one part sand; and it is very important that the drainage should be maintained in good condition. The foregoing brief cultural remarks, from the pen of an experienced plantsman, may be useful to beginners.

R. D.

GARDENING FOR THE WEEK.

Flower Garden.

Though a great improvement has taken place in the weather, the season is now too far advanced for bedding plants to grow much more, or even to continue as good as they now are, except for a very short period, but by way of giving some little assistance to the prolongation of their beauty, let dead and decaying flowers and foliage be kept pinched off, and the outlines and groundwork of the various designs should be scrupulously preserved by pinching or pegging as may be necessary; all the surroundings, too, such as turf, Box, edgings, paths, walks, &c., should be kept neat and trim. Though the season has been remarkable for high winds, we may soon expect to have more of them, and therefore all tall-growing plants should be securely staked, and climbers tied in. Remove suckers and straggling shoots from Roses, and see that standards are also securely staked. Any recently budded plants should be examined, and those buds that have fairly started into growth may have the ligatures removed. The propagation of the various kinds of soft-wooded and tender bedding plants ought now to be completed, in order that they may have time to get well established in their pots before cold, damp weather sets in. Offsets of many kinds of Succulents can now be had in quantity. All the Sempervivums strike root readily in a cold pit, and in any kind of soil, if not over watered; a good watering when the cuttings are put in is about all that is required till they have rooted. The commoner varieties, such as *S. calcareum* and *S. montanum*, root and winter well on a south border, but till they are rooted and established in the ground they should be netted over, or birds pull them up in their search for insects. The offsets of *Echeverias* should be afforded the protection of glass where practicable; otherwise they winter tolerably well at the foot of a south wall, particularly if planted on an incline to throw off the rain, which is more fatal to them than frost. *Kleinias* and *Pachyphytums* propagate best in spring after the old plants have made new shoots; a temperature that suits *Pelargoniums* does equally well for growing and propagating these. Sedums, Saxifrages, and all other hardy dwarf carpeting plants can be increased to any amount by division, an operation which may be done at any time. These latter are all good plants for winter bedding.—W. W.

Auriculas.—The Rev. F. D. Horner's remark "that Champion (Page) and Freedom (Booth) will be superseded by new sorts before these old favourites can be plentiful" is good news to Auricula growers, and doubtless what Mr. Horner states will be fulfilled. I have been trying to raise a good green edge or two by crossing Apollo (Beeston) with Col. Taylor (Lee) and have a number of seedlings that indicate the cross in the foliage most unmistakably, but what the result may be I am as yet unable to say; of three which have flowered one is a bastard self, the two others are yellow grounds with green edges. Now I do not grow any other yellow ground but the double yellow, and no plant of that was near the seed-producing plants. Whence then comes this curious sport? I can only account for it on the supposition that the Auricula is going back to its normal state, a yellow self. Mr. Horner has obtained the same results at Kirkby Malzeard. It certainly seems a singular phenomenon. Although Col. Taylor is one of the very best green edges, I am informed

by Mr. Simonite, of Sheffield, and other growers that no good seedlings have been raised from it. Our plants are still under a north wall, but all that have produced autumn trusses are being removed and placed in an open situation in order to enable them to form new hearts before the winter.

Carnations and Picotees.—Some 3-in. pots of these, after being layered, were placed in the greenhouse merely to try whether or not the layers would root more quickly, and I am now inclined to think that no advantage is gained by allowing them to remain in the house. Still, I fancy if the plants can be placed under glass for three or four weeks after being layered they are all the better for it, placing the pots again out-of-doors. The young layers make too much growth under glass, and the leaves become infested with green fly. Those who raise seedlings to a large extent will have many good varieties that will flower late. The best plan with these is to lift the plants bodily out of the ground and pot them, layering the growths at once. This will be a very disastrous season for saving seeds of the finer varieties. A dry season with plenty of heat suits the Carnation and Picotee best if the object is to save seeds. As far as blooming is concerned, some of the best growers say they never had a better season.

Dahlias.—Mr. Rawlings, of Romford, once told me that this noble autumn flower can be had at its best about the third week in September, and if the present favourable weather were to last a goodly display could be obtained even this season at that time. It is astonishing to ordinary observers, and most interesting to the lover of flowers and plants, to notice how they seem to recover themselves and, as it were, take advantage of a short period of fine weather. Dahlias are now crowded with flowers and buds, and if the nights are warm there will be a gorgeous display of flowers. Still there are ominous signs that winter will set in early. We read that not far from London the thermometer has already fallen to the freezing point, and at Loxford 34° have been registered, *i.e.*, 2° above the freezing point; as I write, too, the thermometer is falling, and if we have more rain it will be disastrous. The swallows, too, are taking their flight from our shores, another sure sign that cold weather is approaching. There is still plenty of work in disbudding and tying the stems of Dahlias to their supports. If this is not done a gale of wind may make fearful havoc amongst them.

Gladioli.—These ought to be at their best now, but they are not; still, the present favourable weather has wonderfully improved their appearance. Those intending to exhibit spikes of them about the end of this month must now be attentive to tying the stems to sticks as they advance in growth, and it is quite necessary to shade the flowers in some way. If a movable tent can be erected over them, and a light canvas shading be used to screen them from the sun, and also to throw off the rains, it will be a great advantage. Still, this kind of treatment has certain drawbacks, and one is that plants are shaded that ought to be freely exposed, in order that the bulbs may be more perfectly ripened. A very good way to shade is to take from four to five pliable sticks about 7 ft. or 8 ft. in length, and stick them in the ground round the plant to be shaded, then bend them inwards, and tie them at the top over the spike; then place a newspaper over the sticks, and tie it to them at the bottom and top. This arrangement answers better than those who have not seen it tried would be led to expect; the paper will stand sun, wind, and rain, but it will not stand wind and rain combined. Still I have exhibited many hundreds of spikes, all of which were preserved for exhibition in this way.

Phloxes in Pots.—These are still most useful in a decorative point of view for the greenhouse, in which they make quite an interesting display, and when mingled with the glowing tints of zonal *Pelargoniums*, single and double, few arrangements are more beautiful. The Phloxes and *Pelargoniums* can be grown out-of-doors together all through the summer, and may be brought indoors as they come into flower. The Phloxes as they go out of bloom must be cut over, and the young plants should be placed out-of-doors, when they can be watered as they require it; or it saves trouble to plant them out.—J. DOUGLAS.

Conservatory.

For some weeks after this there is generally a greater scarcity of flowering plants for conservatory decoration than at any other season of the year, and the difficulty has been considerably increased in recent years when so many fine and distinct flowering plants have been left unearned for in favour of collections of zonal *Pelargoniums*, and others of like character, which, although well in their way and very useful where the numbers grown are kept within reasonable limits, yet fail to give the satisfaction that more variety is capable of doing; but if the various plants from time to time recommended have been properly prepared, the early autumn scarcity of flowering subjects can be got over with a fair amount of bloom. Where sufficient numbers are grown of the most distinct habited kinds of tuberous Bego-

nias, especially the narrow-petalled drooping sorts generally so much more profuse in flowering than the erect varieties, they will be found very useful. The latest Lilies of the Speciosum section will be also of great service along with Fuchsias treated as recommended earlier in the season, so as to induce them to bloom late.

Lapagerias.—As regards both the red and white kinds of these, although essentially climbing plants and most effective in that way, yet now, when they are becoming more plentiful, there is no way in which they can be made more useful than by growing some in pots so as to admit of their being moved about to conservatories or other places when in flower. Whilst they are of medium size they need not be placed on stiff wire trellises in the way in which large examples are grown in pots, but loosely wound round a few erect green painted sticks inserted just within the rims of the pots. In this way they will have a more pleasing appearance, and when they get so large as to require permanent support there is no necessity for training so close and formally on the trellis as is usually done, for when the flowering shoots are left hanging loosely, they look much better.

Celosias of the pyramidal section, sown at the time recommended and grown on, will be found most serviceable for conservatories, especially where there is a little heat turned on on cold nights and in damp weather; but whilst here, similar to all other plants in a temperature lower than they absolutely like, they must receive no more water at the root than is necessary to keep them from flagging, for although simply annuals, and injury in this way to them not of so much consequence as in the case of plants of a more permanent character, yet if treated so as to preserve their roots as long as possible they will continue longer in a presentable condition than they otherwise would do. The same kind of treatment is also applicable to the old Globe Amaranthus, another subject equally well adapted for conservatory decoration.

Standard Heliotropes and Habrothamnuses managed as recommended through the spring and summer will now take their place in the conservatory, and where a little extra warmth is kept up, later on the Heliotropes will continue to flower almost to the end of the year.

Heaths, the latest autumn flowerers, which are much more backward this year than usual, can likewise be made to do duty in cool conservatories, placing them in the lightest position that can be had, and being careful not to overcrowd them.

Oranges, &c.—Any of these that for a time may have been in Vineries, or similar places, should now be transferred to conservatories. It is in all cases advisable before introducing them to sponge the leaves, and to free them from any insects that may be upon them. Where good gardening is aimed at, this is a matter that at all times requires attention, for one foul specimen taken amongst a clean stock will very soon affect the whole, entailing an unlimited amount of extra labour.

Removal of Stove Plants.—It will be necessary now to remove from this structure any flowering or fine-leaved subjects that have been located here during the summer, as the weather will begin to get too cold for them, and their places may be occupied by such plants as those already referred to. It is scarcely requisite to add that a thoroughly clean condition of the internal portion of a conservatory is an absolute necessity, if anything like satisfactory effects are expected. On such summers as the present the continual use of water overhead, and that which runs from the pots, has a tendency to produce the green, unsightly mould which affects the stone stages and floors, usually more or less present in modern structures of this kind. Water diluted with arsenic, and other destructive agents, is frequently used for cleaning the green substance here spoken of, but there are several objections to this course, and I have found nothing equal to a free use of a good soft scrubbing stone, hot water, and soap. The present is the best season for effecting a thorough cleaning of conservatories previous to winter, including the glass and woodwork being washed, where this is not already done; at the same time all pots should be well washed, so that everything in the arrangement may have a neat, tidy appearance. When such is maintained it does much to compensate for the more limited display of flowers present than earlier in the season.

Greenhouse.

Housing Plants.—In the cooler portions of the kingdom it is not safe to leave hardwooded plants out much longer without there exists some temporary movable protection, such as a canvas covering on rollers, resting on a light wooden framework, than which no more useful appliance exists in a garden, as not only can it be used to keep the plants from drenching rains during the summer, but they will be safe for some weeks yet by running the cover down over them in the evenings when there is an appearance of frost. Where there is not some appliance of this sort they should be got in at once,

previous to which the house, as recently advised, ought to have had a thorough cleaning. Every plant liable to the attacks of mildew should be examined before being taken in, and where any trace of the parasite is found dust freely with sulphur, for not only can the presence of the mould be much easier detected now than when the plants are arranged, but the chances of its affecting others that are free from it are avoided.

Tying Azaleas.—The tying of these plants will, as a matter of course, be regulated by the purpose for which they are required. It is an unfortunate circumstance where plants have to be conveyed in bloom to an exhibition, even for a short distance, that it necessitates their shoots being secured to a much greater extent than for home decoration; for the latter purpose just a single stick to each of the principal branches is all that is needed, so as to keep them reasonably in shape without any formal training. If the tying is done now before the wood gets too hard, the leaves and ends of the shoots will assume a natural position. The whole of the plants ought to be gone over to see that they are free from their worst enemy thrips, as if these are now destroyed along with their eggs no further inconvenience will be experienced from them during the winter, and there is a reasonable chance of the plants remaining free from them when growth again commences. After all the various remedies that have been tried, there is nothing so safe and certain of killing these insects without injuring the foliage as Tobacco water.

Cyclamens.—Plants of these that have been grown on freely under glass near the roof, yet guarded from the sun, will usually be found in a much more satisfactory condition—even in the case of old examples—than when exposed in the open air. The second season after sowing they are generally the most useful; but young stock raised from seed sown about a year ago, where well managed, will by this time have made fine bulbs that will bloom well. They will yet require care to keep them free from aphides and red spider, although the latter pest will not from this time cause so much trouble as earlier in the season. If, however, any happen to be present they will yet injure the leaves to an extent that will much interfere with both the appearance and well-being of the plants, as Cyclamens more than most things suffer from the presence of insects. Plants that have been managed on the exposing-in-the-open-air system after flowering, if not already potted, should be attended to in this respect; but it is much better to defer the operation until they have commenced to push up new leaves freely than to pot whilst they are in a comparatively dormant state, as they rarely take freely to the new soil unless the roots are in an active condition at the time of potting, immediately after which they should be placed in frames or pits where growth can be encouraged. A little warmth will be of very great service, for though they may be grown in a temperature such as that which ordinary greenhouse plants require, still there is no question that treatment slightly warmer is more conducive to their well-being, and in the case of young plants they get up to a useful flowering size in much less time.

Chrysanthemum frutescens.—The partiality which often exists for double flowers has caused many to be prejudiced against these useful decorative subjects, both yellow and white. Their single blooms being so much like those of the common Ox-eyed Daisy has hitherto been in the estimation of many much against them, but their elegant Fern-like foliage, which adapts them equally for cutting as for general decorative purposes in the form of pot specimens, with their easy cultivation and continuous blooming habit, render them amongst the most useful plants that can be cultivated for ordinary greenhouse and conservatory embellishment. Plants that have been grown with a view to their blooming in the winter, which they will do freely if placed in a little warmth, should not be allowed to remain out-of-doors too late. If they have had plenty of room in an open position, and if the leading shoots have been stopped in the early stages of their growth, they will now be strong and sturdy, requiring no support except it may be that of single sticks in the centre of each plant. Cuttings put in now in a little warmth and in other respects treated in the usual way will root quickly. They should be kept in small pots through the winter, and they will make pretty little plants in spring; or they may be grown on to a large size out-of-doors next summer.

Veronicas.—Where these are propagated in winter or spring, and then planted in the open ground with a view to lifting and transferring them to pots for autumn and winter flowering, it is not well to defer the taking them up too long, especially in a season like this when both earth and air are considerably lower in temperature than ordinary. All plants treated in this way should be turned out in soil sufficiently sandy and light to admit of their being taken up with no more mutilation of their roots than may be unavoidable. Although these Veronicas are naturally such free growers that they recover the loss of fibres much quicker than many plants, yet with those that come into flower early in autumn, such as *V. Andersoni*,

injury to their roots more or less interferes with their blooming. They are subjects that require a good deal of water and will bear the soil to be thoroughly moistened as soon as potted in a way that would be fatal to more delicate-rooted plants; they should be set close under a north wall or similar position, so as to be out of reach of the sun for ten days or a fortnight after they are taken up; or if there happens to be room in a house or pit where they can be kept a little close, it will be still better.

Berry-bearing Solanums.—Plants of these also that have been similarly planted out should at once be taken up, using pots no larger than will admit their roots. If the soil is of a free light character, a good portion of it may be shook away and fresh material given them in the pots; these likewise should have the soil thoroughly moistened, or they will flag to an extent that will injure their leaves, a condition that must by all means be avoided, as it is to obtain plenty of healthy green foliage, which contrasts so well with their bright-coloured berries, that the planting-out system is advantageous. If pits or frames are at liberty that can be kept close and also shaded when it is sunny for two or three weeks, it will be the most suitable way of treating them. They may be placed tolerably close for the short time they are kept here, but not so much so as to injure the leaves. These plants, like everything else, are late, and in many places where there is a crop of berries on them grown to their full size, they are yet producing flowers. The points containing these latter will be better pinched off. As soon as they are potted they should have a good washing with the syringe, so as to free them from any dirt that may have got upon them in taking up, and they may be damped overhead once or twice daily in bright weather until the roots have begun to act, after which it is advisable to discontinue anything calculated to promote top growth, as with many the object will be to get the berries of the earliest plants fully coloured with as little delay as possible. I should advise a good stock of cuttings being put in, made from the young, soft, still growing shoots of the earliest plants; they will strike readily treated in the usual way, kept moist in a moderate heat. This I am aware is not the usual season for the propagation of these plants; but cuttings struck now will be much in advance of, and make better plants than, those put in in spring at the ordinary time, or than raised from seeds sown then.

Salvias.—There are many who treat these and other winter-flowering things of a like character on the planting-out system; in all cases they should be at once taken up and potted, treating them very similarly to the Solanums.—T. BAINES.

Hardy Fruit.

Continue to remove, as opportunity offers, the redundant wood from fruit trees generally; most trees are again breaking into renewed growth, the result of the excessive moisture that has so long prevailed, and restriction by pinching must be followed up, both to expose the ripening fruit, and to plump up and ripen the fruit buds for next year. Apricots and Peaches should be kept closely tied, or nailed in, and all sublaterals removed as produced. We gathered Early Louise Peach from the open walls on August 29th, but no other kind has yet any appearance of ripening, and, indeed, the later varieties are still so small that they cannot possibly ripen, and might as well be removed from the trees at once. As showing the lateness of the season we are only now (Sept. 5th) gathering Early Orleans Plums; the later varieties are not near ripe, and the wood is as sappy and green as at midsummer, so that unless we have a most favourable autumn to ripen it there can be no fruit next year; meanwhile, however, and by way of giving some little assistance, keep the growths well stopped, in order that full light and sunshine may act on next year's fruiting shoots. Some few kinds of Apples and Pears are ready to gather, but the latter are poor indeed, and I fear it is hopeless to expect that any kinds will be up to the usual standard this year, either as to size or flavour. As a rule, early Apples and Pears are very tender fleshed, and require the greatest care in gathering, as the least bruise soon develops into full decay. For the same reason they should be stored on the fruit room shelves in single layers only. Above all, see that none are gathered prematurely, or they will not ripen, but shrivel, or be sticky and hard. In none but the most favoured localities as to weather, can Figs be expected to ripen this season, but where there are any approaching maturity, they may be aided by full exposure, and keeping the wood thin and the foliage tied aside if it overlaps the fruit. Grapes certainly cannot ripen, and therefore the Vines should be denuded of their bunches, and the growth closely stopped back, in the hope of ripening the growth for another season. Note should now be taken of all trees that are growing too vigorously, and which will require root pruning, also of any that require assistance to increase root action by the addition of new soil and top dressings, and also of all new planting, and plants required for the same, so as to have all in readiness for planting next month—October being the best planting season for all kinds of hardy fruits.—W. W.

Extracts from my Diary.—September 15 to 21.

FLOWERS.—Putting in cuttings of Mrs. Pollock Pelargoniums. Picking decayed leaves off Pelargoniums. Tying shoots of Chrysanthemums. Taking up from north border and potting *Richardia æthiopica* and *Dicentra spectabilis* for forcing; and potting Stagshorn Pelargonium for winter blooming. Putting in a few cuttings of Poinsettias for late blooming in 3-in. pots. Putting in cuttings of *Iresine Herbsta* and *Heliotropes* for stock. Taking up roots of Violets with good balls of earth, and planting them in a cold pit previously prepared for them for winter blooming. Pricking herbaceous Calceolarias out of seed pots into pans. Staking and tying Carnations in pots, and moving them into cold houses. Potting Primulas for late blooming. Putting in cuttings of *Iresine Lindenii* for stock.

FRUIT.—Tying, stopping, and fertilising Melons. Gathering all Wyken Pippins; also Golden Noble Apples. Picking runners off newly-planted bed of Strawberries, and weeding them. Nailing mats on ripe Peaches to retard them. Getting in Perpetual Pine Strawberries for winter fruiting.

VEGETABLES.—Planting ground after Onions with Little Pixie Cabbages for spring use. Sorting Regent Potatoes, which are more liable to disease than some other sorts. Turning manure and leaves to induce fermentation. Making another plantation of Little Pixie Cabbage, and sowing Mustard and Cress. Planting Hammersmith Hardy Green, and All the Year Round Cabbage Lettuces. Digging ground on which have been Cauliflowers for Lettuces. Clearing old Cabbage for next crop. Putting night soil on ground and digging it in ready for planting Tripoli Onions. Pulling up old Cucumbers and preparing house for storing Pelargoniums for the winter. Planting Giant Rocca Onions on ground previously dressed with night soil and lime. Tying and stopping winter Cucumbers.—R. GILBERT, *Burghley*.

THE INDOOR GARDEN.

THE BRACKENS.

(PTERIS.)

THE Brakes or Brackens of this country are familiar to every one. Owing to their profusion they form a striking feature of our woods and moorlands, and, in company with other allied species, constitute dense thickets in the uncultivated parts of most tropical and all temperate regions. The genus, as at present constituted, contains over a hundred species, many of the varieties of which are richly crested and variegated. Their foliage presents every variation in division, from sagittate to quadripinnatifid. All the species are characterised by having their sori arranged in continuous marginal lines and by having evergreen foliage, with the exception of the common Brake (*P. aquilina*) and its varieties (*P. esculenta* and *P. caudata*), which are deciduous. They may for the most part be propagated freely from spores or by division of their rhizomes. Some of the choicer kinds are increased by means of bulblets, which they produce sparingly. The soil most suitable for the stronger-growing kinds is a mixture of light loam and good leaf-mould in equal proportions, with about one-fourth of the whole of river sand; the tenderer sorts do best in a soil composed of equal parts sandy peat and leaf-mould. It is important to drain well. Those with foliage of a coriaceous texture require a dry, airy situation, and all the temperate kinds are benefited by being grown in a cool frame during the summer months, with full exposure to sunlight. The kinds enumerated below are among the most useful of our cool Ferns:

Pteris umbrosa.—Few Ferns present such a majestic appearance as a well grown specimen of this plant. The lowest set of fronds, which are barren, form a kind of undergrowth, and screen from view the stipes of the taller ones. These fronds are tripartite, the upper division of which is cut down to a winged rachis into from four to seven pairs, and the two lateral divisions into from two to four pairs of linear-lanceolate pinnae, which are from 8 in. to 12 in. in length. Above these barren fronds are situated several which are intermediate in character between the barren and fertile fronds; and, above all, rise the entirely fertile ones, on tall, erect, round stipes. The pinnae of these are much narrower than the others and are gracefully reflexed. The whole plant is of a bright dark green,

and attains the height of 3 ft. or 4 ft. It is indispensable to the smallest collection. In distribution it is confined to tropical and temperate Australia.

P. cretica.—This plant is often sold as a substitute for the preceding, which in some respects it resembles. Its barren fronds are simply pinnate, and from 12 in. to 15 in. in length, with a wingless rachis, and the lowest pair of pinnae bipartite. The pinnae are opposite, lanceolate, wavy, and finely toothed. Those of the fertile pinnae are much narrower, with acuminate points. *P. cretica albolineata* is a variety of this plant, with a broad band of white down each pinna. This variety differs from the type also in the position of its barren fronds, which are prostrate, while those of the type ascend with the fertile ones. The type supplies an abundance of foliage for cutting, and the variety is a most useful decorative plant, and is always greatly in demand. They are natives of the tropical and sub-tropical regions of both Hemispheres.

P. serrulata.—This is a well-known Fern, and produces sporelings so abundantly as to become a common weed in many plant-houses. The varieties of this plant, such as *cristata*, *maxima cristata*, *angustata cristata*, *Applebyana*, *Dixonii*, and *Leyi*, exhibit some extremely elegant forms, the smallest of which are suitable for Wardian cases, and the larger for conservatory decoration and window plants. They are the easiest Ferns to manage, and some are grown on a large scale for market. The type is a native of China, but the varieties are of garden origin.

P. straminea.—This species has a very peculiar appearance, and emits a strong heavy odour when bruised. Its fronds, which, when mature, grow to about 15 in. or 18 in. in length, are triangular and pinnate, with the lowest pair of pinnae again divided, or only bearing two or four secondary pinnae on their lower side, the largest of which are nearest the rachis. The pinnae are lanceolate-acute, and cut into a series of acute serrated channelled segments, which stand nearly erect and face inwards. Well-grown plants of this are very attractive. It is a native of Chili, and is the *P. crispa* of gardens.

P. arguta.—This attains the height of from 2 ft. to 3 ft. when mature, and produces a quantity of light green spreading fronds, which are broadly triangular and tripinnate. The final segments of the barren fronds are oblong-obtuse, and finely toothed; those of the fertile fronds are linear-acute and entire. It is an attractive pot plant in a young state, and makes a noble specimen when fully developed. It is a native of Portugal and the Canary Islands.

P. tremula.—In appearance this comes near the preceding, but its fronds are of a darker green, and grow more erect, and its segments are narrower, and inserted farther apart. It grows rapidly from the sporeling state, and attains maturity in a few months. It is one of the best for a cool Fernery, and in a young state few Ferns can surpass it for table decoration. It is a native of New Zealand, Australia, and Norfolk Island.

P. tripartita.—This is a remarkably distinct species. The stipes, in a mature state, rise to the height of 3 ft. or 4 ft., bearing at their summit a spreading, umbrose, tripartite frond, the divisions of which are furnished with from eight to ten pairs and one terminal of lanceolate, deeply-lobed pinnae. The pinnae of the lower side of the lateral divisions are longer than those of the upper side. The stipes of the old fronds are chocolate-coloured, and form a pleasing contrast with the bright green of the foliage. This Fern is worthy of a conspicuous place in all Fern collections. It is widely distributed throughout the Tropics and warm temperate regions of the Old World, and prefers the temperature of an intermediate house, with very little shading.

P. quadriaurita.—With the exception of *P. aquilina*, this species has the widest distribution of any member of the genus, and is at the same time the most variable; it assumes every form of incision between pinnate, with linear, entire pinnae, and bipinnate, with deeply-pinnatifid pinnae. It also differs in size from a few inches in height to 6 ft. or more. The type has a pinnate frond, with several pairs of linear-lanceolate pinnae, which are cut down nearly to the rachis into linear-oblong lobes; the lowest pair of pinnae, and sometimes the next one or two pairs upwards bear one or two secondary pinnae on their lower side. The rachis, on the upper side, is usually armed with several short spines, each of which originates at a point where the veins leave the rachis. Among the varieties of this protean species are several worthy of special notice, such as *P. sulcata*, a very tall, elegant plant, with long, recurved pinnae, and a brown, polished rachis. *P. argyrea*, with a silvery-white band down each pinna, a most accommodating plant, thriving in any temperature between 50° and 80°, and in a young state one of the best for table decoration. *P. glaucovirens*, with low, arching fronds, and broad pinnae of a glaucous green colour. *P. nemoralis variegata*, a much smaller plant than *P. argyrea*, with a firmer texture, and with the upper surface irregularly variegated

with pinkish-white. *P. tricolor*, the most richly-coloured plant in the Fern family, having a ruby-coloured band down the centre of each pinna, enclosed within a band of white; and *P. rubrimeria*, with a bright, dark green frond, with the veins only coloured red. These variegated forms, with the exception of *P. argyrea*, require to be grown in a comparatively dry atmosphere, and near the glass, to develop their colours.

P. comans undulata.—This is one of the few Fiji Ferns that have become established in our gardens. Its fronds are from 1½ ft. to 2 ft. in length, with a partially winged rachis, and have similar divisions to *P. quadriaurita*, but with a less number of pinnae. The pinnae are ovate-oblong, and are cut down nearly to the rachis into a number of oblong-acute, wavy lobes, of which those inserted on the lower side of the pinnae are twice the length of those on the upper side. It also has the secondary pinnae on the lower side of the basal pinnae, as in the preceding. The habit of the plant is good, and the foliage is of an intensely dark green. It seems to thrive best in the stove.

P. macilentia.—The beauty of this plant lies in the lax arrangement of its divisions. The fronds are broadly-triangular in outline, and bipinnate as regards two-thirds of its length from the base; but the upper one-third consists of a terminal pinna and two or three pairs of pinnae below it, which are only pinnatifid. The pinnae are all placed distantly from each other on a slender, wiry rachis, and are furnished with from two to three pairs of distantly-placed, ovate, deeply-lobed pinnules, and a terminal one ending in an attenuated toothed point. The fronds are crowded together, and form an intricate dome of spray-like foliage, which is of a yellowish-green, and of a firm texture. It is a native of New Zealand, and at present it is very scarce. Those who decorate on a large scale will see in this a very desirable plant.

P. scaberula.—This is so common in gardens that a description would be here unnecessary, but as it is so often confounded with *Davallia Nova-Zelandica*, or *Aerophorus hispidus*, it may not be out of place to note down their main points of difference. When both are in character, *P. scaberula* is always the largest plant, with a rough, greenish, flexuous, zig-zag rachis, and hispid dull green foliage. *Davallia Nova-Zelandica* has a slender, wiry, smooth, bright, straight, or sometimes curved rachis, with bright, usually brownish-green foliage; should the specimens be in the sporiferous state, the character of the sori will suffice to distinguish them. *P. scaberula* is very useful for cutting, but if it be left in a dry place after being cut, it shrivels in less than an hour; whereas the *Davallia* would remain fresh under the same conditions for twelve hours or more. Both are New Zealand Ferns.

P. semipinnata.—The appearance of this Fern is both singular and ornamental. It produces a copious supply of foliage from a short creeping rhizome. The fronds are pinnate and from 1 ft. to 2 ft. in length, each of which has from four to six pairs of opposite, lateral pinnae, and a terminal one, which is deeply pinnatifid. The pinnae are deeply lobed on the lower side, and terminate in long, linear points; the upper half of the pinnae is reduced to a narrow wing. The lobes, which are serrated on the barren fronds, and entire on the fertile fronds, are linear-obtuse, and increase in length towards the main rachis. The stipes and rachises are chestnut-brown and polished, and the foliage is firm in texture and of a dark, shining green. It is generally a useful plant, either for cutting, decoration, or for pot culture. It is a native of the Himalaya, Japan, and the Philippines.

P. incisa.—This is synonymous with *Littobrochia vesperilionis*. It is characterised by having a creeping, laterally-branching rhizome, from which rise a number of closely-inserted, arching fronds, varying in length from 3 ft. to 6 ft., and also by having the pinnae, pinnules, and lobes inserted oppositely. The breadth of the lobes is very much reduced in the fertile fronds, a circumstance which, combined with the soft, glaucous green of the foliage, adds greatly to its attractiveness. It is a native of the Tropics of both Hemispheres. Too much shading debilitates this plant; it requires strong, diffused light of day, but not exposure to the direct rays of the sun.

P. heterophylla.—The young state of this plant somewhat resembles the Rock Brake (or Parsley Fern), but in the mature state its divisions are much larger as compared with that plant. It usually grows in tufts of one large and several small crowns, which together form a compact head, rarely exceeding 12 in. in height. The fronds are deltoid and tripinnate as regards the lower half; the upper half, above the lowest three pairs of pinnae, has the same cutting as the lowest pair of pinnae. The segments of the barren fronds are cuneate-ovate, with from five to seven forward-pointing teeth, while the segments of the fertile fronds are oblong and toothed only at the points. The foliage is rather succulent and of a bright green. It is exceedingly pretty and very rare in cultivation, though it is common in Bermuda and Jamaica.

P. longifolia.—Though an old inhabitant of our gardens, it rarely receives the attention it deserves; it is too often treated as a pot plant, whereas it is one of those subjects that delight to have free root action between the crevices of rockwork. Planted in such a position, with a full exposure to light, and in a temperature of from 50° to 70°, it will under favourable conditions produce a crown of foliage quite equal in grandeur to some of our finest Cycads. A fully developed frond usually measures 5 ft. in height, and 10 in. to 15 in. in breadth at the widest part, and partakes of the character of a leaf of *Cycas circinalis*, with the exception of having its terminal pinna extended beyond the rest, so as to form a caudal extremity. It is a native of the West Indies, and, in the Old World, of Spain, Lebanon, and the Himalaya, Tropical Africa, Polynesia, and South Australia.

C. M.

AUSTRALIAN TERRESTRIAL ORCHIDS.

SOME of these, such as *Diuris aurea*, *D. aurea maculata*, and *D. lilacina* (the species here figured), are very handsome and well deserving

Diuris lilacina. (Natural size.)

of attention. The two former produce yellow flowers, which in the case of *D. aurea maculata* are spotted with chocolate. *D. lilacina*, a very pretty species, bears on a spike from 12 in. to 18 in. in height a succession of flowers of a purplish-lilac tint, furnished with two long tails that give it a very grotesque appearance. *Pterostylis Baptisi* is another handsome species. Plants of the *Diuris* thrive well with us planted out in a cold frame in a compost of two-thirds sandy peat with one-third fibrous loam and produce a quantity of flowers.

F. H.

[The specimen from which the annexed engraving was prepared was sent to us by the New Plant and Bulb Company, Colchester, to the collection in whose nursery the above remarks refer.]

Todea superba.—That this beautiful Fern is deserving of more extensive cultivation than it appears to receive is apparent when one sees the amount of cold which it will endure and yet grow well. A short time since when looking through one of the principal London nurseries I was shown a plant of it in a most luxuriant state of health that had withstood several degrees of frost, as the house in which it was growing was not heated in any way.—J. C.

IXIAS, SPARAXIS, TRITONIAS, AND BABIANAS.

THE present time and for a month hence is the proper season to commence the pot culture of these highly ornamental and free-blooming Cape bulbs. Where a large supply of cut flowers is required during the months of April and May, few plants will be found more useful than these for meeting the demand; and their bright colours and graceful spikes are admirably adapted to give relief to a collection when arranged with flowers of a dwarfier character. The soil which we have found most suitable to them under pot culture is a moderately light, sandy loam, enriched with well-decayed cow manure and a slight addition of leaf-mould. Peaty soils should be avoided, as it is difficult to maintain the foliage in health through the flowering period in such soils. Next in importance to soil is perfect drainage; anything approaching stagnation at the roots is fatal to this class of plants. We have found 6-in. pots the best, placing about twelve bulbs in a pot with a dash of sand over them, and then covering them with $\frac{1}{2}$ in. of soil. After potting plunge them in ashes or Cocoa fibre in a cold frame. Very little water will be required for the first month after starting them, provided the plunging material is kept moist. As soon as the growths appear air must be given abundantly night and day whenever the thermometer is above the freezing point, otherwise they will soon run up spindly and be worthless. About the end of November they should be removed to a position close to the glass in a cool, airy house, and be carefully watched in order to see that they do not suffer from excessive dryness at the root after being removed from the plunging material. In this position they may remain with advantage till the beginning of March, when a house with a north aspect will be found the best, or they may be taken back to frames, in which they will flower freely, every pot throwing up from a score to three dozen spikes of bloom. After flowering, water should be gradually withheld, and the plants exposed to the full sun in order to ensure the bulbs getting well ripened, when they will prove serviceable the following season, and bloom equally well as imported bulbs.

Gunnelsbury Park.

J. ROBERTS.

THE FERNERY AT PENDELL COURT, BLETCHINGLEY.

THE recently constructed Fernery in Sir George Maeley's beautiful garden at Pendell Court is an excellent illustration of the manner in which a plant house should be arranged in the natural style, so as to produce a picturesque effect, and also display to the best advantage the beauty of exotic vegetation. It forms a striking contrast to the uniformity generally observed in conservatories, with the ordinary stages and benches covered with an array of pots, which, moreover, restrict the growth of the plants, so that their natural development is seldom attained. In this Fernery there is not a straight wall nor a level path, and nothing of an artificial structure except the roof, and the rafters of that are covered with Mossy growth, so as to afford as much as possible the appearance of a natural scene. The rocks with which the walls, banks, and mounds are constructed are tastefully arranged with studied effect, and no meaningless ups and downs which too often characterise a rockery are here observable. The mounds present a bold and rugged outline, around which wind the gracefully tortuous and undulating paths. By a skillful arrangement the light is subdued in some portions, so as to give the recesses the appearance of having greater depth than they really possess, and the illusion is very successful. A wonderful variety of plants is employed with which to embellish it, and all seem to succeed admirably under the treatment. At the time of our visit the walls were gay with flowering plants of *Gloxinia*, *Achimenes*, *Chirita sinensis*, and other Gesneraceous plants, the bright hues of which quite enlivened the sombre tints of the Ferns, Lycopods, &c. Numerous Tree Ferns judiciously disposed give an aspect of grandeur to the house, whilst on their stems twine such plants as the elegant *Scalaginella lavigata*, the fronds of which shine with a metallic lustre, quite unlike the majority of the other kinds. Orchids such as the beautiful *Cattleya citrina*, with its strange habit of growing downwards, are also quite at home fastened to the trunks of the Ferns. The huge stemless *Marattias*, *Angiopteris*, &c., spread their broad fronds over the smaller denizens of this miniature forest, and the Stag's-horn Ferns, Saw Ferns, Spleenworts, Maidenheads, &c., thrive with equal vigour. The Bird's-nest Fern is very effective with its broad, bright, green, erect fronds, under the shade of which, and in various other snug nooks, nestle the beautiful Filmy Ferns, such as *Todeas*, *Hymenophyllums*, *Trichomanes*, &c. *Amorphophallus Rivieri* and various other Aroids luxuriate capitably, as do also large numbers of Bromeliads, of which several were very brilliant, with their clusters of coral-like berries. *Gleichenias*, *Davallias*, and other elegant Ferns hang gracefully over the ledges of the rocks, and, intermixed with other plants, have a charming effect. One recess is devoted mainly to a

collection of indigenous Ferns, and though they do not possess such a tropical aspect as the stove and greenhouse kinds, they yet form a pleasing feature. Near to these was a plant of the hardy *Anthericum comosum* with variegated leaves, which harmonise well with the Ferns. The system of planting out is extensively practised in this garden, and it is evident that it is most conducive to luxuriant growth and profuse flowering, as the fine examples that have been shown from this garden bear ample proof.

W. G.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Propagation of Lapagerias.—"J. S. W.'s." avowal that he only wrote that which he was told about the Lapagerias at the Handsworth Nurseries does little towards clearing up the doubts which I expressed about the age of the plants described as having ten or more shoots each. I did not for a moment doubt the truth of what "J. S. W." stated respecting their size, but I do not believe that plants raised from eyes last autumn twelve-months, as reported, have now the number of shoots named. In this there appears to be some mistake; plants which have attained the size described (that is, the number of shoots) are in all probability not less than double the age named. They would indeed have done well if they had made as much progress in five years as that stated. When "J. S. W." wrote so confidently about Lapagerias being propagated as freely as Vines from eyes, I naturally supposed he meant what he expressed. He now says he did not mean eyes, but layers. But how can "J. S. W." reconcile these two statements? Vines are propagated from eyes, not from layers, except under very exceptional circumstances. The two—Vines and Lapagerias—are so different in character, both as to propagation and growth, that I do not see how any one acquainted with them can make a comparison between them. "J. S. W." asks why I gave directions not long since in "Gardening for the Week" for the management of plants from cuttings, "when, according to my own showing, I had proved the superior advantages of the layering system thirty years ago." Any one who refers to p. 166 (Feb. 22, this year) will see what I there said in reference to Lapagerias, and may judge for themselves whether I said anything in favour of propagating them from cuttings. I simply referred to what their after treatment should be, whether raised from layers or cuttings.—T. BAINES.

Mackaya bella.—This fine South African shrub, of which a coloured illustration was given in THE GARDEN (p. 150), is grown very successfully at Pendell Court, by Mr. Green, gardener to Sir G. Macleay, to whom we are indebted for the specimen from which our plate was prepared. The plant from which the spray was taken is over 6 ft. high and 4 ft. through, and forms an erect growing bushy shrub. It is planted out with other plants in a moderately warm greenhouse, in a well-drained border. The soil used is rich loam, with the addition of leaf-mould and well rotted manure. It is liberally supplied with water during the summer months, but water is almost entirely withheld in autumn and winter. By this means the growth made during summer is well ripened, with, of course, the aid of plenty of sunlight. In spring the plant is a mass of bloom, and the flowers, which are borne in long racemes, continue in beauty for a considerable time. Just before the flower buds appear it is necessary to give the soil a thorough watering, and the temperature of the house should range from 55° to 60°. After flowering the shoots are cut back moderately hard, and after that the summer treatment begins. Thus, by intelligent culture, one of the most beautiful shrubs, which has hitherto been considered a shy bloomer, is rendered one of the most desirable plants grown in warm greenhouses.—W. G.

Odontoglossums in America.—In reference to the remarks made by "C." (p. 79) on the treatment of *Odontoglossums*, I think the following remarks will go far to prove that it is by no means necessary to keep *Odontoglossums* so cold as is usually recommended. Here in America, where the outside temperature often exceeds 100° in the shade and 80° at night, one would be inclined to think that growing cool *Orchids* in America would be an impossibility; but, notwithstanding this, they do grow and flower freely, making good stout bulbs and shorter and more robust foliage than in England, doubtless owing to the abundance of air afforded them both day and night. The plants are removed about May to a cool house, which is half-span roofed with a north aspect, and here, by raising the shading about 1 ft. from the glass, giving abundance of air, and constant syringing both overhead and amongst the pots, we manage to keep the house about 7° colder than the outside temperature. Such species as *O. Alexandre*, *O. vexillarium*, *O. Andersonianum*, *O. nivenum*, *O. maculatum*, *O. cirrhosum*, &c., usually make two sets of flowering bulbs every year, and we have two instances this year of *O. Alexandre* and *O. Andersonianum* making a third

bulb, and in each case the bulbs have greatly increased in size. *O. Londesboroughanum* thrives with us in the Cattleya house, where the temperature sometimes reaches 110°, and where no shading, except a slight coat of paint, is used. *O. grande*, *O. Inslcayi*, and *O. Schliepenianum* succeed better with little or no shading and a drier atmosphere. All of them are wintered in a temperature from 50° to 55°, and to those not growing only sufficient water is given to keep the bulbs from shrivelling; but abundance is sprinkled about the paths, otherwise the atmosphere would be unbearable owing to the brisk firing necessarily resorted to. From experience I think *Odontoglossums* are kept too cold and wet in England, though I admit that they are grown and flowered exceedingly well in many places; but there are large plants here imported from England on which may now be found American and English-made bulbs, and it may be seen at a glance that those made in the higher temperature are certainly larger and more robust. I can scarcely recommend planting them out, though *O. grande* has been planted out here in numbers in a rich open border and it succeeded admirably.—F. GOLDRING, Albany, N. Y.

Acacia Riceana and its Treatment.—This fine plant has often been referred to in horticultural papers, and it deserves all that can be said in its favour, though it is somewhat strange that it should only have come in for notice within recent years, seeing that it has been such a long time in cultivation. In some few places plants of it of the size of trees are to be found, but such specimens are few. I am told, by those who are acquainted with it in its native country, that it is procumbent in habit, and covers the ground with its trailing shoots as with a network, and that it is much detested by travellers on horseback, as it entangles the horse's feet at every step, rendering travelling laborious and difficult. The habit of the plant makes it very accommodating in the matter of training, and a very fine conservatory specimen may be made of it. It is usually trained to the rafters, and very well its long pendent sprays look drooping from the roof; but it may also be trained as a standard in lofty conservatories, and if the branches are allowed to droop naturally in masses, the plant assumes a columnar shape, and looks more like a fountain of flower than anything else to which it can be compared. If desirable, it may also be trained in a formal shape. To give the plant bulk sooner, the branches may, indeed, be supported on hoops; but as it gets older such supports will not be required. A seedling plant should be planted in good soil, and the central limb trained to a straight stake till the desired height, and all side shoots should be allowed to fall into their natural position. In two or three years a plant so treated will form a very striking object when in flower. It need hardly be said that it should have a light and favourable position, in order that the shoots may flower freely. This *Acacia* may also be used effectively for draping walls. For such a purpose the leading limb need only be trained along the top of the wall, and in a year or two the drooping shoots will cover the wall from top to bottom. Glass screens and partitions may also be furnished in the same way. Of course, for such positions, the tree should be planted out in the bed, or in a brick compartment prepared for it, and filled with good sound loam chiefly, and well drained. Such plants do little good in pots. When planted out, growth is much more rapid; and *Acacia Riceana* is just such a plant as should be allowed to develop itself as freely and rapidly as possible, as, apart from its ornamental appearance, it is useful for cutting, and the long sprays are valuable for inserting in places where drooping subjects are suitable, and do just as well as plants grown for the purpose; the body of the vase being filled with something else.—J. S. W.

Frankincense.—The common Frankincense of commerce, also known as Gum Thus, is a resin which exudes from fissures in the bark of the Norway Spruce—*Abies excelsa*. When melted in hot water and strained, it constitutes Burgundy pitch. The turpentine obtained by making incisions in the trunk of a species of our southern Pines—*Pinus australis*—when old and hard, is also often called by that name; though commercially known as "scrape." The true Frankincense of the ancients, however, is the fragrant gum resin known in medicine as *Olibanum*, the product of certain species of trees of the genus *Boswellia*, which grow among the mountains of Central India, upon the Coromandel coast, and also in the interior of Arabia.—*Rural New Yorker*.

MR. J. R. WEST, late assistant forester at Longleat, has been appointed forester at Fonthill Gifford, Wilts, the property of Sir Michael Shaw Stewart.—MR. WILLIAM NICHOL, who has for upwards of twelve years been gardener at Drinkstone Park, near Bury St. Edmunds, has been appointed agent on Lady Gage's Hengrave estate, also near Bury St. Edmunds.—MR. GEORGE PALMER, gardener to Col. Tremayne, of Carclew, Perranar-Worthal, Cornwall, has been appointed gardener to T. H. Powell, Esq., of Drinkstone Park.

THE KITCHEN GARDEN.

ASPARAGUS CULTURE.

(Continued from p. 225.)

Unearthing.—This is the term given by the Argenteuil growers to the operation which consists in taking out the soil from the bottom of the hollows or trenches in which the Asparagus stools are planted and throwing it upon the mound from which it was taken. When first a plantation is made the intermediate mounds have a pretty rapid slope, that is to say, they form an angle of 45° with the perpendicular. It is plain, therefore, that the soil forming their sides will gradually tend to fill up the intervening hollows, either from the action of the rain or from the constant weedings with or without the use of the hoe. Commencing with the autumn immediately following the first planting we must begin to unearth, that is to say, to clear out of the trenches the soil which has fallen into them from the sides of the mounds, and also remove from above the stools a portion of that with which they were covered at the time they were planted, say to the depth of $1\frac{1}{2}$ in. or so, so that the action of the frost may open the soil and that the rain may penetrate and improve it, also that during the first fine days of spring the sun may warm the surface of the soil and penetrate as far as the stool. Under the old-fashioned system the contrary operation took place. The trenches were filled with manure and stable litter for fear that the action of the frost should kill the plants. This is an error which has luckily long been exploded. The Asparagus will never freeze as long as the stool is covered with a layer of soil of $1\frac{1}{4}$ in. to $1\frac{3}{4}$ in. in depth.

Earthing up the Mounds.—Earthing-up operations should be commenced at the beginning of March. This operation consists in taking out the soil which was thrown into the trenches at the end of the preceding autumn and restoring it to the sides of the mounds. Some growers divide this operation into two parts, one being performed in March and the other in April, so as not to interfere with the warming up of the earth by the solar rays, for when it is completed at one operation the heat penetrates the soil with much less rapidity and the growth of the plants is much retarded. A layer of fresh soil $\frac{1}{2}$ in. thick is also thrown into the trenches, so that the roots may be covered to a total depth of from 3 in. to $3\frac{1}{2}$ in. Treated in this way Asparagus will stand the drought of summer without harm. For earthing up the large flat or the narrow hoe is used.

Formation of the lesser Mounds over the Stools.—The formation of the lesser mounds covering the stools should be begun about the 25th of March in the climate of Paris, but in warmer localities about twelve or fifteen days before the first young heads begin to make their appearance. These lower mounds will vary in height according to the age of the plantation. The following measurements may be taken as being pretty near the mark: At three years from the first crop, from 5 in. to 6 in.; at four years, from 6 in. to 7 in.; at five years, from 7 in. to 8 in.; at six years, and for all the following years, from 8 in. to 9 in. These differences in the heights of the lower mounds are dependent on the size of the stool. The stronger the stool the greater the depth of earth above it that it will support, seeing that the larger and stronger the heads the more easily can they penetrate the superincumbent soil, whilst a young and comparatively weak shoot will become sickly during the process of slowly pushing itself through, besides which, it will most likely become so deformed as to be unfit for market. By properly earthing up we may obtain heads of the following lengths: third year, 9 in.; fifth year, 10 in.; sixth year, 11 in.; and all the other years from 11 in. to 12 in. For making the lesser

mounds we use the narrow or broad hoe, taking care to use fine open mould which has been well exposed to the atmosphere, so that the young heads may push through it easily. If it contains any stones they must be carefully sifted out and not allowed to remain in the plantation, for reasons already stated. We must also be careful not to allow any manure to remain in these lesser mounds. In order to gain an exact notion of the way in which these lesser mounds are formed, we have only to glance at fig. 6, where we have the section of an Asparagus plantation before these lower mounds have been formed. The stools are at the bottom of the hollows T T, and the upper mounds A A are at their greatest height, whilst after the operation of earthing up the lesser mounds has taken place, the aspect of the ground becomes completely

Fig. 6.—Asparagus trenches before earthing up.

changed, as seen in fig 7. The mounds A A (fig. 6) are lowered, their tops c c c being completely carried away, as shown in fig. 7, in order to fill up the trenches and form the lower mounds B B, covering up the Asparagus stools T T (fig. 7). It must be perfectly understood that the lesser mounds which earth up the stools are not continuous ridges like the upper ones A A (figs. 6 and 7), but form little isolated conical hillocks, like mole-hills, the centre of each being over the centre of each Asparagus stool. Consequently, B B (fig. 7) represents a series of separate mounds and not a continuous ridge running from one end of the trench to the other. Some cultivators recommend that these lower mounds should be made isolated one year and in the form of a continuous ridge the next. There is, however, no advantage in this; on the contrary, we think that there is a double inconvenience involved in this method, for not only is the labour of cultivation rendered much more difficult and irregular, but the stools do not gain so much benefit from the rain. It happens frequently that during the gathering in of the crop heavy rains set in, followed by great drought. In this case the mounds become excessively hard, and the heads find the greatest difficulty in penetrating the thick crust of their prison. Now is the time to use the three-pronged fork and stir up the earth

Fig. 7.—Asparagus trenches after earthing up.

to the depth of from 1 to $1\frac{1}{2}$ in. only, so as not to injure the young heads, which are just beginning to push their way through. Three such forkings are sufficient for each mound.

Gathering the Crop, Keeping, Packing for Market, and Transport.—The Asparagus cutter must know his business, otherwise he will do more harm than good by injuring the stools. In former times Asparagus cutters used a long knife curved at the point, the cutting edge of which was toothed like a saw or nicked like a scythe. This erroneous method has long since been abandoned, and the crop is gathered as follows: We must first of all clear away the soil which surrounds the head we are going to gather, either with

the fingers or else with the point of the knife used for cutting it. The knife is then thrust down so as almost to reach the root, taking care not to cut or bruise the neighbouring heads which have not yet pierced the soil. The head is seized between the knife and the thumb as near the root as possible, by pressing the blade of the knife firmly against its base, taking care not to bend or bruise the head in the middle. The head, being held firmly between the knife and the thumb, is gently pulled or twisted out and removed, the hole left by it is filled with soil by means of the cutting knife or the fingers, and the operation is finished. Care must be taken not to cut the head with the knife, which is only used as a lever and not as a cutting instrument. In order that Asparagus may be gathered in this manner, it must be grown on the Argenteuil system, otherwise the heads being hard and woody it will be found impossible to detach them easily from the parent stool. Where this method is carried out carefully it has a great advantage over the old-fashioned system of cutting with a saw-bladed knife, and we strongly recommend all growers to practise it. It is somewhat slower, it is true, but it has the great advantage of not wounding the heads surrounding those which are pulled up, as well as of separating the useless stump of each head from the stool, instead of allowing it to wither and rot. For this purpose we have invented a special instrument in the form of a large, flat, shallow spoon, which is very easy to use. The best time for gathering Asparagus is when it shows some 1½ in. to 2 in. above the ground. If it is gathered sooner than this there is a loss, in consequence of the heads not being sufficiently mature. If we defer it until later, the heads lose their proper flavour and hue, and become bitter in taste and green in colour; besides which it is only eatable throughout a portion of its length.

Keeping.—If we cannot use the gathered Asparagus at once, it must be carefully moved into a cellar specially devoted to the purpose. It must not be either washed or damped, and must be spread on the ground in the coolest and darkest part of the cellar out of reach of the light. Asparagus may be kept in this way for nearly a week, but it loses part of its flavour, becomes harder, and does not cook so well. If the crop is intended for market, it must be tied up into bundles, the size of which is regulated by the locality to which they are intended to be sent. At Argenteuil the bundles are generally from 6½ in. to 7½ in. in diameter in the middle, and from 4½ in. to 5½ in. in diameter at the head. To make the heads up into bundles, a small bench is used, to which is fixed at right angles a piece of board containing a hole of from 4½ in. to 5½ in. in diameter, and 1¾ in. deep, the hole being backed by another piece of board firmly screwed on. About 10 in. in front of this piece of board is another upright piece fixed parallel to it, and provided with a U-shaped hole. This upright piece slides backwards and forwards in a groove and may be fixed at any distance from the first upright piece by means of a thumb-screw. One of the sides of the U is hinged, so as to allow the workman to remove the bundle. The workman sits in front of the bundling bench, and turning it with the hole away from him and the U nearest to him, he chooses the best heads of Asparagus from a heap by his side, and places them in the U, allowing their tips to rest lightly in the stopped hole. If the Asparagus is flat he places it in such a way that the largest part is on the outside of the bundle. The medium-sized and smaller heads are placed in the centre. The heads are so adjusted in the hole that they are quite level. When the bundle is large enough a strip of Willow is passed round it about 4 in. from the top, and firmly tied, but, of course, without bruising the heads. Another strip of Willow is tied round the bundle about 4 in.

from the lower end. Any of the heads whose lower extremities project too far beyond the bottom of the bundle are cut off level, and the operation is finished. Crooked heads may, with care and gentleness, be bent perfectly straight. If they break during the operation the two pieces may be united by inserting a sliver of wood into one of the broken ends and then sticking it into the other. When the whole of the gathering has been made up into bundles, they are placed upright in tubs or tanks of water, which must completely cover them. They are left in this condition for several hours and are then washed with a long-haired brush, which is passed gently over them backwards and forwards. They are then drained for ten minutes or so and are ready to be sent to market.

Packing and Carriage.—Asparagus is sent to market in large, strongly-made baskets, which contain twenty or thirty bundles and even more. The bottom of the basket is lined with hay or straw as well as the sides, after which the Asparagus bundles are put in rows and pressed together sideways pretty firmly, so that they cannot shake about. A layer of straw is now placed, and another layer of Asparagus, and so on till the basket is nearly full, a thicker layer of hay or straw being placed on the top of all. Great care must be taken not to stint the amount of hay or straw used in lining the top, bottom, and sides of the basket, otherwise the tips of the heads will be knocked off and the Asparagus rendered unsaleable. The Asparagus grower who seeks to do a good trade must exercise great taste and judgment in preparing his merchandise for market. The first thing to be done is to place the largest and best looking heads on the outside of the bundle. Towards the end of the season, however, Early Asparagus becomes rather small; we must therefore have at hand a certain quantity of large heads of Late Asparagus, so as to be able to "dress" the bundles in a proper manner. The Asparagus grower, therefore, will do well to plant say a quarter or even a third of his ground with the large variety of Late Asparagus, for a few large heads placed in a bundle of small ones will often make it sell for double the amount which it would otherwise have fetched. GODEFROY-LEBEUF.

IMPROVED CABBAGES.

COMPLETE and comprehensive as is the article on garden and field Cabbages given in your number for August 16, there is yet one point to which little attention has been directed, I mean their culture. Cabbages, I fear, rank so low in the scale of vegetable productions with gardeners now-a-days that they never trouble themselves to enquire how or by whom any improvement in them is made. It may seem invidious to mention it, but I believe that the greatest improvement in the early Cabbages grown at the present day is due to cottagers who have taken pains to overcome their tendency to run to seed in spring instead of forming good-sized hearts. It is a well known fact to all who grow Cabbages that early and forward plants, or those that have attained the largest size during the autumn and winter, are the most likely to run to seed in the spring; hence the advisability of not sowing the seed too early in the preceding summer. For many years the period of sowing the main crop of spring Cabbages has been an important one with all cultivators, for if sown too early the crop is almost sure to run to seed in spring, and if too late, it is hopeless to look for very early Cabbages; and in order to aid in overcoming this difficulty it has been the aim of those who have endeavoured to improve the varieties of Cabbages to produce kinds which have the least tendency to run to seed in spring, and at the same time pass through the winter, be it ever so severe, of a good size.

Now this qualification in a Cabbage is not possessed by all the varieties that are offered by dealers, and a knowledge of the kind possessing this qualification is the point that determines good cultivation from the ordinary hap-hazard system with which so many are contented, amongst those who look with a certain amount of contempt on the Cabbage grower. Now, it must be confessed that the Cabbage has been much improved during the lifetime of the present race of growers. I can remember the time when it was not thought

proper in any part of England where I resided (and I have done so in half-a-dozen counties, and these often widely apart) to sow the main crop of spring Cabbages before the 12th of August, and I believe I am right in saying that the earlier class of growers did not sow them so early as even that. Abercrombie, I think, lays it down as a maxim that the 21st of August is the proper time. Now, thanks to those who have improved the Cabbage so much, the best varieties may be sown with safety a month before that time, and for the last thirty years or more I have been in the habit of sowing the first batch of spring Cabbages on or before the 20th of July. The variety I first had from a cottager, and it was but rarely that any of them run to seed in the spring; even last year, 1878, I sowed the same kind on July 15, along with two more varieties; in planting they accidentally got mixed, and I found this spring that only three or four out of about three hundred ran to seed, and whether these were of the original kind or of the others I could not tell; but I believe the cottager's old kind is the nearest proof against bolting, and consequently from it it is difficult to get seed; I, therefore, always go back to my old friend for a supply of seed, rather than trust to names of the highest repute. I cannot give the name of the variety as it is purely local, but I believe that it originally had a beginning in a market garden, where it may possibly be still grown. Its adaptability to stand the winter when of large size is a property that I have always admired in this Cabbage. The cultivation of the Cabbage has always been with me a favourite pursuit; a good bed of Cabbage affords us something to eat from almost every day in the year; but when I see it recommended to sow the main crop of early spring Cabbages as late as the end of August, I confess I have yet to learn how to get them fit for use early the following spring.

AN OLD GARDENER.

Potato Disease in North Hants.—Potatoes are very bad in this neighbourhood. I have grown several sorts this year, but none of them are exempt from disease. The first that showed it was Extra Early Vermont. This was on July 15th; then came Early Rose, Porter's Excelsior, Snowflake, Schoolmaster, Red Emperor, Myatt's Prolific, Paterson's Victoria, Grampian, Old Ashleaf, and Magnum Bonnm. The last did not become affected till August 13th. The worst I have as yet lifted is Red Emperor; out of six pecks I only got a quarter of a peck of good tubers. Poor sandy land has the best of it this season, also those sorts that were planted early. Since the beginning of the year up to the end of August we have had over 30 in. of rain.—J. CROOK.

French Breakfast Radishes.—After a long, trying winter like the past, when all kinds of green vegetables get scarce in spring, especially salading of most kinds, the utility of a good quick-growing Radish becomes apparent. After trying various sorts, I find none so useful and quick, as regards growth, as the French Breakfast. I made my first sowing of it in the open air in the end of February on a warm, south border. Three sorts were sown side by side, and from the French Breakfast I could draw good Radishes a week before either of the other sorts. This is a decided advantage. Another recommendation belonging to this variety is its ornamental appearance. I suppose one of the reasons why it is not more grown than it is, is its being a little dearer than some sorts.—J. C., *Farnboro*.

Tomatoes in the Open Air and under Glass.—The only chance of ripening a crop of Tomatoes in the open air this season is to keep the growth very thin and have all lateral and side shoots pinched back as soon as the requisite number of flowers are set for a crop. This will concentrate the whole strength into the swelling fruit and hasten their maturity, and it is better to have a small crop ripened well and quickly than, by permitting a greater development, to retard the whole. The main leaves should be left on for the present; by and by, when the fruits are ripening, the foliage may be thinned to let in the sunshine to give flavour and colour. But the time will—in fact, is—come when every establishment of any pretensions should have a Tomato house. They are more thought of now in many establishments than Cucumbers, and they are far more wholesome. But though a house for their special culture will be a necessity in a complete establishment, yet wherever there is a greenhouse Tomatoes may be had, for they will grow in pots, boxes, or in any simple contrivance where a peck of good soil can be laid; and they may also be utilised for covering the back walls of forcing houses. The best results, though, will be obtained in a light warm position, and if used to cover back walls it is best to plant in pots in rather poor soil, and feed with liquid manure when the fruits are set and the plants require more support. Last season there was a good deal of disease amongst Tomatoes in the open air, but this year up to the present time, although the plants are late, they are very clean and healthy in this neighbourhood.—E. H.

GARDEN DESTROYERS.

THE CABBAGE MOTH.

(HADENA BRASSICÆ.)

THERE are perhaps no insects which are so destructive in kitchen gardens as the caterpillars of this moth, and the flower gardens are by no means free from their intrusions. They appear to be almost omnivorous, as no plants seem to come amiss to them—Cabbages of all kinds, particularly Cauliflowers, the leaves of Turnips, Lettuces, Currant bushes, &c., and even the leaves of the Tobacco plant and scarlet Geranium. Mr. Curtis states that "he knows of no caterpillar which is a more general feeder." This insect is so very common that the amount of damage it occasions every year is very considerable, and gardeners who are not troubled with this pest are indeed fortunate. The caterpillars are not content with eating the outside leaves of Cabbages and Lettuces, but make their way into the very hearts of the plants, where they are tolerably safe from anything which we can do to molest them; still many may be collected by carefully searching the plants. If the heart of a plant is found to be attacked, it may as well be cut open at once and the caterpillars destroyed, for if left they will most certainly render it useless for food even if they do not actually kill it. As these caterpillars generally feed at night time, and when nearly full grown sometimes remain hidden under elods of earth, stone, &c., during the day, they are more likely to be found after dark if searched for with a lantern. Several methods are recommended by various writers for the destruc-

Hadena brassicæ.

Caterpillar of *Hadena brassicæ.*

tion of this insect, but I can scarcely think they can be of much use if the caterpillars are well hidden among the leaves, as I fear no fluid or powder would reach them there. Sprinkling lime over the plants and watering them lightly overhead a few hours afterwards, or watering with soap and water, is said to be very efficacious. Sowing the refuse of beaten hemp broadcast over the plants is said to cause the caterpillars to fall down dead within half-an-hour. The same writer suggests planting Hemp near Cabbages, or watering them overhead with an infusion of Hemp; another states that covering Cabbages with fronds of the common Brake Fern, or Elder leaves was very effectual; an hour after the leaves were placed in position not a caterpillar was to be seen. This insect is very common, and may be found in all parts of this country, and on the Continent as well, wherever Cabbages, &c., are cultivated. The moths only fly after dark, and may be found during the day resting on the stems of trees, on hedges, &c.; they are of such an inconspicuous colour that under ordinary circumstances it is not worth while to search for them with a view to their destruction. They make their first appearance in May or June, and those of the second generation may generally be found in August. They lay their eggs on the leaves of Cabbages and other plants, from which the caterpillars are soon hatched, and may be found during July, August, and September. They at once begin feeding on the leaves where they were hatched, and then eat their way into the very heart of the plant. They are extremely voracious, and two or three of them soon demolish a Cabbage or Cauliflower, and what they do not eat they spoil by their droppings.

Plants often do not in any way show signs of their presence, and they are not discovered until the plant is cut open and found to be worthless. They do not attain their full size for about a month, during which period they increase very rapidly in size and change their skins several times. Soon after they are fully grown they generally bury themselves in the earth and become chrysalides, frequently surrounding themselves with a rough shell of earth. Sometimes, however, they undergo their metamorphosis on the surface of the ground. The moths from these chrysalides emerge in August, and, after pairing, at once lay their eggs, the caterpillars from which bury themselves in the earth towards the end of autumn, covering themselves with a case of hardened earth in which they pass the winter; some changing at once into chrysalides, others not undergoing their change until the spring. When the beds in the kitchen garden are being prepared a sharp look-out should be kept for these chrysalides, which should always be destroyed. The Cabbage moth belongs to the family Noctuidæ and the genus *Hadenia*; by several authors it is, however, described under the name of *Mamestra brassicæ*. In THE GARDEN for the 14th of December, 1878, I have given an account and description of another member of this genus, *H. oleracea*, the pot herb moth, which much resembles the Cabbage moth; they may, however, easily be distinguished by comparing the descriptions together. The Cabbage moth is about $\frac{3}{4}$ in. long, and measures about $1\frac{3}{4}$ in. across the wings when extended. The general colour of the moth is brown of various shades, the head is small, the antennæ long and fine; the thorax is greyish-brown, with a tuft on either side, on which is a dark brown mark; the body is brownish. The upper wings are greyish-brown, with several darker wavy, narrow, transverse bands and lines; the upper margin bears several darker and lighter spots; near this margin and on the side of the centre nearer the tip of the wing is a somewhat ear-shaped lighter spot (parts of which are quite white) surrounded by a dark line; rather nearer the base than this spot is an almost round light spot; immediately below this is a squarish spot bordered on three sides by a thick dark line. Near the outer edge of the wing is a whitish zig-zag line, on the basal side of which is a lightish, clouded band. The lower wings are whitish-brown, and are somewhat darker towards the lower edge, the fringe of which is nearly white. The caterpillars when fully grown are about $1\frac{1}{2}$ in. long; when young they are generally green in colour, but afterwards they vary very much from greenish to nearly black with pinkish markings. Just above the feet is a yellowish longitudinal band. Each joint is marked with a rather oblique black line on either side of the centre of the back. The head is reddish, and the feet, which are placed on the first three, the sixth, seventh, eighth, ninth, and last joints, are greenish. The chrysalis is about $\frac{1}{10}$ of an inch long, and of a bright yellowish-red colour. G. S. S.

ANSWERS TO CORRESPONDENTS.

Hypnum Moss.—What kind of Moss is this? and where is it to be procured?—M. S. (Hypnum Moss, also known as Feather Moss, is the commonest of our native Mosses; indeed, it would be difficult to find any garden lawn or grassy bank without this Moss in some of its forms. It has creeping prostrate or ascending branched stems, clothed with minute scaly leaves, which are arranged spirally, and set so thickly as to overlap each other, like the leaves of a Juniper or an Arbor Vitæ. It grows most during cold and wet seasons, and is in its best condition in winter and early spring. The kinds most common on grass lawns are the Spreading Feather Moss (*H. squarrosum*), Amber Feather Moss (*H. purum*), and the Cypress Feather Moss (*H. cupressiforme*). In order to obtain large flakes of this Moss, it must be sought for in woods, copses, and on moist banks, where the above mentioned kinds and the Long Feather Moss (*H. prelongum*), the Velvety Feather Moss (*H. velutinum*), the Silky Feather Moss (*H. sericeum*), and the Tamarisk Feather Moss (*H. tamariscinum*) may frequently be found associated together. The Moss sold by the florists in small square bundles, dyed an unnatural green, is the Three-edged Feather Moss (*H. triquetrum*).—C. M.]

Olea fragrans.—Is this hardy enough to plant out of doors? We are about sixteen miles south of London, on the borders of Kent and Surrey, and about 600 feet above sea level.—M. G. [If your position is so favoured as to slope to the south or west, you may venture to plant *Olea fragrans* in an open situation, as it has proved sufficiently hardy to stand out unprotected for the last six winters, and withstood the unusual severity of last winter uninjured as a wall shrub near London; but if no protection can be afforded to ward off north or east winds, you will only succeed by treating it as a wall shrub. It should have grown for a considerable time in a cool temperature, and it ought to be no less than from five to six years old, and about from 3 ft. to 4 ft. high. The soil should be a light loam, with a dry sub-soil. The altitude named is rather favourable than otherwise.—C. M.]

Diseased Ferns.—*Anon.*—The premature decay of the frond of your Fern is owing to a diseased state of the roots, probably arising from overpotting or being kept too wet. The mouldiness on the ends of the fronds may be caused partly by the condition of the plant, and partly by a stagnant atmosphere. In order to revive it, place it in a light airy situation, and keep it moderately dry for a time. It is a stove Fern, and requires a temperature of from 65° to 70°.—C. M.

Plants for Winter Bedding.—Can any one tell me the best plants for bedding out in winter, so as to have a gay winter garden where a summer garden is seldom or never required? The aspect is south but rather exposed, in the county Meath, Ireland.—E. C. II. [For effective winter bedding no plants are so

suitable as small shrubs, and the variety of these available for the purpose has of late become so great that as bright a flower garden in winter as summer is only a financial matter. The plants in the following list all bear the yearly double removal—that is incidental to such winter bedding—well, viz., *Aucuba japonica*, *Aralia Sieboldi*, *Azara microphylla*, *Cotoneaster microphylla*, all the variegated *Euonymus*, *Erica herbacea carnea*, *Erica mediterranea alba*, variegated *Ivy*, especially a groundwork for formal growing shrubs such as *Juniperus*, *Cypripedium*, *Lawsoniana erecta*, and *Thuja aurea*. *Retinospora aurea*, *R. obtusa aurea*, *R. plumosa*, and *R. ericoides* are all of them effective winter bedders, as are also variegated *Hollies*, but they do not bear the constant removal well; they will, however, last good for three years. *Thujopsis borealis*, *Mahonia aquifolia*, *Pernettya mucronata*, *Andromeda floribunda*, and *Portugal Laurels* are all well suited for forming beds or masses. The following hardy carpeting and edging plants look well associated with shrubs, viz., *Ajuga reptans*, *Alyssum saxatile*, *Arabis lucida variegata*, *Antennaria tomentosa*, *Phlox verna*, *Cerastium arvense*, *Sedum glaucum*, *Lydlum, corsicum*, and *acra elegans*. *Herniaria glabra*, *Thymus aureus variegatus*, and *Thymus lanuginosus*. This list might be extended, but the above named are the best, and sufficient for any ordinary sized garden.—W. W. H.]

Auricula Insects.—An insect has attacked the roots of my Auriculas this season. The body is white and fat; the legs six and black. When turned on its back a curious proboscis-like appendage runs down from the head as far as the junction of the third pair of legs with the body. Its length is about $\frac{1}{16}$ th of an inch. It deposits a quantity of white material round the roots and rootlets exactly like white mould. The effects of its attacks are only to be detected by the colour of the leaves, which turn yellowish-green. The remedy I have resorted to is as follows: I take the plants out of the pots, shake all the soil from the roots, wash thoroughly in water, dust the roots affected with powdered charcoal, and repeat at once. What is the name of the insect? Is it a common pest of the Auricula? How can it be destroyed? What is the cause of its coming?—H. J. N. [1. Your Auriculas are attacked by one of the root-feeding aphides, probably *Forda myrmecaria*, which is often found feeding on the roots of various plants in pots, which it much injures by sucking the juices of their roots by the aid of its long proboscis or rostrum. 2. The plan you have adopted is very good. Try powdered Hellebore instead of charcoal, watering with decoctions of various leaves, such as Tobacco, Stramonium, Walnut, &c., or a solution of sulphate of iron has been much recommended. 3. As to the reason of the insect's appearance, themselves or their eggs were probably in the soil in which the plants were placed, as the insects are apterous, and unlikely to move much about.—G. S. S.]

Diseased Cucumber.—*Anon.*—We can see no fungus on the piece of Cucumber sent. Fungi often appear on Cucumbers when the latter are out of health, but there is no reason for supposing that in these instances the fungi are the cause of the ill-health; they merely make bad worse.—W. G. S.

Seeds in Melons Germinating.—On cutting open a Melon the other day the seeds were found to have germinated, and to have produced small plants, with roots and two leaves quite expanded. The Melon itself was excellent in flavour, and of medium size.—R. ROBBINS, *Rhylid Court, Upston on Severn*. [Cases of germination of this kind are not uncommon.]

Names of Plants.—*H. C.*—*Echinocactus Ottonis*, not rare. *H. Y.*—*Brugmansia (Datura) Knightii*. *S. J.*—1, *Symphandra pendula*; 2, *Rosa microphylla*. *E. D.*—*Wig-tree (Rhus Cotinus)*. *R. S.*—1, *Stipa pennata*; 2, *Dactylis glomerata variegata*; 3, *Panicum Crus-galli*; 4, *Cinna mexicana*. *Stove.*—*Tacsonia insignis*. *T. M.*—*Alchemilla arvensis*. *Scottish.*—Next week. *W. M. C.*—1, *Harpalum rigidum*; 2, *Coreopsis lanceolata*. *M. J.*—*Statice tatarica*. *Enquirer.*—1, *Rudbeckia Newmannii*; 2, *Cimicifuga racemosa*; 3, *Eryngium amethystinum*. *A. B.*—1, *Adiantum Farleyense*; 2, *Asplenium bulbiferum*; 3, *Nephridium molle*; 4, *Pteris cretica*. *C. M. D.*—We cannot undertake to name florists' flowers, which can only be done correctly by a specialist.

Cucumbers.—*Major.*—Not the Cucumber disease. They are merely suffering from being overcrowded, and from want of heat and air. Shorten and thin out the shoots, and top dress; and if firing is recommended, and they are kept well watered, they may recover.

Questions.

New Budding Knife.—Would some of your readers who have tried it say how they have succeeded in their use of Ward & Garrard's Improved Budding Knife. Speaking for myself I cannot make it work at all satisfactorily.—W. E. LAYTON, *Cranbourne, Windsor*.

Permanent Hedge.—I have 400 ft. of ordinary "pale and space" fencing round two sides of my garden at Enfield, and as it shows signs of decay I thought of planting a permanent hedge to take its place as it becomes useless. Will any of your correspondents kindly inform me the best quick-growing sort of hedge to plant to form a close boundary to take the place of the paling, and so as not to occupy too much room? Also, whether it is necessary to have a bank or ditch, as either would, of course, take up room.—FRANÇOIS.

Grapes.—Would any of your correspondents be kind enough to state the heaviest average crop of good Grapes, that is, weight of fruit from each square yard of training surface, that they have known to be taken from the same Vines for, say ten years or longer in succession, the crops being regular and good throughout.—J. S. W.

OBITUARY.

Jesse Allgrove, for over fifty years a faithful servant to Messrs. Osborn & Sons, at their Sunbury nursery, died on August 17 in his eightieth year. He has for many years been manager of the nursery, and was actively employed as such until within a few months of his death. His upright character and the interest he always took in his business gained for him the esteem and respect of his employers and of all who knew him.

Frost in Ireland.—We have already indications of winter. The thermometer this morning (Sept. 1) registered 30°, or 2° of frost. Everything is very backward; no signs of Peaches, Apricots, Nectarines, or Figs ripening out-of-doors. Apples and Pears very small. Potatoes very bad, and still getting worse.—J. CLEWS, *Headfort Gardens, Kells, Co. Meath*.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE "CURL" OR BLIGHT IN PEACH TREES.

FEW fruits excel in flavour a well-ripened Peach that has been taken from a south wall. You may grow larger, heavier, and finer looking fruit under glass, but, for flavour, no house-grown fruit can compete with one ripened out of doors. I take this to be a well known fact, and yet I every now and then meet with people who are induced to grow Peaches only in houses or under a glass-fronted wall, having given up trying to grow them in the open air through frequent failures. No doubt late frosts have much to answer for. It is very vexing to see a wall covered with blossom and then to find that some late sharp frost has blighted all one's hopes of a crop. But that is not the only evil with which a Peach grower has to contend. He may get a good set and be looking with much reason for a heavy crop, when, in May, he will find the leaves of his trees thicken, appear blistered, then curl up, and, if he examine one, he will find it loaded with insects. Presently the leaves perish, the tree makes no healthy wood, and never recovers. Sometimes it lingers with a sickly hue for a time, but the best thing to be done with it is to remove it in the autumn, and replace it by another tree. This evil then is far worse than a late sharp frost. But what is the cause of this evil? Can anything be done to remedy it? On these points I shall be glad to know the experience of others and I will now state mine.

First let me notice the causes of the "curl." A cold, high wind will produce it. This is proved by the absence of this pest in a well-ordered orchard house. But such winds do not affect all trees alike; some seem more delicate in constitution than others. I have two trees in my garden close to each other, the Early Alfred and Bellegarde. They have been treated alike; but the Bellegarde this spring had about a dozen blistered leaves on it, whilst the other had none. Then, again, soil has a great deal to do with the prevalence of this pest. Gravelly soil seems to favour it. I have seen trees completely killed by it on gravelly soil. Heathy soil, on the other hand, does not suit the Peach. I am acquainted with a grower who built a long fine wall and covered it with Peaches and Nectarines; rollers and blinds were fixed, but all to little or no purpose. The curl beat him, and he had the trees removed. I have another friend, living in Kent, where the soil is most suitable for fruit growing, but he, too, is annoyed by curl and almost out of heart. I have no knowledge of the effect of heavy soil on the Peach; but chalky loam seems to suit it. I live in the South Downs, and my garden contains four Peach trees—the Noblesse, the Early Alfred, the Bellegarde, and Stump the World. The Noblesse was never a healthy tree, and up to this time it continues unsightly; but the other three are full of vigour, and not a curled leaf is to be found on them. I ascribe this in a great measure to the way in which they were planted, and in some measure to their general treatment. Let me therefore describe this. At a radius of about 4 ft. from the place where the tree was to be planted, a semi-circle was drawn, and within this the earth was removed to a depth of 3 ft. or so. Then a barrowful of earth from a field adjoining was brought, and with this, after it had been deposited in the hole, a small quantity of decayed manure was mixed. This was then rammed firm. Upon this another barrowful of the same kind of earth and manure was placed and rammed; and this process was continued until the level of the adjoining ground was nearly reached. On this the tree was planted and the roots well covered. In spring this space was covered with good-sized flint stones, in order that the roots might be protected from the sun's rays. The trees grew vigorously, and Stump the World was obliged to be root-pruned. My trees being without "curl" may be ascribed in a great measure to this method of planting. If I had not been on a chalk soil I should have added about a peck of chalk, or somewhat more of old mortar to the compost in which the trees were planted. In May, as I have said, about a dozen or so of blistered leaves appeared on the Galande or Bellegarde, but when they were removed no more appeared, and we have not again been troubled.

What is the best cure for "curl"? As soon as it appears wash or syringe the trees well with Tobacco-water. If only a few leaves seem blistered pick them off; and if the repeated doses of Tobacco-water do not cure the "curl," I know of no better mode of procedure than to pull off the diseased leaves. Possibly the second leaves may be healthy and the trees recover, but if not, replace them. It is bad policy, especially in a small garden, to retain a sickly tree of any kind.

A. S.

PRUNING AND TRAINING SMALL FRUIT BUSHES.

THE pruning of such bushes as Gooseberries and Currants, &c., is not a difficult matter, from a gardener's point of view; but there are some—many, I might say—who do not understand it. These are mostly amateurs, who perhaps keep an odd man about the place, who fills his time up in the garden, where he is aided by his employer in his leisure from business, neither perhaps knowing much of gardening, and particularly little about pruning. Not long since, I saw in a pretty and otherwise well managed little garden, belonging to an amateur, a quarter of Gooseberries that had been pruned by a pair of hedge shears. They were, as may be expected, completely choked up with wood to the heart, and bore no fruit. Both Red and Black Currants were mangled in the same way, and with the same results, and the owner was in trouble about his bushes. In another case the owner had been advised to thin out the young wood well, and he had followed that advice to the extent of cutting every shoot back close to the old wood, which of course resulted in a crop of spray also. No doubt plenty of such examples could be found. Writers are not, as a rule, explicit enough, and in this paper I propose to give a few simple instructions on the subject that I hope will be understood.

GOOSEBERRIES.—It should be understood that the Gooseberry bears its fruit upon the shoots formed the previous year chiefly, and upon spurs. These spurs, however, amateurs and cottages need not trouble themselves about, nor try to produce them by any method of pruning; they will take care of themselves. It is the annual shoots that grow every summer, and which have to be pruned during winter, that they have alone to contend with. These bear the greatest portion of the crop, and the finest berries. Thirty or forty berries to a shoot 1 ft. long or so is common on good healthy bushes that have been kept open by pruning. Supposing we have a young bush to begin with, with a stem about 6 in. or 9 in. long, and a head of two or three branches, the first thing to be done, when it is planted, is to see that no shoots or buds are left on the stem, as these give rise to suckers which become troublesome in after years. Such buds should therefore be rubbed off whenever they appear, and only such branches left as proceed from the head of the plant. In planting a clear neck should be left above the surface of the soil, the better to keep it in order. The first year the young bush will produce perhaps several growths from each of the previous year's shoots. During the summer these might be reduced by disbudding; but that plan is seldom resorted to, and we need not stay to speak of it here. As soon as the leaves are off the bushes, pruning should be performed. Gooseberries start early into growth, and thus pruning should consequently be done early in winter. The operator should first examine the bush, and then proceed to divest first one limb of a portion of its young growths, and then the next, and so on till he has gone over the bush. The two principal objects to be kept in view are, an even balance among the branches—which will ensure a round and well-shaped bush—and an open centre. He should leave those shoots only that point outwards, and he should not leave too many, but thin them out well—till in fact the bush looks a mere skeleton to what it was before it was pruned. In a young tree he will probably find it best to leave the terminal shoot; to cut out one or two next to that, and leave the third or fourth one behind, nearer the centre, but pointing outwards. What he does cut away should be cut cleanly and smoothly off at the point of origin—that is, close to the old wood. If the least morsel of a spur be left, it will probably produce a thicket of useless shoots the following season, and it is these which choke up the tree and spoil it. Careless pruning in this way is the ruin of Gooseberry bushes. What shoots are preserved should mostly be left entire, unless it be when a strong one needs to be shortened back to preserve the balance. Sometimes, too, the points of Gooseberry shoots get rather attenuated and crooked near their extremities, and such points should also be cut off. These abortive points are oftener caused by the use of nets than anything else, which lie upon the bushes and interrupt growth. To sum the matter up concisely, pruning a Gooseberry bush properly consists in cutting clean away at least two thirds of the annual shoots and leaving the remainder entire, or nearly so, and all pointing away from the centre of the tree, which should be open like a shallow basin. As the bushes grow old, and the branches cease to extend at their extremities, it will be found necessary to cut them back or remove them altogether, to make room for more vigorous shoots, that push from near their base and take their place. Frequently gross shoots will push from the centre of the bush; but these should all be rubbed or cut out right at the bottom, leaving no buds, unless it be found necessary to preserve such as may be conveniently placed to fill up a gap created by the death or removal of old branches, which sometimes happens in the case of old Gooseberry bushes.

RED CURRANTS.—These require nearly the same treatment as Gooseberries. The bushes may also be grown with a single stem; but they are more apt to form a stool of roots in the end, from

which suckers spring, and form branches if allowed to remain. In their case single stems are not so important, as the Currant can be more easily managed and pruned than the Gooseberry. The fruit is mostly borne on the young shoots of the previous year; at pruning time, therefore, these should be well trimmed, cutting what are removed clean away. The terminal shoot on the branch is always left, and two or three below it, just according to need. Some shorten the shoots back to the length of from 4 in. to 6 in. and some leave them entire. When they are very strong it is perhaps the best plan to shorten them a bit; but in any case we like to leave 8 in. or 9 in. of wood. Leaving too little of the shoot is apt to force a greater growth of wood than is desirable; whereas where a good bit is left a leader only pushes, and fruit is borne on the remaining portion. The racemes of fruit on the young shoots are, as a rule, finer than those from spurs; it is therefore well to raise a good stock of it on the bush. Natural spurs are found in greater abundance also when the young shoots are left nearly entire, and these bear plentifully in after years and should not be removed. As the trees get old and the branches produce weak shoots near their extremities, they may be removed, and stronger young shoots from the bottom allowed to take their place. Old Currant bushes have a wonderful amount of vitality, and the stock may often be renewed or increased by dividing the bushes when they have formed a broad stool of roots. The main limbs may be pulled away separately with roots attached; and if planted in good rich soil, will form good bushes quickly, and bear good crops of fruit. This plan is advisable in emergencies; but young plants make the finest and healthiest bushes in the end, and a young stock from cuttings should therefore be raised occasionally.

BLACK CURRANTS.—These bear in the same way as the Red, but they do not bear cutting back, and should only be freely thinned; the more young shoots that can be left the better, if they are not crowded.

RASPBERRIES.—In amateurs' gardens these are often injured through want of knowledge of the habits and wants of the plants. Raspberries like a tolerably moist and deep soil, and one that is rather loose and light. Stiff soils that get hard and dry during summer are not suitable, but may be rendered so by the application of coal ashes and rotten vegetable manure, horse droppings or cow manure, applied liberally. A mixture of all these put together, and trenched and mixed in with the soil in autumn previous to planting, would suit well, and plenty should be given if the soil be stiff and tenacious. Afterwards the ground about the roots should not be disturbed by the spade or fork, but the surface of the soil for several feet out from the Raspberry stems should be thickly mulched with decayed stable manure, or, failing that, plenty of short Grass. Mulching is highly beneficial to the Raspberry in all soils, but particularly in dry hard soils that crack and get thirsty during dry weather. As to crops of fruit, everything depends on getting up a strong set of young canes annually. The fruit is borne on the canes or shoots that grow the year before, and every autumn these die, and should be cut away, and the young ones tied in their places. These young canes are, however, often forgotten or neglected during the bearing season, very often getting broken and injured by nets, and by persons gathering the fruit. They should be looked to carefully, and poor and needy ones, and such as grow out of place or distant from the old stool, should be pulled up. Six or eight strong shoots should be left at each stool, and about November they should be tied in a bundle to stakes, or, what is better, to a rail or piece of strong band stretched on stout stakes about 3 ft. from the ground, when the tie will catch the canes about the middle. In this way the canes form one straight line. It is not a good plan to tie Raspberry canes in too rigidly. They should have a little play at the top, and for this reason we prefer a line to a rail. At the same time the canes are tied in, the tops may be shortened back from 6 in. to 9 in. according to their strength. Raspberry plantations need not be often renewed. If treated well and manured, the same plantation will last for years, and go on producing fine canes and good crops of fruit.

J. S. W.

INFLUENCE OF THE STOCK UPON THE GRAFT.

At the June meeting of the State Pomological Society of Michigan an essay with this title was read by Mr. H. S. Tyler, which comes more directly to the point than anything I have before read or heard. I will premise by saying of Mr. Tyler, to those who do not know him, that he is one of our best posted men in the sciences of pomology and horticulture. Old enough to have made many experiments and to have noted their results, he needs here no backer to his word or his note. He claims to have noticed as early as 1849 great differences in the flavour, size, and colour of several of the popular varieties of Apples grown upon different trees. This led him to notice carefully the departure from the normal type of those top-grafted upon the trees that had already borne fruit, the character of which he had known, and he found, in most or all cases, that though the fruit of

the graft did not lose its identity, still there was more or less departure from the true type either in the form, flavour, size, colour, contour, or keeping qualities.

He also placed on exhibition at the above meeting Baldwin Apples from three different trees, one of the common shape and flesh, one grafted by himself from a perfect Baldwin upon a seedling that had borne a smallish, sour, high-coloured Apple, with often a red tinge through its breast; oblate in form and keeping very late. The Apples from this graft, though still Baldwins, as reluctantly decided by the best experts after cutting and tasting, partook largely of the form and habits of the natural fruit of the tree, and as late as the 24th of July instant I saw them at his house in good keeping condition showing the inside tinge and the other peculiarities of the natural fruit. The third specimen exhibited was from scions from the same tree as the last, set upon a tree that had borne sweet Apples; and though the departure from the parent stock was less marked than in the case of the other, still it was sufficient to create strong doubts of its origin. These three trees were all growing near together on the same soil and under the same culture.

The exhibition of these Apples reminded me of several peculiarities that I had formerly noticed in the products of different Apple trees of the same variety. In two cases of five trees each of the same variety, bought and planted at the same time and showing no marked difference in appearance, one of each kind bore fruit three or four years before the others. In another case a tree of Talman Sweet bore Apples regularly every alternate year, but of inferior size with generally a bluish upon one side, but unmistakably a Talman Sweet; and what was still further remarkable of this tree, though not bearing on this question, the tree was forked in two main branches, of equal size, one bearing one year and the other the next. I know nothing of the history of the tree except that, during the ten years that I owned and watched it, it never bore an Apple on either branch except on these alternate years, and then never failed. Pedigree in grains has already become a prominent and interesting subject, and there is no question in my mind that pedigree in fruits is of equal importance and practicability. It is to me quite evident that in the general method of raising fruit trees, especially the Apple, there is a fault that is having a deteriorating influence in their fruitfulness and in the changing of the quality of their fruit.

Mr. Tyler closes his essay as follows: "I will sum up my conclusions by premising that for success in attaining and holding a desired point of excellence in fruit, the stock must be known to be healthy, hardy, and productive, and of a kind either sweet or sour, adapted to the maintenance and perpetuity of those qualities of the kind which is sought to be maintained. Hence, my position develops the fact that promiscuous root or top grafting—unaided by design to continue all of the good qualities of the kind, but operated for the purpose of rapidly multiplying trees for the markets—will always prove disastrous to the best interests of the orchardist, and carry with it more or less disappointment, loss of time and money, instead of profit and pleasure."—*Rural New Yorker*.

Cob Nut Failure.—The Cob Nut occupies a large area of valuable land for some miles around Maidstone, and up to the last week or two promised to be about the most remunerative crop which market growers had, the Nuts being fairly plentiful and of good size. Lately, however, it has been rumoured that the crop is likely to be a failure, and I fear that the report is too true. I have examined some of the finest and best-kept bushes that it is possible to see—bushes which in ordinary seasons have produced from 40 lb. to 50 lb. of Nuts each, and on these it is difficult to find a sound Nut. Instead of a kernel, nothing is found but a mass of watery pulp; the husks are already looking sickly, and the Nuts will doubtless drop before the ordinary season for gathering. There can be little doubt that the wet sunless season has been the cause of this misfortune, and possibly various soils and situations may be differently affected. I find that Filberts are not so bad, but they are very little grown hereabouts in comparison with Cobs. During the last few years the latter have been largely planted, as they are both heavier and more regular croppers than Filberts; consequently, very few Filberts are planted now, and existing plantations of them are being intercropped with Cobs, and the old Filbert stools are being cut away gradually.—J. GROOM.

Damsons and Bullaces.—The best crops of the year around Maidstone are those of Damsons and Bullaces. They are grown mostly on the outsides of orchards and in hedgerows to break the wind from other trees, and in open and exposed positions where tender fruits do not succeed. The best variety is the Farleigh Prolific, Cluster, or Crittenden Damson, an extraordinary cropper and a very hardy kind. It bears its fruit in bunches and commences to crop well at a very early date. Its strong leading shoots should be kept shortened well in at the winter pruning, when the tree soon becomes

furnished with a dense mass of fruitful spurs. The fruit, which is of excellent flavour, is about the size of that of the old Damson. This variety is altogether a safe sort to plant in quantity. The Cheshire or Shropshire Damson is a strong-growing variety which bears large oval fruit. It has a strong upright growth, and is a good late sort, but not so prolific as the preceding. Shepherd's Bullace is largely grown near Maidstone, where it is now bearing fine crops. Its fruit is large, and makes excellent tarts and good preserves; in fact, thousands of sieves of it go to the preserving establishments as a substitute for Green Gages; and, coming in as it does after most of the Plums and soft fruits are over, it generally fetches a good price.—JAMES GROOM.

Transparent Gage Plum.—Amongst the few varieties of fruit that will produce crops in a season like the present Rivers's Transparent Gage Plum is worthy of mention. At Cheshunt pyramids of this variety are all carrying good crops. The fruit is smallish, and equal in quality to the old Transparent Gage. None of the other Gages are bearing any fruit worth naming under the same conditions. It is evidently a sort that well deserves extensive cultivation.—P. G.

Lord Suffield Apple.—A neighbour of mine has just gathered 17 lb. of fruit from a single bush tree of this variety that came from Rivers's nursery in October 1875. The fruit hung in clusters round the lower part of the tree. The largest Apples weighed 8 oz. and 9 oz. each. The same tree bore well last year.—C. G., *Addiscombe*.

Prince of Wales Raspberry.—We have this and the Fastoff planted in lines under exactly similar conditions, and the annual growth of the Prince of Wales is quite double the height and strength of that of the Fastoff, and they have borne a crop in proportion to their vigour.—J. GROOM, *Linton*.

Green Chisel Pear.—This sweet hardy Pear deserves all the attention that "B." claims for it (p. 239). This season, when most other Pears are hardly recognisable in the north of England, the Green Chisel is bearing a fair crop of marketable fruit. About Stokesley it is planted against walls, and I observe that it is good on a west aspect. I am sure that on walls hereabouts it would be far more profitable than many of the large sorts of Pears which so seldom come to maturity in Cleveland. The fault of the Chisel is the production of too many fruit. This should be corrected by thinning out the spurs at pruning time. On the terminal cluster of a young branch on a standard Chisel Pear, I counted the other day forty-one fair-sized Pears.—C. McDONALD.

THE FLOWER GARDEN.

THE POLYANTHUS.

THOSE who intend to grow the old Gold-laced Polyanthus would do well to procure plants of it as soon as possible after September 1, that being a very good time to repot them, or to lift the plants from the open border to pot for spring flowering. The Polyanthus is now grown for exhibition in the north of England, the Midland Counties, and in the neighbourhood of London. As far as the cultural requirements are concerned, it does not matter whether the plants are needed for exhibition or not. They are so easily grown, and the expenses attending their culture are so small, that the humblest amateur may compete on equal terms with cultivators on a large scale. When the plants are lifted from the open ground, each of them must be broken up into single crowns, which should be potted separately into 5-in. pots, and, if small, 4-in. pots will be sufficiently large. Good fibrous, moderately-clayey loam is the best potting material; it ought to be enriched with about a fourth part of rotten manure and kept open by means of a little sharp sand and leaf-mould. Pot rather firmly. When potted, place the plants in a cold frame, keeping the lights over them for a few days until they are well established. If a frame is not available, they may be placed out of doors and shaded for a few days; the attention required is simply never allowing the mould in the pots to become too dry, even in the dark days of midwinter. It has been stated that when the flower trusses appear all should be removed except one if the plants are to be exhibited; but the reasons advanced for such a practice are not very satisfactory. It is a good rule to allow as many trusses or flowers to remain on a plant as it will bring to a state of perfection without injuring it. A Polyanthus grown in a 4-in. or 5-in. pot will produce many perfectly developed trusses, and if all of them except one were removed the solitary truss left would not be thereby improved. I have noticed the northern exhibitors staging their Polyanthuses—single plants in the centres of 7-in. pots—with all the trusses removed but one. Now which is

the best example of cultural ability—that just alluded to or a plant in a much smaller pot bearing four or five trusses? The case is very different as regards the finer varieties of Auriculas, for unless these have double crowns it is but seldom that a plant produces as many as two good trusses. As a rule one is enough and all ought to be removed but that one. The markings on the Gold-laced Polyanthuses are very beautiful; the lacing is of various tints of yellow, and the ground colour of different shades of maroon and red.

The following are the properties of a Gold-laced Polyanthus: It should have healthy, well-formed foliage; the stem should be strong and elastic, from 4 in. to 7 in. high; the footstalks of the pips should be stiff, and so proportioned as to length that all the pips may have room to show themselves without over-lapping, and they should not be less than seven in number; the pip should be large, quite round, perfectly smooth at the edges, and flat; the tube should be round, clear yellow, and well filled with anthers; the ground colour should be bright, without any shading; the edging, which should be clear yellow, should go through the division of each limb down to the eye. The nearer any new flowers come to these points the more highly they are esteemed.

The late Mr. John Edwards gives the following list of Polyanthuses in the "National Garden Almanack" for 1853, and the only recently raised flowers that can be added to it are Cheshire Favourite and Smith's Duke of Wellington. His list contains Alexander (Pearson), Bang Europe (Nicholson), Beauty of England (Mand), Defiance (Fletcher), Exile (Crownshaw), Earl of Lincoln (Hufton), George the Fourth (Buck), King (Nicholson), Kingfisher (Addis), Lord John Russell (Clegg), Princess Royal (Collins), Royal Sovereign (Gibbons). In addition to the above fourteen varieties there is a very fine dark variety named Black and Gold; nor should Bullock's Lancer and President (Hilton) be omitted.

Every grower of Polyanthuses should also be a raiser of seedlings. "Hope springs eternal in the human breast" says the poet, and it is this which animates the seedling raiser. Certain it is that great interest attaches to the whole process of selecting the varieties for pollen and seed bearers, watching the growth of the seed-pods, sowing the ripe seeds, and looking for the germination of the plants. Then comes the pricking them off when large enough to handle; planting them out into the beds in which they are to flower in rich soil about August; and tending them well and carefully until the flowers open in spring. The old growers used to select a well-marked, "pin-eyed" flower for the seed-bearing parent, that is, one that has the stigmas protruding from the mouth of the tube. The pollen from a first-class variety should be applied to this, and maroon grounds should be crossed with flowers of the same colour, and red grounds with red.

J. DOUGLAS.

THE AURICULA APHIS.

WILL you allow me, as one who can unhappily write with a too sure practical experience, to advert to this to me very painful subject. I had about four years ago a very large and choice collection of Auriculas; no amateur at that time in the southern counties had anything like so extensive a one, and I was not a little proud of my George Lightbody's, Beauty's, and other first-rate varieties. Shortly after this I noticed something wrong with my collection; plants began to have a very settled, immovable look, neither growing nor dying, but standing still; this was in the winter. I examined one or two, but found nothing but what then seemed to me the filament or mycelium of some fungus. I had never heard of the woolly aphid. On top-dressing I found that there was around some of the collars a collection of fluffy stuff, and by this time Mr. Horner had referred to it in the *Florist*, and Mr. Llewellyn, of Ynisgerwyn, had also noticed its presence. I had then to turn out all my collection, to wash the plants, and repot, losing, of course, all hope of exhibiting. One of my plants was sent up to the Scientific Committee of the Royal Horticultural Society, when one of its members proclaimed the white substance to be the mycelium of a fungus, another that it was an insect, similar in character to the American Blight. The late Mr. Andrew Murray asked me to send him a plant, but just at that time Mr. Llewellyn forwarded him one. All doubt was set at rest. The insect was found and described by Mr. Murray in the *Gardeners' Chronicle*, with his well-known accuracy and minuteness. It was declared to be a new insect, and strangely enough had appeared at the same time in many collections in different parts of the country. I had hoped that I had got rid of it, but alas, in the autumn I found it as virulent as ever. I had to repot, this being done twice in that year. Last year I again found it very strong. I had recourse to all sorts of things. I tried Tobacco and Gishurst, soft-soap and sulphur, and thought if my Auriculas survived this they could not be the very fastidious plants they were said to be; they did survive, and so did the aphid. I talked the matter over with friends, and amongst others with

Mr. Llewellyn; he advised me to try paraffin, and I have been fairly successful with it. A teaspoonful to a quart of water is the proportion I use, putting it into a quart bottle and then shaking violently, and, before the oil has time to separate, pouring it on the soil of the plant infected. I find that I still have it, although not to anything like the extent I had. Mr. Llewellyn also tells me he has some of it still, and this will be I think a sufficient answer to the remark of one of your correspondents that it is easily got rid of; it is most difficult to eradicate.

It is a mistake to suppose that the insect is not winged. I believe the males are uniformly so and the females sometimes; but, independently of this, the curious fluffy substance which surrounds the body is peculiarly adapted for carrying them to a distance, acting as the down of certain seeds—as the Thistle—for this purpose. I do not think that they are contained in the soil; at least, I know in my own case that when I detected them and imagined that they must be in the soil, I procured all the materials of my compost purposely from a distance, and yet they re-appeared; and, indeed, with me it seems that either I must abandon the culture of my favourite flower, or else keep a constant watchfulness over every plant. I have found what appears to me (though I have not examined it scientifically) identically the same pest on the roots of Lettuces, Sow Thistles, &c., in my garden, so that even if I get rid of them on my Auriculas I have no safety; they may any day come on the plants from some other source. By outward examination of the plants, and by the use of paraffin, I hope to keep the evil in check; but my real pleasure in my collection is gone. It is a constant source of anxiety, but yet I cannot give it up. I ought to have been amongst the exhibitors at the National Society for the last three years, but have been completely put out of the fight by this horrible pest.

My strong advice to your correspondent "H. J. N." is not to despise your enemy; do not heed those who pooh-pooh it! Before you repeat try the paraffin; or if you have already repotted all, watch for it. Turn out the pots on the hand, so as not to disturb the earth, and if you see it on the outside, or detect a slight white cloud on the inside of the pot, rub off all that you can, and then try the paraffin as I have advised above.

It is one of those mysterious attacks to which plants are subjected, for which no reason can be given. I do not think that it was ever known to our older florists; at least, in a treatise I have upon Auriculas I find no reference to the aphid, except the green one affecting the leaves, and I fear that it is one of those persistent foes which, like the American blight, require the most constant vigilance, but which may by that vigilance be kept under, if not got rid of altogether.

DELTA.

CLEMATISES AT WOKING.

THESE are now in great beauty and well worth seeing. Since the advent of C. Jackmanni, so many fine varieties have been raised that intending purchasers often experience a difficulty in making a selection. However minute and faithful the descriptions in trade catalogues may be, it must be admitted that they often fail to convey a true idea of the worth of a plant. I would therefore advise that a personal inspection of some such collection as that at Woking be made, where may be found the most meritorious and well proved kinds, not only in a high state of development, but so arranged that their various merits may be easily compared. Many of your readers may not, however, be able to make the personal inspection here recommended; I have therefore in their behalf made a note of the most ornamental and distinct varieties now flowering in Messrs. Jackman's trial ground, any of which may be relied upon to give the greatest satisfaction. Individual tastes differ, but in the selection here given representatives of the various shades of colour which prevail in this family of flowering plants will be found. The kinds enumerated are also all remarkable for distinctness and the fine effect which they produce when grown into large specimens. In the first place I would advise those who wish for one Clematis only to procure Jackmanni. Take it all in all, this variety is not to be surpassed for general decorative purposes; it is a profuse flowerer, free grower, and the intense purple hue of the flowers renders it a strikingly ornamental subject for the flower garden. It is equally beautiful either allowed to ramble freely over trellis work, trained to an old tree stump, or pegged down in beds in the flower garden. It is still one of the most effective kinds in the Woking collection. For a complete contrast to the foregoing, *Lanuginosa nivea* may be chosen, the flowers of which are pure white, and produced very freely. *Lanuginosa candida* is also a highly recommendable white variety, the individual flowers of which are fine, and are produced in very considerable profusion. For bedding purposes this variety proves very useful. *Velutina purpurea* is a complete contrast to the last-named varieties; the flowers are of a blackish mulberry tint, thus imparting to it a very distinct appearance. It is a hand-

some effective variety, and one which should be in every collection. Mrs. James Bateman is a pleasing variety, with lavender-blue flowers, and is highly recommended for forcing purposes. Another fine blue is Lady Bovill, one of the most profuse bloomers in cultivation. Thomas Moore is a very handsome variety with violet flowers, to which an exceptional development of white stamens lends additional interest. Lady Caroline Neville is a most beautiful kind; the flowers are French white with mauve bars. This is one of the most chaste varieties in cultivation, and should be added to every collection. Otto Frœbel is also a fine greyish-white kind, distinguished by the exceptional size of the flowers. A very distinct—although, in comparison with the above-named kinds, a small-flowered—variety is *Viticella rubra grandiflora*. The flowers are of a bright claret-red, and, as seen growing amongst the various shades of blue, purple, and white, it forms to them a very pleasing contrast. In a collection of a dozen varieties I should certainly include this one.

Rubro-cœrulea and rubro-violacea may also be mentioned as two very effective kinds. Those who would like half-a-dozen distinct and effective varieties would find the following to answer their purpose: Jackmanni, Lady Bovill, *velutina purpurea*, *lanuginosa candida*, Lady Caroline Neville, and rubro-cœrulea. These six varieties will suffice to produce a blaze of beauty the summer and autumn through. The great advantage which Clematisses enjoy over flowering plants generally is their ability of bearing with indifference the vicissitudes of an English summer. Continuous heavy rains do not appear to sensibly affect them; on the contrary, the excess of moisture at the roots seems to impart additional vigour to the plants. Many flower gardeners are now beginning to think that it would be better to rely more upon those plants which are certain to produce good effects than to depend upon such as can only display their capabilities in a fine summer. The experience of this season has proved that whilst Pelargoniums, &c., have failed in an unsatisfactory manner, and many other bedding plants have dwindled entirely away, the Clematis has afforded a glorious display of bloom the whole summer through. It would therefore I think be well to introduce this plant more freely into our garden arrangements, allowing it to take the place of a portion of our so-called bedding plants. Much of the labour of propagating and the expense of wintering would thus be obviated, and the grower would not feel so severely as is now the case, when so many tender plants are used, the effects of an inclement season.

The mode of training adopted by Messrs. Jackman is very simple. Stout posts about 4 ft. or 5 ft. high are inserted in the soil, around which the plants climb, completely clothing them, and developing into a dense mass of bloom at their summits. Specimens thus grown are also to be seen at intervals amongst the ordinary nursery stock, thus affording an idea of the way in which the Clematis may be employed in shrubberies and in the wild garden. In some instances the plants are trained over stout branches put together in the form of an inverted basket. This form of training is also very effective, and could be carried out in many situations where the standard form would not be admissible. Beautiful and effective as is the Clematis when thus treated, I must own to a predilection for a more unrestrained development. The Clematis is *par excellence* a climber of a very vigorous—and, in many instances an extremely hardy—description. I should therefore have much liked to see its capabilities tested in this direction. I would wish to see it rambling unrestrainedly in well-chosen, natural positions, where it would undoubtedly attain a luxuriance of development hardly attainable by a more dwarfed system of culture.

JOHN CORNHILL.

B. fl. et.

Primroses.—From "An Old Gardener's" reminiscences of the Primroses (p. 234) it would appear that few of them are of modern origin. The latest addition, a pretty mauve-coloured one, introduced from the Continent last year, seems to be one that is likely to prove a great favourite. Curiously enough, within the past few years M. Lemoine, of Nancy, has introduced some remarkably double forms of the Alpine Auricula, originated, doubtless, in some process of careful selection and seeding, and it is just possible that the double Primroses originated in the same way. I do not know what may be the experience of others; but, so far, all my endeavours to secure genuine hybrids from diverse species of the Primula family have failed, and I do not think that—except from our own indigenous species, *P. acanthis* and *P. veris*—there yet exist any garden Primrose hybrids. Polyanthus and Primula amoena have refused to cross; so also have *P. japonica* and the latter; but there is perhaps more actual affinity between *acanthis* and *veris* than between any other two species. Mr. Clapham, of Scarborough, has been busy during the past few years in making crosses between the best garden forms of Polyanthus and Primrose, and I have now sown some seed of his latest crosses that may produce some good results. The rich-

coloured single Primroses have attained an excellence both in form and colour that it will be difficult to beat. They are much more robust than are the high-coloured double ones, and in that respect only are worthy of a wider cultivation.—A. D.

THE RHETIAN WALLFLOWER. (*ERYSIMUM RHETICUM*.)

THE annexed engraving represents a pretty mountain flower which, though rarely to be met with in cultivation, is a common Alpine in Rætia and the neighbouring districts, where in early summer broad dense-tufted masses of it are aglow with pretty clear yellow blossoms. It is by no means a newly-introduced plant to our gardens, as it has been in cultivation for upwards of half a century. It is somewhat similar to the Dwarf Alpine Wallflower (*E. pumilum*) of the Swiss mountains, which is a perfect gem, rarely exceeding 3 in.

Erysimum rheticum.

in height, and the dense tufts formed by it are studded with bright lemon-coloured blossoms, which are large compared with the size of the plant. The Rhetian kind bears a resemblance also to the Lance-leaved Wallflower (*E. lanceolatum*), a common European plant which has major and minor varieties, neither of which, however, is so desirable as the kind under notice. *E. canescens*, a South European species with yellow, scentless flowers, is also a neat-growing Alpine, and so is *E. rupestre*, than which few plants are more to be desired for adorning rockwork. All of them are easy plants to grow, and they all delight in gritty soil in a well-drained and sunny position on the rockery. W. G.

ELLACOMBE'S YUCCA.

As the foster father of such a lovely plant as the *Yucca tenuifolia* (see p. 214), of Haworth's "Suppl. Plant Succ.," p. 34,* Mr. Ellacombe certainly, as it appears to my mind, deserves to be popularly credited with this plant by all who grow and love hardy evergreen plants. To settle the matter of botanical nomenclature, I would suggest that Mr. Osborn send good specimens of the flower-spike and leaves to Mr. Baker, Kew, and then if distinct,

* Haworth under "habitat" says "ex Malta accepit Dom. Loddiges, A. D. 1817: folia in nostris (forte junioribus) 4-5 lineas lata." Haworth does not appear to have seen the flowers even, and as to the foliage of Ellacombe's *Yucca* being "4-5 lines broad," it is ridiculously under the mark, even for a weakly young plant, and he is careful enough to say his was strong.

as I hope it may be, let it be definitely fixed once and for all. Pray let no more be said in repudiation of such a noble plant, but let it be known as Ellacombe's *Yucca* by all those who fail to appreciate the subtleties and urgent necessities of holding firm as Medean law to the priority of Latin names and descriptions. That this particular plant should be so known is all the more desirable since Mr. Ellacombe has always shown himself friendly to the genus, a fact to which past numbers of THE GARDEN attest, as he was also to Daffodils, Lilies, and a whole host of other lovely hardy flowers at a time when they were "under a cloud." That was in the "dark ages" of hardy plant culture, however, and now all that is changed, and our great-grandmothers' favourites hold their own in the gardens of many "Lady Corisandes," just as the elegant furniture of the "Chippendale" period, and pretty bijouterie of the "good old times" do in their drawing-rooms. As it is, this fine plant has already been referred to more than once in THE GARDEN as *Y. Ellacombei*, as *Y. tortulosa*, as *Y. tenuifolia*, and as *Y. Ellacombei* var. *tortulosa*; now the plant is in bloom pray let Mr. Baker have flowers, and so settle this question, but if distinct, then *Y. Ellacombei* is, of course, the fittest name to apply to it.

I remember once or twice having seen a large plant in the Fulham nursery, perhaps the offspring of the original, which Mr. Ellacombe received from the old Hackney collection of the Loddiges nearly half a century ago, and the brilliance of its crimson-brown buds, as seen in the early morning sunshine, impressed me as being most beautiful. No other *Yucca* ever pleased me so much—no, not even the Mexican *Y. baccata*, with its great, erect clusters of golden Banana-like fruit, and I shall one day write as polite a note as it is possible for me to do to my friend Mr. Osborn, asking him to send a small sucker or offset of his fine old specimen to a fine old garden wherein *Yuccas* generally "do" exceptionally well, and where at the present time *Y. gloriosa*, *Y. recurvata*, *Y. flaccida*, *Y. filamentosa*, and one or two others, are very ornamental, their spires of snowy bells being backed by Hollies and other dark-foliaged evergreens, by which their white flowers are considerably enhanced in effect, and particularly at dusk; then, indeed, our *Yuccas* and the lovely *Ilyacinthus candicans* are most beautiful. B.

—Mr. Osborn (p. 236) will find the name *Y. tortulata* in "Baker's Monograph," No. 29; but since that has been published it has been figured as a distinct species (?) in Refug. Botan., 317, and as a sub-variety of *Y. variafolia* in Engelmann's Monograph. My own idea now is that it is a hybrid between *Y. recurvifolia* (which it resembles in the leaves), and *Y. superba* (from which it would have acquired the red tinge in the flowers). But whatever its origin it is one of the handsomest of the genus; and the name, being recorded by such authorities as Baker, Wilson Saunders, and Engelmann, may stand till a better is found. To those who grow *Yuccas* I may recommend *Y. orchoides* (Bot. Mag., t. 6316). It is now in flower here, and is very distinct from all the other species in that the flowers are not pendulous and bell-shaped, but are quite stellate. It is, I believe, a scarce plant.—H. N. ELLACOMBE, *Bitton Vicarage*.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Coleus Hendersoni.—This is a truly fine addition to this useful family of plants. Its leaves individually are very large and highly coloured, and the habit of the plant is all that can be desired. Those who have to keep up a supply of fine foliaged plants during the summer months should grow this *Coleus*, both for room and conservatory decoration. It is so easily propagated that there is no difficulty in maintaining a supply of fresh well coloured plants the whole summer through. They are very effective, and may often be used in situations where valuable plants would be liable to sustain injury. At housing time one or two good plants of each variety placed in an intermediate house, will, if placed in a brisk heat in spring, furnish plenty of stock for the ensuing season. There is no need to take up room during the winter with cuttings, as those struck in the early months of the year will generally grow away more freely than those struck in the autumn.—J. CORNHILL.

Tuberous Begonias from Seed.—That these will succeed out-of-doors in ordinary summers is placed beyond a doubt by the manner in which they have withstood the late exceptionally trying season, when plants apparently of a much hardier character have failed. I lately saw a bed of seedlings raised in heat in spring, and planted out in a very small state, that had made pretty plants, in a very exposed position where *Iresine*, *Coleus*, and similar plants, had almost or quite perished. In order to obtain, however, the full beauty of these lovely *Begonias* they should be reared to a good size under glass, and not planted out in ordinary years till the first or second week in June, when the beds are cleared of bulbs and

biennials: they will then look well at once, and have every chance of succeeding. Of course, when uniformity of colour is required, and plants of good named sorts are procurable in quantity, they will be the best, but for the majority of cultivators a packet of seed sown in very fine soil in February will answer every purpose. Prick them off into pots or boxes as they become strong enough to handle, and always look carefully after the smallest weakly growing plants, as in most cases they will prove the best.—J. GROOM, *Linton*.

Mimulus Semi-aquatic.—Excellent evidence of the fondness of *Mimulus* for moisture has this year been afforded by the luxuriant growth which they have made in the open air. Planted out in good soil, and heavily dressed with *Cocca* fibre refuse, they have thriven better than in any other previous season, thus showing how much they appreciate a cool temperature and plenty of moisture. A careful observance of the habit of the plant shows that it has almost the aptitude for branch rooting that characterises the *Watercress*, pushing out roots at every joint where these come into contact with soil or moisture. I find that they have a peculiar liking for *Cocca* fibre refuse, doubtless because this offers speedy root hold for the tender rootlets, and is also invariably damp and cool. In a similar way the *Musk* (*Mimulus moschatus*) likes plenty of moisture, and without doubt would make a good raft or semi-aquatic plant. Harrison's *Musk* under glass grows and flowers well where moisture is abundant; plants of it kept deficient of such moisture bear no comparison with those which have plenty of it. This is, without doubt, the most continuous blooming plant in existence, and I feel sure would, if kept in a fair temperature through the winter, bloom for ever. It is most useful for edging permanent plant beds with in conservatories, or indeed anywhere under glass where something is needed to give a gay appearance and give little trouble. Those who have marshy places or bogs within their grounds will do well to try all the more robust members of the *Mimulus* family in such a position, including the fine spotted varieties of Clapham's Strain, the finest and most robust of all the garden forms, growing well in the open air, and producing blooms from 2 in. to 3 in. across. Seed sown now in pans will produce plants large enough to prick off into small pots about Christmas, and these will make large plants consisting of some half-dozen shoots in the spring.—A. D.

Mimulus for Fountain Decoration.—Under the spray of the Boulder Falls in the Rocky Mountains, where indeed so much spray falls that one almost needs an umbrella, I gathered a small *Mimulus* native to that region, that was much more luxuriant than the same species gathered under other circumstances. There seems no doubt that the various species of *Monkey-flower* would make admirable subjects for fountain decoration.—*Gardener's Monthly*.

Campanula latifolia.—The remarks of "W. G." (p. 232) on the adaptability of this *Harebell* for naturalisation in wild places oblige me to point out that the plant is truly wild, and one of the greatest ornaments of our native flora hereabouts. It affects ditch-banks, water-courses, ponds, and river sides, and when seen in such places in masses it is charming. Though very beautiful the plant is, however, gross in habit, and like a *Doek* will grow anywhere, but seems most at home by brook sides. This may give a hint to those who may choose to plant it in such places. Like most of the family it passes through all shades from blue to white, and I have a mass of the white variety just now going out of flower.—THOS. WILLIAMS, *Ormskirk*.

The Spikenard of the Ancients.—Although Mr. A. Perry (p. 235) states what I am aware of regarding Sir W. Jones's "discovery," also Dr. Roxburgh and Dr. Royle, yet I have a set off in the opinion of Linnaeus, Pomet ("History of Drugs"), and Lewis ("History of the *Materia Medica*"), who also speak of the *Nardus indica* as a species of Grass, and carefully distinguish it from the *Nardus celtica*, which is a small species of *Valerian*, and from the *Nardus italica*, which is a *Lavender*. See also Sir Gilbert Blane's paper in the "*Philosophical Transactions*." Sir W. Jones in his paper argued as a philologist rather than as a botanist.—G. S. WINTLE, 10, *Paragon Grove, Surbiton*.

Martynia fragrans.—This fine Mexican annual is a most useful plant for conservatory decoration in autumn. In order to obtain good plants for this purpose the seed should be sown in a brisk heat, about the end of March or beginning of April, and the seed pan must be kept well moistened until germination takes place. Pot the young seedlings singly into small pots as soon as they are fit to handle, and grow them on in an intermediate temperature until the middle of June. After this time a cold frame will be found the most suitable quarter for them. Pinch out the points of the shoots occasionally, and give them increased root room as the season advances, always using a light rich fibrous soil, with plenty of drainage. Early in August give them a final shift into 9-in. or 10-in. pots, and in a week or so after moving them stop every shoot. By the middle of September they will have developed into fine sturdy plants, each

showing a dozen or more spikes of bloom, and for beauty of colouring, combined with a fragrance that will perfume a large house, this plant is not easily surpassed.—J. ROBERTS, *Gunnery Park*.

TREES, SHRUBS, AND WOODLANDS.

PLANTING FOREST TREES.

THE cold wet summer through which we have passed leaves the land in a state about the least fitted for planting operations, which should now be shortly commenced. Even where early cultivation was attempted, such as steam ploughing, trenching, and pitting, the land has settled down very little the better for the operations, and the warmth of soil which is found to be conducive to the success of early transplants will be lost to the young plants, many of which will not ripen their young shoots until the approach of winter. This places them in considerable danger from the spring frosts, and the Spanish Chestnut, in particular, often gets cut back by them upon wet land after such a season as the present. Upon very wet soils pitting is under any circumstances but a poor preparation for planting, as the water which draws freely to the holes keeps the roots cold and backward.

Many of the failures in planting are due to unsuitableness of soil and site, late removals, and the large size of the plants used. From the effects of wind-waving, which disturbs the old roots and ruptures the rootlets, arises the most fertile cause of the necessity for replanting or filling up. Careful observation shows that under ordinary circumstances of soil and planting, small trees planted out under 3 ft. high, will, even in moderately sheltered places, in a few years outstrip those put out at a height of from 5 ft. to 8 ft., and where the exposure is great the difference will be even more marked. Where the system of notching-in is adopted only small plants can be used, and to this may be attributed the great success which generally attends this method, which is much practised upon hilly districts, and where the lightness of the soil renders pitting inadvisable on account of the small amount of moisture which the land afterwards retains. Better results may generally be obtained by using *Firs* under 2½ ft. high, and deciduous trees under 5 ft., than by trees of a larger size. In making extensive plantations the following will be found useful ages at which to select trees:—*Larch*, two years seedlings once transplanted; *Silver Fir*, *Scotch*, and *Spruce*, two years seedlings which have had one year in fairly open lines; *Birch*, *Elm*, *Sycamore*, *Mountain Ash*, *Hornbeam*, and *Ash*, two years seedlings nursed either one or two years according to soil; *Oak*, *Beech*, *Horse* and *Spanish Chestnut*, planted out as seedlings, two years nursed, and tapped in the nursery; when both the soil and situation in which the plants are to be placed are good, an additional year in the nursery may prove of great advantage to them. Such as are tap-rooted, in particular, should have one year in tolerably good soil after being undercut. These instructions apply to trees intended for the woodlands only; such as are designed for parks, pleasure grounds, hedgerows, and screens, may be put out at any required size, and afterwards protected, watered, and mulched as the necessity for such treatment arises.

Great assistance in filling up *Oak* plantations may be obtained by dibbling in *Acorns* and by layering from suitable stools. The advantages of the latter method can hardly be realised by those who have never practised it upon a large scale. The support which the layers derive from the parent stool causes them rapidly to outstrip the growths from *Acorns* or from recent transplants. By selecting two years shoots and carefully layering them in cultivated ground, and at the end of the second year again layering the young plants, a considerable space around the original stool may be filled up in a few years; and one great advantage of the system is that there is no fear of wind-waving, even upon the greatest exposures, and the support which the new plants derive from the parent stool not only promotes rapid growth, but also enables it to be carried on upon sites where from poverty of soil trees cannot be planted with any prospect of success. Layers may either be cut away at the end of the second or third year, according to the quality of the soil; but when it is intended again to layer them from those first formed, no cutting away should take place until the process is finished.

The number of plants required per acre to plant up at any given distances may be calculated by dividing 43,560, the number of square feet in an acre of land, by the square of the given distance in feet; thus at 3 ft. apart 43,560 ft. divided by the square of 3, or 9, gives 4840; at 5 ft. apart, divide the same number by the square of 5, or 25, and the result is 1742. The *Scottish* acre containing 54,760 ft., and the *Irish* 70,560 ft., the same results may be obtained by treating these numbers in a similar manner. In filling up with *Acorns*, a system which may be followed with advantage in a season when these are plentiful, and when from the quantities lying upon the surface of

the ground the vermin are not so likely to attack those planted, these may be dibbled in in all open spaces as soon as they fall from the trees. By paring off the surface with the planting mattock, and afterwards stirring the soil with its opposite end, pointed like a pick, three or four Acorns may be dibbled into each selected spot at a depth of about 2 in., the ground being closed with the foot. The young plants will require to be kept clean for a year or two, when superfluous trees may be removed to the nursery, or used for filling up elsewhere. When planted in spring, choose the end of March or beginning of April; but the Acorns used should have been well kept.

Differences of opinion prevail respecting the advantages to be derived from Oaks raised direct from the Acorns in the woods, as compared with those which are transplanted from the nursery; but there is every reason to believe that as good timber can be obtained by the one method as by the other. Where the young plants are undercut in the nursery they generally flourish more vigorously after removal, and the process of heading down bark-bound and unhealthy-looking plants often, in a few years, gives them the lead of the uncut ones. Too much importance is attached to an undisturbed tap-root by those who forget that its main functions are lessened, or cease altogether, when the tree gets well established in the soil. Thus, when the top of an Oak assumes a rounded form the tap-root ceases to descend, even though the lateral roots may still continue active.

A. J. BURROWS.

AUTUMN BLUE BERRY.

(BILLIARDIERA LONGIFLORA.)

THIS is a delicate little wall shrub, perfectly hardy, having withstood the frosts of the late winter with no other protection than that

Autumn Blue Berry (*Billiardiera longiflora*).

afforded by a low greenhouse wall with a south-easterly aspect. Our sketch represents a tiny spray from a little plant about 2 ft. high, which is just now very pretty, the fruits being very large in proportion to the tenuity and stature of the plant, and of the most beautiful shade of lavender-purple colour. Ten or twelve seeds are contained within each fruit, the lining of the large inner cavity being of satin-like whiteness—indeed, an effective contrast with the glossy exterior. Apart from the reddish-crimson flowers and graceful habit of growth, this elegant little shrub well deserves a place amongst the more select of berry-bearing plants; the berries of this and several other species are, in fact, edible, but inferior in flavour to those of *Eugenia Ugni*. At a recent exhibition of the Royal Horticultural Society of Ireland Messrs. R. McClelland & Co., of Newry, had a small group of this species very prettily berried in $4\frac{1}{2}$ -in. pots, thus forming graceful and effective plants for indoor decorative purposes. I am afraid Mr. T. Smith had to answer many enquiries as to the name of the plant, for it was very often singled out from many more showy plants by ladies, who were, doubtless, as much attracted by the novel shades of colour afforded by its berries as by its slender and graceful habit of growth. It is Pittosporaceous and nearly related to the pretty but now-a-days sadly neglected old *Sollyas*

as will be seen, however, the shape of the fruit is very different. From "*Paxton's Botanical Dictionary*" we learn that the genus was named in honour of Julian Labillardière, a botanical traveller, and that it was introduced from Van Dieman's Land as long ago as 1810.

B.

INJUDICIOUS PLANTING.

IT often happens that in laying out a new place one is anxious to shut it in as soon as possible, and in order to effect this both trees and shrubs are often planted too thickly; but if such work were submitted to a practical man it would be so arranged that a long time would elapse before much thinning was required. Stevens's Green, Dublin, is now in process of improvement (?), and it is being done in this way: there are already numbers of half-grown trees on it, healthy and vigorous, and having a good forty-five or fifty years to run at least. They consist of Thorns, Elms, Laburnums, Ash, and others, and they are for the most part placed at sufficient distances apart to enable them to develop their proportions and produce the desired effects. But people cannot "let well alone;" other trees have been planted in the most reckless manner underneath, around, and amongst them; so close, in fact, that in many cases the branches of the established trees have already whipped the tops off the newly-planted ones. One could understand the reason of this proceeding if the space were ample and other and distinct trees were invariably put in to produce contrasts. But this is not the case; quite the contrary. For instance, in one place there is a fine group of six or seven thriving Elms whose branches already nearly touch each other; this space is crammed full of other Elms. In groups of Thorns which already touch each other, other Thorns are planted. In some few instances there has been a faint attempt to produce contrasts, and it is done in this way: In the case of a group of *Acer campestre*, *Platanus laciniata*, and a handsome Thorn, whose branches at present nearly touch each other, and which to a casual observer needs no "improvement," a number of other Thorns are planted all about and amongst them. In another group of Thorns a number of Sycamores have been planted so as to touch one another. In another group, composed of large Thorns, Elms, and a Birch, other Thorns have been planted underneath. In another place Sycamores are planted underneath Elms. In another, where a fine *Acer*, a Laburnum, and two Thorns touch each other, all round and underneath Chestnuts are planted; the tops of some of these have been already knocked off. In the case of new groups, trees 10 ft. or 12 ft. high are planted, so as to already nearly touch each other, and the ground underneath is thickly covered with shrubs; but a very short time will elapse before the life and death effort, portrayed by Mr. Baines (p. 218), will take place. It really seems incredible that in such a public place such things should be done, but there they are for all the world to see.

Newry.

T. SMITH.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Ruta graveolens variegata.—This deserves a place in all shrubbery borders; its variegation being so bright and constant makes it look in the distance as if it were loaded with white flowers.—T. SMITH, *Newry*.

Vitis Labrusca.—This handsome-leaved Vine is an excellent climbing plant, well worth a place on trees, stumps, or in half-wild places. It is very fine on the house at Belmont, Carlow, whence it was brought from Canada by Captain Thomas. Its delicate scent when in flower fills the woods in North America.—V.

Cut Leaved Alders at Wynnstay.—There are some fine spreading specimens of these at Wynnstay, which are very suggestive of the great value which what a botanist may call "a mere variety" may possess. A variety, at first noticed for a peculiarity in the leaf, forms a tree here about 70 ft. in the diameter of its spread of branches—a most picturesque object, and in all ways highly ornamental. There is a lightness in the foliage and spray of the tree which in contrast with the large wide spreading branches is peculiar. This is only one of several hardy trees in which a variety in the form of the leaf, in the angle which a branch bears to the stem, or some other peculiarity that appears small in itself, may be accompanied by a total change in the form or habit of the tree, or even in its size and the effect of its foliage in the landscape.—V.

The Exmouth Variety of Magnolia grandiflora.—With reference to the remarks of "J. C. B." (p. 240) as to the superiority of this variety, I may mention that any one not practically acquainted with the two kinds may easily distinguish them by looking at the under sides of the leaves, which in the ordinary form are green, but in the Exmouth or free-flowering sort are quite cinnamon-coloured. I have no doubt that intending planters may procure the true variety in any good nursery, and, although dearer than M.

gandiflora, it is well worth the extra outlay. As regards the time of planting most nurserymen keep a large stock in pots, and being full of roots they may safely be planted out at any time.—J. GROOM.

Weeping Birch.—A striking illustration of the habits of plants and trees to adapt themselves to particular circumstances is afforded by a Weeping Birch here, planted on a point close to the water's edge. Thus situated it is thriving in the most luxuriant manner, and its roots are really growing into the water in masses, and apparently quite at home.—T. SMITH, *Newry*.

Influence of the Scion on the Stock.—Whilst visiting the Amner nurseries, Edgware, lately, my attention was directed to some Laburnums that had been grafted last spring with the Golden variety; the scions had made a fair start, but the severe winter was too much for them; although it had not injured the stock it had completely killed the scions. This summer's growth of the stock, however, shows foliage tinged similar to that of the scion previously grafted on it. The shoots exhibiting this golden appearance start from below the scar left by the graft. At first sight I thought it was only weakness, but the vigorous growth of all the trees (seven or eight in number) showing this peculiarity was entirely opposed to this conclusion.—JOHN W. ODELL, *The Gardens, Barrow Point, Pinner*.

Cytisus villosus.—A large specimen of this (about 6 ft. high), quite unprotected, has survived the last winter safe and sound, and has produced a glorious mass of golden-yellow blossoms. A peculiarity belonging to this species is its habit of flowering in a small state; some seedlings here, not much more than a year old, are blooming as freely as old plants.—T. SMITH, *Newry*.

THE LIBRARY.

THE HEREFORDSHIRE POMONA.*—PART II.

THE second part of this, in all respects, valuable work on fruits is now before us. It contains beautifully-coloured figures and wood-cut outlines of forty-one different kinds of fruit. Amongst introductory papers are "Modern Apple Lore," and "A Sketch of the Life of Lord Scudamore," by Dr. Bull; also a paper "On the Cordon System of Growing Pears," by Sir Henry E. C. Scudamore Stanhope, Bart., with a representation of the Cordon Pear wall at Holme Lacy. This part also contains the following representations of fruit, viz.:

Blenheim Orange	Winter Pearmain	Black Foxwhelp
Gloria Mundi	The following Pears:	Dymock Red
Pott's Seedling	Williams's Bon Chrétien	Munn's Red
Tower of Glamis	Forelle or Front Pear	White Must
Winter Hawthornden	Louise Bonne of Jersey	Sam's Crab
Nelson Codlin	Beurré d'Amanlis	Sack Apple
Alexander	Flemish Beauty	Red Streak
Cox's Pomona	Beurré Harly	Cherry Norman
Cellini	Doyenné du Comice	Red Norman
Beauty of Kent	Pitnaston Duchess	White Norman
Herefordshire Pearmain	And the following Cider	Strawberry Norman
Scarlet Pearmain	Apples	Handsome Norman
Adams's Pearmain	Rejuvenated Foxwhelp	Black Norman
Lamb Abbey Pearmain	Best and Foxwhelp	Pym Square
Mannington's Pearmain	Red Foxwhelp	

The following extract will give an idea of the way in which the matter relating to the fruits figured is arranged:

"1.—WILLIAMS'S BON CHRÉTIEN.

[Syn.: *Wheeler's; Bartlett; D: Livault; Williams's.*]

"In Amitermis vale, the Sabine boars
Added Bon-crétiens to their former stores."

(*Rapin, "The Orchard," translated by Gräbner.*)

"This highly-esteemed Pear was raised a short time previous to 1770, by a person of the name of Wheeler, a schoolmaster at Aldermaston, in Berkshire; from him it was obtained by Mr. Williams, the nurseryman at Turnham Green, Middlesex, and being by him first distributed, it received the name it now bears. In 1799 it was introduced to America by Mr. Enoch Bartlett, of Dorchester, near Boston, through whom it became generally distributed, and has ever since been known there by the name of the Bartlett Pear. It attains the highest perfection in America, and is esteemed as the finest and best keeping Pear of its season. It has even been brought back to England with its new name.

Description.—Fruit, large, obtuse-pyriform, irregular, and bossed in its outline. Skin, smooth, at first pale green, changing as it ripens to clear yellow, and tinged with streaks of red next the sun. Eye, open, set in a very shallow depression, but more generally even with the surface. Stalk, an inch long, stout and fleshy, and inserted in a shallow cavity. Flesh, white, fine-grained, tender, buttery, and melting, with a rich, sweet, and delicious flavour and powerful musky aroma.

"An excellent autumn dessert Pear; in season in August and September. The tree is healthy and vigorous, but not a regular and abundant bearer. It succeeds best as a pyramid or standard on the Pear and Quince Stock, when the fruit is much better flavoured, though not so large as when grown on a wall. The fruit should be gathered before it is ripe, at intervals of a few days, that they may not all ripen together—for when ripe, it soon becomes mealy and decays. Its cultivation by the London market gardeners has become more limited than it was, in consequence of its fickleness in bearing.

"An excellent coloured representation is given of this Pear in the 'Transactions of the Royal Horticultural Society' (London), Vol. II., p. 250, where, and in Vol. III., p. 357, its history and description are given." H.

EUROPEAN FERNS.

MESSRS. CASSELL, PETER, & GALPIN have just issued the first part of this new addition to our works on Ferns. The design of the publisher is to supply a complete account of all the indigenous Ferns of Europe, including their local distribution, and directions for their culture. In the introduction the author gives a brief survey of Ferns in general, showing their connection with the flower forms of vegetable life, and their position in the vegetable kingdom. Then follows a description of the various organs of Ferns, a part of the work which is treated with much clearness, so much so that with such aid even the moderately informed may be able to distinguish a Fern from all other plants of similar appearance. Accompanying this first part is a coloured plate giving a tolerably good representation of the Ostrich Fern, which according to our author is the largest and handsomest of the Ferns of Europe. This is only partly true. It may fairly claim to be the handsomest, but it is not the largest, if we take into comparison the Royal Fern and the common Brake. The characters are written in a pleasing popular style, and deal with both the superficial aspects of the plant and its anatomical structure. The following extract will give the reader some idea of the plan adopted by the author:—

"**Onoclea Struthiopteris**, Hoffm.—This is the largest and handsomest of the Ferns of Europe, and, indeed, has some pretensions to be considered a tree Fern. This results from the caudex forming an upright thick trunk, which, however, never attains to any height, reaching at most to three-quarters of a foot: still, in nature and construction it is precisely like the large stems of the tree Ferns of tropical and sub-tropical countries. From beneath the surface of the ground the caudex gives off stolons, which run for 7 ft. or 8 ft., and propagate the plant. The fronds are of two kinds—barren and fertile, the latter bearing the sori. The barren fronds are very numerous, and form a magnificent vase-shaped crown of foliage of very regular arrangement. They are of large size, sometimes attaining a length of as much as 5 ft., though usually about 3 ft., and are elegantly curved outwards. The petiole is short, and is dilated at the base, where it joins the stem, and there covered with nearly black scales, which are not torn or lacerated; on section, the petiole presents two oblong curved vascular bundles. The general form of the frond is broadly oblong, gradually diminishing in width at the base, and abruptly narrowed at the apex; it is divided into very numerous pinnae. These are all sessile; the lower ones are small and distant, usually turned downwards, and at the very base of the petiole become brown and scale-like; the main pinnae are 4 in. or 5 in. long, narrow, slightly curved towards the apex of the frond, and tapering to the point; they are very numerous, and vary considerably in proximity to one another, being usually just in contact but not unfrequently so closely placed that they overlap. Each pinna is simply cut into numerous, simple, oblong, blunt segments, which are not again divided or toothed. The general appearance of the whole frond is not unlike that of the common Male Fern, but it is a paler and brighter green. The venation of the segments of the pinna is remarkable in being quite simple, not forked or reticulated."

No mention is made of the deciduous character of the plant, a point of much importance from a cultural point of view. The notes regarding the plant's history, the derivation of the name, and the remarks on culture, will give additional interest to the work.

C. M.

Burnham Beeches,* "remnants of the sylvan past," and lately bought by the Corporation of London for the people, have been made the subject of a small volume by Mr. F. G. Heath. Woodcuts illustrating the spring, summer, autumn, and winter aspects of the Beeches are given, and the letterpress is full of interesting facts concerning them and Stoke Poges Church and graveyard, the last the resting place of the poet Gray.

* London: David Bogus. Hereford: Jakeman & Carver.

* "Burnham Beeches." London: Sampson Low, Marston, Searle, and Rivington.

NOTES OF THE WEEK.

New Pontederia.—The beautiful new aquatic in the Royal Botanic Society's Garden in Regent's Park, to which we made allusion some time ago, still continues to flower and grow so rapidly that it now covers half of the Victoria Regia tank. The flowers are also very freely produced, as many as fifty spikes having already appeared. The blossoms, though they possess exquisite beauty, unfortunately last in perfection but a day, a circumstance which somewhat detracts from its merits. It agrees with a specimen in the Kew Herbarium, the name of which has not yet been published.

The True Linden's Tillandsia (*T. Lindeni vera*).—There is now in flower at the Victoria and Paradise Nurseries, Holloway, the true and very scarce *T. Lindeni*, which is a superb plant for stove decoration. It is, in point of beauty, much superior to the kind generally grown under that name, and of which a coloured illustration was given at p. 466, Vol. X. of THE GARDEN. The foliage and habit of growth, however, are so similar that they are not easily distinguished when not in flower, as both have the leaves arranged in a tufted rosette-like manner and each leaf is conspicuously ribbed, deeply channelled, and has a gracefully curved habit. The flower stems of the true *T. Lindeni* are somewhat shorter and the flattened inflorescence is considerably broader. The membranous closely appressed bracts are of a rosy pink colour and form an almost oval expansion 4 in. long, whereas in the commoner kind the flattened portion is longer, narrower, the scales larger, more loosely arranged, and of a greenish hue. The flowers of both kinds are borne in much the same manner, and are nearly identical in colour, the true one perhaps being a shade or so darker in tint. Two such distinct plants certainly ought to receive separate specific names, though *T. Lindeni* is said to be a very variable plant. Mr. Williams's plant was deservedly awarded a first-class certificate at South Kensington on Tuesday last.

Zygopetalum Wendlandi.—This rare Orchid is now in flower in Messrs. Veitch's collection. Though not so showy as many of the terrestrial kinds it is a desirable sort to have in a collection on account of the delicious perfume emitted by the flowers, which are of a pale olive green, with a rather broad lip of a pale purple, bordered with white, and much crisped at the margin. It is a native of Costa Rica.

Lapageria rosea superba.—A fine plant of this beautiful variety planted against the back wall of an unheated frame is now an object of much attraction in Mr. Parker's nursery at Tooting. It has been doubted whether there exist any distinct varieties of this plant in cultivation, it being thought that any variation in the size or colour of the flower from those of the type is entirely due to culture. Whether this is so or not it is difficult to ascertain, but the example in question is decidedly superior in point of size and richness of colour to those of the ordinary form. Its superior beauty may certainly in this instance be owing to good culture, combined with a cool, moist, and somewhat shaded position, and it admirably exemplifies how the plant may be grown in an ordinary frame without the aid of artificial heat.

Dahlias at Swanley.—Mr. Cannell has now in flower in his nursery, besides a large collection of Dahlias of the ordinary florists' type, some remarkable kinds, which from their pure and simple beauty win numerous admirers. These are the original types from which have sprung the hosts of garden varieties. They include such species as *D. Cervantesi* and *D. coccinea*, with brilliant orange-scarlet flowers and yellow centres; *D. lutea* and *Paragon*, probably forms of *D. variabilis*, the former with pure yellow ray florets, the latter with the outer florets of a rich Plum colour, edged with red, as well as a yellow centre; *D. glabrata*, a dwarf and trailing kind with rather small flowers, but of a pleasing soft mauve tint. *D. Yuaiezi*, however, is the most interesting of all, as it shows an intermediate stage, as it were, between the original types and the perfect florist's flower. It has been aptly named the Cactus-flowering Dahlia, for there is nothing which it so much resembles as some of the common kinds of *Cereus*, except it be those of the Carolina Allspice Tree (*Calycanthus floridus*), as all the central florets are transformed into the strap-shaped kind, and are arranged not at all symmetrically. The colour is brilliant deep scarlet, which contrasts charmingly with the deep green foliage. The green-flowered kind, *D. viridiflora*, is a singular monstrosity not often met with. It is interesting, as it illustrates well the intimate connection between foliar and floral organs.—W. G.

Williams's Kidney Bean.—In an extensive trial of French Beans in the remarkably well-managed kitchen gardens at Penrhyn Castle, Mr. Speed found this to be the earliest and the hardiest. The fact is worth noting in connection with a vegetable where hardness and earliness are so great a gain.—V.

Yuccas in the Carse of Gowrie.—In the gardens of Sir P. M. Thriepland, Bart., Fingask Castle, Carse of Gowrie, Perthshire, thirteen plants of *Yucca gloriosa* are now in flower, the flower spikes ranging from 7 ft. to 10 ft. in height. *Yucca filamentosa* and *flaccida* are also in flower in the same garden; one plant of the former bears five spikes of blossom, and the whole presents a very fine appearance.—BETA.

Aspen Leaves in Autumn.—I never anywhere saw trees more beautiful in colour than some groups of the Aspen by a roadside in Ireland in the middle of September (16th), the stems of the trees being clothed with small-leaved Ivy, and the leaves a fine deep claret red. The distant effect was very brilliant. It is not only American trees that are remarkable for their colour in autumn.—V.

Statice tatarica atro-sanguinea.—Most of the hardy kinds of Sea Lavenders are very desirable rockery or border flowers, and this is one of the best, as it is dwarf in habit and produces a profusion of its repeatedly-forked panicles, on which are arranged small red flowers surrounded by a cup-like, dry, membranous calyx, which, being white, forms a good contrast with the red flowers. The variety *atro-sanguinea* differs from the original in its flowers being of a deep blood red. It now forms a conspicuous ornament on the rockery in Mr. Stevens's garden at Byfleet.

Loasa volcanica.—This pretty species is now an object of much beauty in Mr. Joad's garden at Wimbledon, where it is growing in a cool airy house devoted entirely to similar half-hardy subjects, and where it flourishes with unusual vigour, having stems from 3 ft. to 4 ft. high, and producing its pretty white blossoms in profusion. The singular markings of the flower of this plant were illustrated by an engraving in THE GARDEN last year (p. 281, Vol. XIV.). *L. lateritia* is another handsome kind with curiously-shaped flowers of a brick-red colour. Mr. Joad has it growing against an outside wall.

Gladiolus Saundersi.—In several hardy plant collections this beautiful South African *Gladiolus* forms a most attractive feature, but it does not appear to be generally grown, though it is perfectly hardy and of very easy culture, only requiring to be planted in a sunny position in a light rich soil. *G. purpureo-auratus* is another very desirable species, though not so showy as the last, the flowers being of a creamy-white heavily blotched with vinous purple on the lower divisions. It is also a native of the Cape.

Ceanothus Arnoldi.—This is one of the finest of showy North American shrubs, and it is rendered all the more desirable by its flowering during the autumn, when the beauty of the other kinds is for the most part over. It bears long loose clusters of deep blue flowers, which last for a considerable time in perfection in a cut state, and it is therefore well adapted for cutting, and the list of blue flowered plants adapted for such purposes at this season is by no means long. It is quite hardy when planted against a wall in the Misses Christy's garden at Coombe Bank, Kingston Hill.

Lisianthus Russellianus.—In Mr. Joad's garden at Wimbledon we met with this old-fashioned plant the other day in flower. The singular beauty of its large cup-shaped blossoms at once suggests the question—Why is it not more generally grown? Its being reputedly difficult to manage is probably the reason, but it certainly well repays any amount of care that may be bestowed upon it. This and other beautiful Gentianworts were years ago amongst the most esteemed of garden favourites, and even now few plants can surpass them in point of beauty.

Pratia angulata.—This elegant trailing New Zealand plant forms a pretty object just now in Messrs. Veitch's nursery at Coombe Wood, where it is allowed to trail over half-buried stones. Masses of it growing in this way are studded with white flowers similar to those of the ordinary white bedding *Lobelias*, and later in the season these will be succeeded by purple fleshy fruits, each about the size of large peas, rendering the plant an object of attraction for many weeks together. It is perfectly hardy and is a capital plant for rockwork. It is by no means new, though it may be better known by its synonyms *Lobelia littoralis*, *L. ilicifolia*, or *Pratia littoralis*.

Limnorcharis Humboldti.—This pretty aquatic plant, which is seldom seen outside of a stove or greenhouse, succeeds admirably in the open air during summer at Tottenham, where it is now finely in flower. Its delicate pale yellow saucer-shaped blossoms have a very pretty appearance floating on the surface of the water mixed with its own and other foliage. It also grows and flowers profusely out of doors in a heated pond in Mr. Beaufoy's garden in Lambeth.

Late Gooseberries.—Good late Gooseberries are as welcome to many as Grapes, and I noticed lately in Penrhyn Castle Gardens a simple and excellent way of keeping them, which may be worth recording. A square of Warrington is covered with common netting

just a little higher than the head, so that one may walk about inside with ease: the netting is supported on rough uprights and laths across the whole very simply made. Where the net usually touches the ground—the weak place the birds so soon find out—is made quite safe in this case by a strip of close wire netting about 18 in. high ran all round. Not a bird can get in. This is a better and much simpler plan than that of the border and wall covered with wire netting sometimes seen.

Gunnera manicata and G. scabra.—The fruiting spikes and leaves of these noble plants shown by Mr. Green at South Kensington on Tuesday last, from Sir G. Macleay's garden at Pendell Court, conclusively established their distinctive characters beyond doubt even to those who have hitherto considered the two species synonymous. The much longer spikes and small flexible spikelets, combined with the decidedly reniform leaf, of *G. manicata* are entirely distinct from the much shorter spike and short, stiff spikelets of *G. scabra*, the better known kind. On account of the large size of its foliage the former is the more ornamental of the two, though *G. scabra* makes fine specimens, as may be seen by the superb example at Kew.

Seedling Begonias.—Amongst new unnamed varieties of *Begonia* now flowering in Mr. Cannell's nursery at Swanley, is a seedling from B. Pearcei, to which in manner of growth it bears a strong resemblance. It is, however, in all respects infinitely superior to that kind, the foliage attaining more noble proportions, being at the same time more richly and distinctly marked. The flowers are large, much larger than those of B. Pearcei, and of a rich orange yellow, contrasting finely with the deep rich hue of the foliage. It is altogether a striking novelty, and one that will undoubtedly be welcomed by the horticultural public. As seen growing at Swanley it gives to all other kinds an admirable and most effective contrast.—J. C.

Hail Storm Relief Fund.—The amount received or promised up to September 5th in aid of those who sustained losses by the hail storm which occurred on the morning of August 3rd is £498 13s. 10d.

The Manetti Rose amongst Evergreens.—Allusion has already been made in THE GARDEN to the desirability of relieving masses of evergreen shrubs of their monotony by planting amongst them flowering plants chosen for their suitability for the purpose. One of the very best subjects for naturalising amongst low-growing shrubs would be the Manetti Rose. Its vigorous, robust nature enables it to grow strongly amongst evergreens; indeed, it really appears to be quite at home in such situations. The flowers, though not large, are produced in great profusion, and are of a pleasing colour, forming a charming relief to the deep green foliage of the *Rhododendron* and *Laurel*. The idea of planting this Rose amongst evergreen shrubs has been suggested to me by seeing a large bush thus situated in Mr. Stevens's garden at Byleet, and the effect was so good that I consider it worth recording. Most of your readers will have observed the charming effect produced by the common *Brier* in the lanes and hedgerows when surmounting the surrounding vegetation; it crowns it with irregular festoons and masses of bloom. Some such effect might be easily produced in our shrubberies, in the wild garden, or even amongst the clumps of evergreens which are to be found in the near vicinity of the dwelling, and which often sadly need that something should be introduced amongst them to relieve them of their sameness and formality.—JOHN CORNHILL.

Alternantheras.—Where carpet gardening is carried on, the bright colouring of *Alternantheras* is indispensable, but the past season has been most disastrous to them. As a rule, instead of filling up the small space allotted to them, they have dwindled away, and lack the brilliant colouring for which, when in a flourishing condition, they are prized. The only resource left is to lift them at once, and plant them in shallow boxes for providing cuttings next spring. They should be set in a frame or cool house at first, and when established removed to shelves near the glass, where a growing temperature is maintained, and if planted a little deeper in the soil, when lifted they will be found furnished with roots on each stem, and may be divided in spring, so as to form a large supply with a minimum of labour as regards propagation, as the smallest rooted pieces make excellent plants in a very short period.—J. GROOM.

Ptelea trifoliata aurea.—Anything that in this rainy, sunless season gives brightness and life to ornamental grounds should be brought prominently into notice. Trees of this are here in the highest degree ornamental, being so beautifully golden as to be conspicuous even from long distances off. The foliage is ample and the growth free, properties which planters should not overlook.—T. SMITH, *Newry*.

THE INDOOR GARDEN.

PITCHER PLANTS (NEPENTHES).

WHEN first the handsomely marked Bornean species of these singular plants became sufficiently plentiful to be procurable, many people who had the convenience of a stove attempted their cultivation, but in more cases than otherwise with indifferent success, no doubt through comparatively little being known of the course of treatment which they require. A knowledge of the temperature and humidity of the atmosphere from whence they came was enough to point conclusively to the fact that without the means of, at all times in the year, being able to accommodate them with as much heat as most hot-region plants require, it is of little use attempting to grow them, as though they may be kept alive with less than this, they will never acquire the strength necessary to produce their curious pitcher-like leaves in the manner required, and without this there is little interest attached to them. Another and frequent reason through which the plants failed to form pitchers more than very sparingly, even when they grew in other ways freely, was either too much shading, or what amounts to much the same thing, being too far from the glass. For with only one exception, and that *N. lanata*, amongst all I have grown, I have found that if their heads are kept within a few inches of the glass they succeed best, having a strength and vigour in both root and top growth not attainable by any other means; and, as might naturally be supposed, they acquire a higher degree of colour when kept up close to the roof. Another matter of more importance with these plants than any others in cultivation, is never to injure the roots in potting, for if this should occur to an extent that would scarcely have any perceptible effect upon most things, it will in all probability cause their death, or bring about a condition little better than actual loss. I may here remark for the benefit of those who have not had any experience at all with them, that their roots are so fragile and dead looking, even when the plants are in every way healthy, that I have known them all pulled off under the impression that they were dead. They are very spare rooters, needing much less room than most things, and when repotting becomes requisite, there must be no attempt at shaking any of the old soil away. Consequently from the first it is necessary that the material should be such as is least likely to get into a decomposed state, for when it is close and soapy the roots cannot live in it, and from the large amount of water they always want it is liable to become sour, as when in active growth they need watering freely every day, and during the winter must be kept much more moist than the generality of plants. It will take, even under the most successful course of treatment, four or five years from the time of a young plant being first well rooted to its arriving at a size that will exhibit the full development of which it is capable; for, not until it has been twice headed back, and has again got furnished with from four to six shoots, each bearing their full complement of pitchers, has all that is desirable been attained; consequently it will be easily understood that the best and most lasting material that it is possible to find wherein to grow the plants will get so completely decomposed through the necessity of its being kept all but saturated with water, that it becomes like soft putty, in which condition the roots cannot exist; and, as already stated, they are so brittle that the old material cannot be got away in the ordinary manner, but can be effected by means of a painful of tepid water in which to plunge the ball with both hands under it, carefully moving the fingers so as to remove the exhausted matter. With a little time and patience in this way the roots can be wholly preserved in a perfectly clean state ready for transferring to a fresh pot with new soil; but on no account should there be any attempt at opening them out, as this will most likely end in their being much injured. The best kinds, such as *N. sanguinea*, *N. Rafflesiana*, and *N. lanata*, are more tender-rooted than the commoner species. About the end of February or March is the most suitable time in the year for either shifting on into larger pots those young and medium-sized plants that want more root-room; or for washing out, as above described, any older examples that need all new material. Pots proportionately so large as would be required for the generality of plants would not do for *Nepenthes*, as if too great a body of soil is present it directly gets sour. The largest specimens I ever had were grown in pots not more than 10 in. or 12 in. in diameter. The manner these plants are often allowed to run up straggling to a considerable height on a rafter or pillar is not the way for seeing them to the most advantage, as when the shoots of the best sorts have attained 4 ft. or 5 ft. in height, with some much less than this, the pitchers assume a character which is understood amongst growers as run-out; that is, they come devoid of their wing-like appendages and are very different in form from those which are produced by the leaves on the stems before they get such a height. The best position for them is hung up to the ridge of a span-roofed house standing ends north and south with their shoots

within 1 ft. or so of the glass, lowering the pots as the tops advance with a thin shade when the sun comes on them, but none at other times. If suspended alike up to the roof in a hip-roofed or lean-to structure facing south they will require a thicker shade in bright weather, but this will be easily seen, as if they get too much sun the leaves will assume a deep crimson colour instead of being green tinged or mottled with red, which latter is an evidence of the robust health essential to the full development of the pitchers that should be produced at the extremity of every leaf. When all the cultural conditions requisite for their well-being are present, even the leaves of *N. Rafflesiana*, and others of like habit, that are made slowly through the autumn and winter will, in the spring, when more heat is present, open the small pitchers formed during the dull season. I have been particular in describing somewhat in detail the appearance and necessary condition of the roots of the plants, as also the position in the house they require to be grown in, as well as their disposition to pitcher freely, for the presence of these in a large and highly coloured state is the certain test of the plants having all they want; in this condition, thus suspended where an opportunity

Nepenthes Rafflesiana as a basket plant.

exists of exhibiting to the full their most singular beauty and graceful habit, I think it will be admitted that there are none in the whole range of cultivated plants more generally interesting or more deserving of a place. For the help of those who feel inclined to grow them a few hints as to the temperature, air, and moisture requisite may be of use. The conditions necessary to grow Cucumbers well in the winter, viz., heat, humidity in the atmosphere, and very little direct admission of air, will be found such as to well suit *Nepenthes*; at the same time they will bear as much heat as any plants in existence. The air of the house must never be allowed to get dry, and for some twelve weeks in winter they will need no shade nor any air more than reaches them through the laps of the glass and other similar places of ingress. They should at this season be watered at the root every other day, with a syringing overhead through the spring and summer; water at the root and syringe every day, keeping them as warm day and night as the means at command will permit of, but not cooler than Cucumbers want to support free growth and continuous bearing, with less external air admitted directly upon them in the summer than Cucumbers will do with, and shade as already spoken of. A warm, moisture-laden atmosphere must always be present, and plenty of tepid

water to the roots is indispensable to their healthy existence. This obviously renders an abundance of drainage in the pots necessary. So far as insects go, the continuous use of the syringe keeps down all but brown scale, which, if it happens to get upon them, must be got rid of by sponging with clean water. They are too soft in texture for the use of any insecticide to be safe. The best kinds are—

N. Rafflesiana.—Large, handsome pitchers, flask shaped and deeply spotted with dark brown; wings prominent and crested; the lid broad and ample. This, for its fine effect and general good qualities, has not yet been equalled. I have had it with pitchers that held over a pint fairly measured.

N. Hookeri.—Nearly allied to the above. A compact-growing, smaller-pitchered species, similarly marked.

N. sanguinea.—A very stout-growing, long and large-pitchered species, with intense sanguine colour in the upper portion of the pitchers; the wings are narrow; the lid erect and small. Very scarce and high-priced, and likely to remain so.

N. lanata.—Another very stout-growing species of a remarkably pale yellowish-green shade; the pitchers, tinged with red, are large, long, and prominently furnished with hair-like appendages. This kind I have found does better hung a little further from the glass and shaded a little thicker than some of the others. In rarity and price it is similar to the last named.

N. ampullacea picta.—A stout, small-growing species, with prettily spotted pitchers, produced not only singly from the extremities of the leaves, but in clusters from the stem.

N. Sedeni.—A very pretty small-growing hybrid, with long pitchers, dilated at the base and thickly spotted with red.

N. hybrida maculata.—Another smallish grower, with longish cylindrical, deeply streaked or spotted pitchers with ciliated wings. There is one peculiarity in both this and the last mentioned kind; that is in the pitchers coming almost wholly green and devoid of colour when the shoots attain above a certain height.

N. Dominicana.—Another fine, free-growing hybrid, raised like so many others at Messrs. Veitch's, with good-sized, handsome, highly-marked pitchers.

N. Courti.—Also a hybrid of Messrs. Veitch's, a very distinct and handsome dwarf variety, having large, deeply-crimson, spotted, flask-shaped pitchers.

N. distillatoria.—A well-known, stout-growing kind, that produces its long green pitchers freely. There are several other species; but whether in a living state in Europe, I am not certain. Amongst them is the Rajah, an immense kind, represented to bear pitchers as large again as any yet in cultivation. When this makes its appearance no doubt it will produce a sensation.

It is a healthy sign of improved taste in horticulture to see beauty and singularity of form being appreciated as much as colour alone. That this is so, is evident from the increased sale for such plants as *Nepenthes*, the cultivators of which through the kingdom at one time might be counted on the fingers; but now those who grow them for sale have to propagate them by thousands to supply the demand.

The accompanying illustration represents a vigorous young plant of *N. Rafflesiana*, such as under good cultivation may be had at the end of the first year's growth, beginning with an ordinary "trade" sized plant.

T. BAINES.

PROPAGATION OF LAPAGERIAS.

MR. BAINES'S remarks on this subject (p. 248) simply amount to this, that never having himself grown or seen *Lapagerias* of the size and age described by me, as he confesses, he concludes that they cannot be produced; therefore, anything anybody may assert to the contrary must be wrong. Horticulture is not however bounded by the experience of any single individual, and assuredly not so in the present case, as I am able to prove. The plants which I described I saw and took note of on the spot, and I had before seen them on several occasions, from the time when they were layered till I wrote about them. The plants referred to by me as being layered last autumn twelvemonth I am personally sure about, but when in the nursery I asked if they were the previous year's plants, simply to make sure, as they had been moved out of the propagating house since I had seen them before to make room for this year's stock. But this is not all. I have a plant of white *Lapageria* in the gardens here which I procured from Handsworth last autumn as soon as it was lifted out of the propagating bed, where it was layered in the autumn of 1877, or less than two years ago. This plant I have had uncoiled to-day and counted the shoots, of which there are twelve, exclusive of a strong sucker pushing above the soil and a number of "leads" some inches in length. The longest of these shoots is about 11 ft. in length, other three are not much less, and a few only are under 2 ft. Six of the above number proceed direct from the stool

at the bottom, one about 2 in. above that, and the remainder from breaks higher up. This plant was not in existence in 1877, and this I assert on my own knowledge and responsibility, and the same can be amply verified if needful. I have been particular in stating the number of shoots, &c., as in a former communication Mr. Baines speaks of annual shoots, a term which I do not altogether comprehend. In a *Lapageria*, as in a Peach or a Vine, &c., I call a shoot a "shoot" whether it proceeds from the root or from a break on another branch, and I expect the general reader apprehends me in this sense. All help to extend the plant, and the subject under discussion is the getting up of *Lapagerias* quickly. Any method which accomplishes that is, I take it for granted, the best. I hope that Mr. Baines is therefore under no doubts now about my meaning. I can add no more. So far as I am aware Mr. Baines himself is the only one who still continues to treat *Lapagerias* upon the old method of propagating them from cuttings and eyes. J. S. W.

PLATE CXCVIII.

COLUMBINES.

THE *Aquilegias* constitute a very interesting and beautiful genus of hardy herbaceous plants. They are easily cultivated and their graceful foliage and handsome flowers amply repay any attention that may be bestowed on them. *Aquilegia vulgaris*, the best known species, or some of its many varieties, is that universally cultivated in cottage gardens. There are single and double forms of it in many colours, but most frequently they are purple, reddish-purple, and rose coloured. The pure white variety of it, with large flowers and elegant pale green glaucous foliage, is the best. Columbines are very easily raised from seeds, and any particular variety may be increased by dividing the roots. They all succeed perfectly in any ordinary garden soil.

The annexed plate represents two North American species, viz., *A. cœrulea* and *A. chrysantha*, and the hybrid variety *A. cœrulea hybrida*, obtained by crossing the two sorts just named. The result of the cross has been the production of a very beautiful variety of a much more robust habit than that of *A. cœrulea*, with sepals of a delicate pale blue and petals yellow or primrose coloured. All of the above are hardy, but they do not succeed so well in open borders as they do in pots. Large numbers of them are grown at Loxford Hall for the decoration of the greenhouse and conservatory during the summer months; for culture in pots they are usually raised from seeds, and in order that good flowering plants may be obtained the following season the seeds should be sown in April, and as soon as the young plants are large enough to handle they should be pricked out, about a dozen together, in a 5-in. or 6-in. pot. When these have made some growth let them be potted off singly into small pots, repotting as the plants require it. It is not desirable to use large pots; indeed, I find that Columbines do not succeed so well in large pots as in those of moderate size; a 5-in. pot is quite large enough for *A. cœrulea*, while strong plants of *A. chrysantha* and *A. cœrulea hybrida* succeed best in 6-in. or 7-in. pots. While making their growth they may be kept in a cold frame or they may be placed out of doors in an open position. If they are in frames the glass lights must be removed whenever it is possible to do so.

The insect pests that chiefly attack the *Aquilegia* are red spider and green fly, but neither of these does much injury, and indeed they seldom appear at all if the plants receive no check, and are syringed daily with clean rain-water. Our plants are wintered in cold frames, and during the dull months they do not receive much water, merely enough to keep the soil moist. Allowing them to become rather dry and then giving them a good soaking of water is better than giving dribbles and often. I permit the plants to remain in the frame until the first flowers open, when they are transferred to the greenhouse. The rising flower-stems come in contact with the glass, and when that happens it is necessary to raise the lights a little.

The soil best adapted for them is rather clayey loam, to which should be added a fourth part of leaf-mould and nearly as much rotten manure and some sand. All the species and varieties of *Aquilegia* with which I am acquainted succeed under this treatment.

A. glandulosa is a very handsome species, but I cannot say that it has done well with us here. Plants of it make but little growth, and consequently they are frequently attacked by insects. This species succeeds well north of Aberdeen; probably the south of England is too dry and hot for it, as it has been introduced from the mountainous districts of Central Siberia. *A. alpina* is rather like it in its manner of growth under cultivation; it is also from a high mountainous district in Central Europe. The plant is dwarf and the flowers very pretty.

A. Skinneri is a very distinct species that should be grown in a select collection. It succeeds better in the open border than any other with which I am acquainted, except the common garden Columbine (*A. vulgaris*). It is almost as robust as *A. chrysantha* when grown in pots. I had a plant of this species in a 7-in. or 8-in. pot with nearly 100 flowers on it. The sepals are orange-scarlet, and the petals yellow. It flowers the earliest of all that I have named. *A. californica* resembles the last in colour; the flowers are, however, not quite so large, and the plant is taller and of a more straggling habit.

A. pyrenaica is another free-growing handsome species with purple sepals and bluish-purple petals. Its flowers are drooping and produced very freely.

Whether for the herbaceous border or for pot culture all the above may be freely recommended. Cut flowers of them are also very beautiful in vases. J. DOUGLAS.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Tuberous Begonias as Basket Plants.—We find these *Begonias* to answer admirably when grown in hanging baskets; in fact, with us they both grow and bloom much more freely than when grown in pots. This is doubtless caused by the roots not being so much confined as in pots. The way in which we use them is as centre plants in the basket, employing some other plant to cover the outer surface. One basket planted in that way with a seedling variety very much like *Vesuvius* has seventy flowers now open, and the outer surface is covered with a dense mass of Harrison's Musk, which is also in full bloom. The pale yellow flowers of the Musk, and the scarlet blossoms of the *Begonia* produce a striking effect. We find it necessary to use baskets of a considerable size; ours are of a semi-circular shape, made of thin wire, and are about 11 in. in diameter at the top, and 10 in. in depth at the centre. The compost which we use is a mixture of equal parts loam, leaf soil, and fibrous peat.—H. J. C.

Draining Pots.—Judging from the elaborate directions for this operation which are usually given in *extenso* every time that the culture of pot plants is alluded to, one is led to think that some difficulty is found in doing it so as to completely guard against stoppage more or less complete. I am tempted, therefore, to submit for the consideration of more experienced gardeners than myself a plan which I have never once found to fail during the last three years, and which, moreover, is very expeditious and easy. It is to put one crock over the hole and then an inch more or less of Cocoa-nut fibre refuse. You can no more choke this than you could a sponge.—C. H. G.

Disa grandiflora.—Ireland would seem to be pre-eminently the country suitable for the culture of this superbly beautiful terrestrial Orchid. I well remember the examples of good culture grown by Mr. E. Culley, the gardener at Ferniehurst, and Sir William Marriot had in his garden at Down House, Blandford, numerous three-flowered stems, the individual flowers on which I never yet have seen surpassed in size and vivid colouring. An eight-flowered spike of the *superba* variety is well represented in Warner's "Select Orchids," but it is very rare to see all the blossoms on these many-flowered spikes in the same fresh and perfect condition as is there shown. I think Mr. F. W. Moore may fairly throw down the gauntlet to English growers with his nine-flowered spike. A week or two ago a private grower, near Purdysburn, Belfast, advertised two specimen plants for sale "one having twenty-one flower-spikes, the other sixteen flower-spikes, with from five to eight flowers on a spike, clean and healthy plants." In a London nursery I recently saw a large pan of this plant bearing over twenty spikes, but I am afraid that but few of these would produce five, let alone eight flowers. I saw the Glasnevin plants this season, and very fresh and healthy they were, with their great stout spikes leaning towards the sun in a way which recalled to mind the late Dr. Harvey's description of how this plant on Table Mountain grows beside a stream, its leaves being overshadowed by the foliage of *Restias*, but the flower-spikes shoot up through the screen and bathe in the sunshine above. One of the most distinct in colour of all *Disas* is *D. Barrelli*, an orange-scarlet form introduced by Mr. Bull a few years ago. If many-flowered spikes are desired then the *superba* variety must be obtained, for there are some two and three flowered varieties of the ordinary type which no amount of care and culture will cause to produce more than three flowers on a spike. In conclusion let me draw the attention of Orchid-loving amateurs to *Disa macrantha*, which bears flowers as large or larger than *D. grandiflora*, and its varieties vary in colour from nearly white to deep rosy-crimson. The plant is already introduced and has flowered in the collection of an English amateur.—B.

GARDENING FOR THE WEEK.

Stove.

The generality of stove plants will now require a change in their treatment. The different species of *Medinilla*, the growth of which will be about matured, should now and through the winter receive no more water than is just sufficient to keep the leaves from flagging. All stock required to go more or less to rest must have further growth discouraged by a drier condition of the roots, as well as less moisture in the atmosphere, giving more air, and dispensing with shading altogether; but with this the mistake often committed in the cultivation of stove plants, of reducing the temperature too much, must not be made; it certainly checks growth, but is anything but the right means to bring about the maturing process essential to free-flowering next year. Along with this treatment I should not recommend syringing being altogether discontinued, for where this course is followed it often happens that red spider makes its appearance even so late in the season as this; but in the syringing now performed it is not well to resort to the slight daily sprinkling sometimes given, than which it is much better to syringe freely two or three times a week, getting well to the under sides of the leaves where spider and the small yellow thrips so troublesome in stoves generally conceal themselves.

Dipladenias.—To make the most of these, that is to grow them in a way that will afford flowers for cutting over the longest period of the year, they must have no further rest than that which they get through the slower growth that is made during the winter. I have kept the same plants on for a dozen years, as strong and healthy at the end of the time as they were at the commencement, with very little rest during the whole period. I simply allowed them to get quite dry about this season of the year, and then at once cut them back to within a few joints of where the shoots had been shortened to the year preceding; then in the course of ten days, when the buds had got prominent, but before they had broken into leaf, I turned them out of the pots, shaking nearly all the soil away, and reduced the roots to something like the condition of large *Dahlia* roots when lifted in the autumn, a considerable portion of the small fibres being thus cut away. I then repotted them in peat and sand, the former containing almost as much fibre as the material in which *Orchids* are potted, say *Cattleyas* or *Dendrobiums*. I have not found it possible to keep *Dipladenias* in a healthy thriving condition for any length of time without this yearly renewal of the whole of the soil, and I have also found it much better to carry out the operation at this season of the year than defer it until spring, for, although they break weakly at first, consequent upon the loss of root fibres, yet they have plenty of time to gain strength through the spring, and they bloom much earlier than when they are then removed. The pots used will not require in the first instance to be more than half the size of those which they have occupied during the summer whilst flowering, as towards February or March, when the roots have pretty well filled the soil, they can have another shift, which may be given without their receiving any check. They should be kept with their shoots close up to the roof, and at the warmest end of the house. Where there is only just sufficient warmth maintained to keep them alive during the winter, it would not be safe to pot them at all at this season.

Allamandas.—These may be had in flower almost all the year round by the use of several plants, encouraging some to make growth and flowers all through the latter months of the year, and drying one or two specimens off about this time. To effect this it is needful to let the soil get much drier than many plants would bear, allowing them to flag severely before any water is given, and then only administer enough to moisten the soil very slightly, for such persistent growers are they when in sufficient heat that if the soil is moistened to the extent that other plants need they scarcely can be induced to rest at all. From this time forward during the autumn months, plants to be thus early put to rest must have no more water given to the roots than will prevent the leaves from shrivelling whilst in a green state.

Clerodendrons.—The climbing species of these are so manageable that, where a sufficient number exists, they may be had in flower from March up to the middle of August. But this wide range in the time of their blooming, as a matter of course, necessitates their making growth at different periods; for, flowering as they do from the ripened wood, whatever cutting back is needed should be done immediately after blooming and before the plants start into growth. Those that flowered early will, in the course of a few weeks in most cases, have made as much growth as is necessary, when they may be prepared for resting by withholding water, much in the same way as in the case of *Allamandas*. The young shoots from the first having been all along kept trained close to the roof, the naturally hard character of the wood formed under such conditions is very

conducive to free-flowering. Plants that bloomed later will be proportionately later in making growth, which they may be kept on making up to the end of the year. I have found that this late growth will flower just as freely as that made earlier, provided that whilst it is being formed the points of the shoots are kept close up to the glass.

Streptocarpus biflorus and **S. Saundersi.**—Those who have a good stock of these plants, which individually occupy so little room, and bloom over such a lengthened period, possess two of the very best subjects having pale blue or lilac flowers for cutting in existence. I know of no arrangement of cut flowers, either bouquets, vases, or baskets, in which they are not alike effective; they stand better than most stove subjects, afford a good length of stalk, and combine well with almost any other colour of flower with which they may be associated. I have found them to do better in small, say 6-in. or 7-in. pots, than in larger ones, and when any that have formed a number of crowns begin to want more room than pots of the size just named, it is better to divide them. They will bear this now quite as well as in the spring, for their cultivation is in every way as easy as that of a *Gloxinia*, but, being evergreen, they keep on growing slowly all the year round, where sufficient warmth is present to enable them to do so. Independent of their use in a cut state, they are amongst the most effective small-growing plants for intermixing with other stove subjects set on side stages.

Gardenias.—If all the stock of these show a disposition to set their flowers, a portion may be removed to cooler quarters, giving those that are wanted to bloom earliest more or less heat, according to the time at which they are required. Where a sufficient stock is at command they may be had in flower the whole year round, by treating them so as to make growth at different times, and varying the management with different portions so as to bring them on in succession.

Achimenes, Gloxinias, and Caladiums.—The season has now arrived when most of these will require drying off, a process which should be done gradually, keeping all in sufficient warmth so as to admit of full development of the roots previous to the leaves dying quite off. This is best secured by withholding water by degrees, the plants during the interim being in a somewhat reduced temperature, but not lower than is necessary to induce a cessation of growth.

Forcing Houses or Pits.

In the erection of garden structures now there appears to be a general disposition to put up houses of a larger size than hitherto; and if they are kept only moderately large they have much to recommend them, as, whether for stove or medium-heat requiring plants, they do not fluctuate in temperature so quickly either in summer or winter as small houses; but for keeping up a supply of forced flowering plants through the winter, low, not over wide structures are much the best, regulating the length according to the amount of work to be done, with, if possible, a division, so as to keep one end cooler than the other. This latter arrangement should always be present where a large and continuous supply of cut flowers is wanted in winter, especially with a view to having as much variety as possible. Where means of this description do not exist a large reduction in the number of different subjects that can with advantage be used for the purpose is necessary; for some require much more heat than others will bear, and in forcing it is of the greatest importance that none are submitted to more heat than is necessary to bring them on into bloom in a way that admits of their flowers possessing a stout, sturdy character, without which they are of comparatively little value, either where the plants when in bloom are required as decorative objects or the flowers are wanted in a cut state, as when any have been in more heat than they like the bloom never lasts nearly so long, nor can be used without flagging to an extent that renders it of little use. I allude to this matter more particularly from the frequency with which places are met in which large quantities of flowers are expected all through the winter, and yet there are no means of forcing them with the exception of a single house wherein are grown permanently a large number of plants requiring a high temperature, or the structure may be principally filled with plants of an intermediate character needing less heat. Under such circumstances any attempt at forcing a promiscuous collection of the usual winter-flowering plants needing in themselves considerable difference of heat can never be more than partially successful. Where there happens to have been a couple of houses devoted to the cultivation of *Melons*, or something of a like character, these will generally be found just the places for the winter forcing under consideration, and they should at once be prepared for that purpose, and the plants to be forced should be immediately moved into them from the pits and other places which they have occupied during the summer. The whole stock ought to be at once placed where they can be kept sufficiently warm to prevent their suffering, which invariably

takes place when this class of plants is kept too cool, when the solar heat is so much on the decline and the nights get long and chilly. These winter-bloomers should be gone over and the best matured portion selected for bringing into flower first. These will ordinarily be found to consist of the older cut-back examples of Poinsettia, *Thyracanthus*, *Sericographis*, *Scutellaria Moccimiana*, *Euphorbia jacquiniaeflora*, *Eranthemum*, *Plumbago rosea*, and others, that usually are better calculated to bloom before those that have been grown this season from cuttings, and which may be kept anywhere where enough warmth is at command to just keep them in a slow, gently-growing, healthy state. There is no season of the year when it is so necessary to keep the plants that are being brought into bloom with their heads near the glass as winter, for however light the structure they occupy may be, the closer they are to the roof the more satisfactory will be their blooming. Where there is a place at command that can be kept somewhat cooler as already described, such plants as tubercous *Begonias*, treated for late flowering, *Salvias*, *Pentas carnea*, and the like, may be transferred to it.

Guernsey Lily.—This very serviceable easily managed autumn-flowering plant is much less used than it deserves to be. Where a few dozens are grown and now placed in a brisk heat they will quickly throw up large heads of red flowers that have a handsome appearance on the plants which may be used when in bloom for the decoration of warm conservatories, and they are equally valuable in a cut state when mounted in the form of single flowers.

Brunsvigia Josephinæ.—This nearly allied plant is in every way quite equal to the above; there are two or three forms of it, all with red or scarlet flowers, that bloom through the autumn months with similar treatment, and they are far more beautiful and useful than many of the plants now more extensively grown.

Roman Hyacinths.—In the whole range of bulbs for forcing there is nothing more useful than these for the production of flowers towards the end of the year; although they do not afford the diversity of colour furnished by the larger growing Hyacinths, yet it is much better to grow a portion of them than to attempt the forcing of the larger flowered kinds very early, as the Roman varieties come in with little difficulty. They consist of white and blue, the blue being not quite so early as the white. They do not occupy much room—a 6-in. pot is sufficient for half-a-dozen bulbs—or they may be grown in pans a dozen or a score together, according to the size of the pans used. The soil, drainage, and general management do not differ from those employed in the case of ordinary Hyacinths.

T. BAINES.

Flower Garden.

Auriculas.—I have just read the remarks of "Brookhurst" (p. 234) on the Auricula. He has not had so much experience as Mr. Horner, but still if he finds the second week in June the best time for the neighbourhood of Manchester he would be wise to repot at that time, and others similarly circumstanced may make a note of it. I do not quite understand what "Brookhurst" means by the "melancholy results of my early potting." All I said was that there was an autumn bloom, but that the latest potted plants showed the largest percentage. I also found last year that the July and August plants were not so well rooted as those potted earlier, but I have potted Auriculas at all seasons with good results. With many growers a great deal depends upon the time that can be spared for that operation. If more necessary work needed attention I would do that first; at the same time it is well to say what one considers to be the best time for potting. Our plants up to the present time have been behind a north wall, but they will be moved from there during this or next week. In the south it is necessary to place the frames behind a north wall. The ground on which they are to be set must be well sprinkled with dry lime to destroy slugs, and all the woodwork of the frames must be washed clean.

Carnations and Picotees.—These do not at present demand any more attention than to see they do not suffer from want of water. It is easy to neglect plants out-of-doors during a period of dry weather, but if allowed to become too dry considerable injury is the result; the small roots that are forming at their callus die, and the plants are permanently injured. See that pots containing layers are fully exposed in an open position, but still they should be protected from the strong gales which are often experienced at this season from the south-west.

Hollyhocks.—The weather which we are now having just suits the Hollyhock; the heavy dews at night quite saturate the flowers, and they are also drenched by occasional showers; but there is enough sunshine and drying winds to thoroughly dry them every day. It is continued wet for a few days that injures them most, causing the flowers to become mouldy. We would still put in any cuttings that can be obtained from the base of the plants; or eyes got from side growths from the main stem. Let all flowers with the seed-pods be removed, as they show decay if seed saving is not in-

tended. The best-named Hollyhocks have become rather scarce, therefore it is necessary to try to obtain as much stock as possible.

Pansies.—We are just now putting in cuttings of these, and it may be well to again remark that the thick, pithy flower-stems are useless for cuttings. The best are the slender growths that usually come up thickly from the base of the plants when the old stems have been pegged down or removed. These can be pulled out with plenty of small rootlets attached to them, and when carefully put into boxes in fine soil they speedily start into growth. A reddish-coloured aphid usually attacks them at this season, but it can be destroyed by dipping the cuttings in soapy water before they are inserted.

Polyanthuses.—The seeds were very late in ripening this year, but we were successful in saving a few good pods. The seed comes up in about a fortnight, and in another fortnight the young plants may be pricked out in boxes or pans. Beds of seedlings or named varieties should be kept quite free from weeds by stirring the surface of the ground occasionally with a Dutch hoe. Plants in pots are now well established and must be well attended to with water, removing any decaying leaves and occasionally stirring the surface soil. Red spider frequently attacks the under sides of the leaves and is not perceived until they begin to turn yellow. It can be destroyed as well as green fly by dipping the foliage in soapy water.

Pentstemons.—These are now very gay in herbaceous borders and they will remain so for a long time. Few of our hardy flowering plants continue to brave the wet and cold so long as these do; it is, however, necessary to remove the seed pods as the flowers fade, as they seriously cripple the energies of the plants. The stems must also be supported with sticks as they require them. Cuttings may be put in now if a large stock is required, but we prefer to wait until October.

J. DOUGLAS.

Indoor Fruit.

Vines.—The season, as far as weather is concerned, is of such an exceptional character that special means must be adopted to ensure the thorough ripening of both Grapes and wood. With us, all late grapes are colouring well, but, strange to say, the wood does not change proportionately to that beautiful nut-brown tint which indicates full maturity, therefore we are firing harder than usual in the hope of effecting by this means that which is otherwise unattainable through lack of sunshine. Vigorous young vines cannot possibly mature their wood without a free allowance of artificial heat, and of course the stronger the growth the more difficult they are to ripen; no time should therefore be lost in applying such heat as shall ensure full ripeness at the earliest period. Free ventilation should ever accompany the application of fire-heat that is used for ripening the wood, and the growths should now be kept stopped, but the principal foliage should be sacredly preserved and left to die off naturally. Do not allow inside borders to want water, even though the Grapes are ripe, if there is any fear of their shrivelling from want of it; better sacrifice a few by damp than that this should happen. After watering, either cover the border with mats or dry straw, both for the sake of neatness and in order to prevent rapid evaporation. The earliest Vines, on which the Grapes are to ripen in April and May, should be pruned at once, the borders renovated, and the houses cleaned, or if they are to be painted the present is the best time to do it. Outside borders of such Vineries should now be protected from further rains, either by means of shutters, tarpaulin, or thatching.

Peaches and Nectarines.—In early and mid-season houses, lift and replant any trees that are not satisfactory, either from growing too vigorously, or not sufficiently so. With careful manipulation such lifting will not militate against fruit production next season, but there must be no unnecessary mutilation of the roots, and especially all the fine fibrous roots must be preserved. The drainage should have particular attention, as the remotest approach to stagnation is soon resented by the trees. The best soil is a calcareous loam of medium texture, intermixed with a small proportion of charcoal and lime scraps; should it be very heavy, then add a larger proportion of both charcoal and lime scraps, making the whole moderately firm in order that a certain amount of resistance may be encountered by the roots, a condition which induces the production of lateral rootlets. Late houses, as soon as cleared of fruit, should have all shoots thinned out that are not required for the furnishing of the trees or for next year's fruiting, the space thus gained being an invaluable aid to the ripening of the wood. Still syringe the trees, to keep the foliage clean to the last, and let inside borders be as freely supplied with water as during the earlier stages of growth.

Melons.—Increased artificial heat both top and bottom will now be necessary to keep these in vigour, and the fruit must have the fullest exposure to light by tying aside any foliage that intercepts it. Though less water will now be necessary than earlier in the

season, avoid dryness, which is a sure precursor of loss of foliage and consequent insipidity of fruit. Free ventilation, full exposure to light, and an equable bottom heat never fail to ensure fruit of high flavour. The blooms of late plants should be fertilised, and as the advanced season renders this crop somewhat uncertain it will not do to wait for a number of flowers to be ready to fertilise at the same time; on the contrary, the first that appears should be set. Keep the shoots thin, and those producing fruit should be stopped at the first joint beyond the fruit. As soon as all are set encourage quick growth by closing the house very early. With sun-heat, the temperature may advantageously be raised to 90 for an hour or two.—W. W.

Kitchen Garden.

It really appears as if there is to be no cessation with regard to the unsettled weather that has so long prevailed, and which has rendered all garden operations difficult to perform, and which still taxes both our patience and time to the utmost as regards any endeavour to keep down weeds and to get the ground well cropped for the winter. There is also, I fear, another and greater trouble in store for us, and that is, the growth made by all winter vegetables and salads is necessarily of so sappy a description, without sun to harden the tissues, that in the event of a winter of but even the average type setting in they are sure to suffer greatly, if, indeed, they survive at all. With such gloomy prospects the forcing of vegetables should have extra and early attention. Tomatoes do so well in pots, and accommodate themselves to almost any temperature above actual freezing up to 70°, that in most gardens a place may be found for a few to be kept growing throughout the winter. Where there are heated pits or spare spaces in Cucumber and Pine pits, French Beans are easily produced, and a good quantity should be got in at once; for this purpose there is no better kind than Osborn's, though that fine variety Canadian Wonder forces at this early season tolerably well, but it requires more space than Osborn's. Mushrooms and Cucumbers will, as a matter of course, be in great request, and provision should be made for their production accordingly. Seakale is yet in vigorous growth, but the first sharp frost will stop that, when a first batch of roots may be lifted for forcing. Due allowance, both as to produce and time required for forcing, must be made for immaturity of the crowns. In order to induce rest to the crowns of Asparagus that are intended for forcing earliest, cut away the stems to the ground line; these are still in such active growth that no attempt at forcing should be made for at least another month. Lettuces and Endive intended for winter use should have the protection of frames whenever frost seems imminent, for in order to prevent decay the first frost must be avoided. Parsley and such other herbs as are in daily request throughout the winter should have immediate attention; the former, as a rule, winters safely on a dry south border, but a frame placed over it ensures its safety in all weathers. Basil, Tarragon, Balm, and Mint, are all easily produced in any warm position in houses or pits, and if planted in pots or boxes, they can be conveniently removed as required from one place to another. On fine days, and when the leaves are dry, tie up Endive and Lettuces to blanch, and all herbs not yet cut for drying should in like manner receive attention. Celery should also be earthed up under the same conditions as to weather, but previously remove all outside suckers, and prevent the soil from getting into the centres of the plants, either by tying or holding the stems closely together whilst the soil is being placed around them. Winter Spinach should be well thinned out, certainly to at least a foot plant from plant. Canker is sometimes very injurious to this crop, and with the view of warding it off there is nothing better than keeping the surface soil loose, and taking the precaution to sow only on well drained ground. Continue to earth up Broccoli, Sprouts, Cabbages, &c., as occasion requires, and let no opportunity slip as regards killing weeds. Cauliflowers may require to have their leaves bent over their heads to evade frost, which may now occur at any time. W. W.

Extracts from my Diary.—September 23 to 29.

FLOWERS.—Potting old plants of Iresine Lindeni for stock, and Pelargoniums for winter blooming. Potting Fuchsias and tying Chrysanthemums. Potting Ageratum for stock. Moving Pelargoniums from cold pit to a house prepared for them. Re-arranging plant houses.

FRUIT.—Cutting out shanked berries from Muscat and Trebbiano Grapes. Removing lateral and superfluous shoots from Vines in late Vinery to admit light. Placing boards under Melons swelling. Gathering Cockle Pippin Apples, and storing them in fruit room. Trenching up north border, preparatory to planting Gooseberries for late use. Gathering Bedfordshire Foundling Apples and Winesour Plums. Gathering King of the Pippins, Blenheim Orange, Court Pendu Plat, Round Winter Nonsuch, and Claygate Pearmain Apples. Gathering Marie Louise Pears.

VEGETABLES.—Tying winter Cucumbers. Sorting Paterson's Victoria Potatoes in pits, and reclamping those for eating. Gathering Scarlet Runners. Earthing up Celery requiring that attention. Tying and stopping winter Cucumbers, and top-dressing them with rich compost. Planting Daniels' Defiance Cabbage on well-manned ground. Top-dressing Tomatoes growing in houses for fruiting in winter, and stopping shoots at each bunch of fruit.—R. GILBERT.

THE KITCHEN GARDEN.

MAJOR HALLETT'S PLAN OF STAMPING OUT THE POTATO DISEASE.

ASSUMING the letter published in the *Times* lately by Major Hallett on the Potato disease to contain an accurate statement of facts, I think the subject should not be lost sight of. In his letter, Major Hallett says, omitting some details—"Disease is as much hereditary in plants as it is in man. So long as unhealthy seed shall be planted so long will our Potato crops be specially liable to disease, just as in like manner a person of weak constitution at once succumbs to surrounding conditions which do not affect the strong and healthy. Acting upon this view, I have for years carefully selected my Potatoes for seed, and upon the assumption that the disease reaches the Potato through the haulm, have always rejected the whole of the produce of any plant which represented any appearance of disease; and although this may have been manifested on only one of its forty or fifty Potatoes, and even on this but slightly, I have rejected them all as of 'tainted blood.' The practical result has been an almost complete immunity from the disease."

In the *Times* of February 2, 1877, Dr. B. W. Richardson is reported as having said, "It took three or four generations to wipe out the hereditary tendency to disease." If this can be effected in the case of man, where we do not possess the advantages of the stamping-out system, then twelve generations may have gone a long way towards wiping out in my Potatoes such hereditary tendency to disease; and by continuing the annual selections I hope and believe that not only will this be fully "wiped out," but that the very opposite, hereditary tendency to health, will be firmly established. The value of each successive selection, even the latest, was most strikingly exemplified this year of almost universal blight when digging up the crop. Of the Kidneys, every one of the Potatoes descended from plant "A, 1878," was absolutely free from disease, while only 2 ft. off, in the very first row of the descendants of "B, 1878," there were found four diseased tubers, and in the other rows six more; but this was only ten in a quantity sufficient to plant one-sixth of an acre, our consumption of each variety. Well might my man exclaim, "There can't be much doubt about selection after this." So, too, with the Regents in another part of the garden: the whole of the produce from "A, 1878" was perfectly healthy; of that from "B, 1878," only one plant affected in one of its tubers only, and that but slightly.

What I attach most importance to are the results of Major Hallett's experiments, which were carried out at his place near Brighton. If he has succeeded in stamping the disease out of his own crops, or nearly so, and in the midst of disease-affected plantations, and is prepared to vouch for the fact, his statements deserve more than a passing notice. I would suggest that his experiments be extended, under the auspices of the Royal Agricultural Society, for example, which has already practically interested itself in the subject of the Potato disease. It would be desirable that the seed from the Major's selected stock be tried in different parts of the country on different soils. I believe I am not mistaken in saying that the "selection" experiment has been suggested if not tried before, but never carried on for a sufficiently long period to test its value, and cultivators have contented themselves with selecting sound, or apparently sound, tubers only; but it would appear from Major Hallett's letter, that he also rejected tubers from plants "which represented any appearance of the disease," thus making assurance doubly sure; and that his experiments have extended over a period of about twelve years. J. S. W.

The Centennial Potato.—A curious circumstance regarding this Potato occurred here which some of the readers of THE GARDEN may possibly be able to explain. About a dozen tubers were cut in halves in spring, and planted side by side with some twenty or more other kinds, all of which latter came up well and grew rapidly, whilst the Centennial had not produced the slightest signs of growth up to the middle of August, at which time on being examined the sets were found to be perfectly hardy and sound, but the eyes did not show the slightest symptoms of growing. Does this Potato behave in this way elsewhere?—K. LANGLEY.

POTATOES EXEMPT FROM DISEASE.

THE comparative immunity from disease of certain kinds of Potatoes is this year a matter of the first importance. It would be difficult to recall a season so fraught with mischief to the Potato crop as this present one has been, and Potato growers would do us great service if they would give the names of some half-dozen or more sorts, if they have as many, that stand out beyond all others comparatively clean and healthy. The phrase "disease proof" is perchance a misnomer as applied to any kind, but some kinds are more or less disease-resisting. We have through upwards of thirty years' experience become so accustomed to losses in the crop year after year that we think ourselves fortunate if not more than one-third of the crop is rotten. If, however, there are any kinds that do not this year, and as a rule in other years, show as much disease as that, indeed have only one-fourth or less affected, or perhaps so few diseased as to be unworthy of notice, then these may well claim to be regarded as disease-resisting. My own experience this year extends over some eighty kinds, and generally is more favourable than is that of gardeners who grow their Potatoes in rich garden soil; the richer the soil, as a rule, the more destructive the disease, and as a consequence, the less the soil is enriched the less are Potatoes diseased. Thus my own sorts grown in the open field in fairly open, porous land, and with plenty of space between them, have had no manure applied to the soil for two years other than patent manures, and although these will induce growth in the plant, such bad results rarely follow as are seen where raw manures are used. On this land I have had much less disease than many others have found, but there has perhaps been less size; still, this year's crops varying from 40 lb. to 50 lb., good, clean tubers, on rows 50 ft. in length, have left little to complain of. My cleanest kind has been *Magnum Bonum*, of which there has not been, so far as lifted, a single diseased tuber. Next came *Advance*, a seedling, so said, from the *Victoria*, but bearing a close resemblance to *King of Potatoes*, of which I anticipate it will prove to be but a fine form. *King of Potatoes* was also very good indeed, the proportion of disease being about one-tenth. In the same category must be classed the new purple kind *Vicar of Laleham*, a seedling from the *Victoria*, and a remarkably fine cropper. In poor field land without manure this is throwing a pure, clean tuber sample of good quality. *Early Purple*, a longish, purple Potato, has also proved comparatively clean and good. Then came *Triumph*, a round, red, American sort, not large at any time, and perhaps to that feature is owing some of its immunity. The *Early Rose* was very fairly good, as also was *Trophy*; this latter throwing a fine crop, but the quality is indifferent. *International* gave a great crop of medium-sized tubers with but few diseased; so also did *Schoolmaster*, and *Radstock Beauty*, a Potato fit for any table, was but moderately hurt. The best and cleanest crop of all the *Ashleaf* family was given by *Lemon Kidney*, not a score of tubers out of a bushel being diseased. These are enough to name, although others could be specified as fairly good. Should others give their experience of sorts, and out of their many kinds give a list of a dozen that have stood with them best, it will doubtless be found that experiences of sorts vary very much; still any one or two sorts getting frequent favourable mention should specially deserve more extended cultivation. As a rule, I find sorts having stiff, erect haulm the least affected, and further believe that this feature is one of great importance to the future of the Potato. I think it will be found that the more woody the plant stems, the less able is the disease to travel to the root-tubers.

A. D.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Forwarding Globe Artichokes in Pots.—What an advantage it has been to those who have had the means of preserving a few old roots of *Globe Artichokes* in pots or boxes somewhere under glass this season. Although in most situations *Globe Artichokes* are hardly enough to stand our climate, yet when an exceptionally severe winter comes, all the growth near the surface is cut off, and late in spring when the plants struggle through, they have hardly strength enough to bear fine heads, and they are so late in addition as to detract much from the usefulness of the crop. Early in November is a good time to lift a few roots, or at least some time before frost comes. They may be placed anywhere in a cool house where frost does not enter, and have sufficient water given them to keep the roots just moist. Early in April the roots may be divided and planted out. I grant the crop in all seasons may not be superior or, indeed, much earlier than those left in the ground; but then it will be so convenient to have *Artichokes* in a difficult season when they are scarce everywhere. Another way is to plant a few strong suckers in single pots, and grow them on steadily through the winter near the glass in a house where a little fire-heat is used, shifting into larger pots as required, and hardening off and planting out finally in April,

or when the weather appears settled and suitable. *Globe Artichokes* must be well fed; their large succulent leaves and stems require a good deal of support, and not only is a deep and well-enriched soil necessary, but mulching and watering should not be neglected.—E. H.

Cucumber Disease.—Early in the spring this year I made a hot-bed consisting of stable manure on which I placed a frame for Cucumbers. Some of my *Cucumber* seed failing I got a couple of plants from a friend to fill the frame. I had heard that my friend had the *Cucumber* disease in his house these last two years, but not knowing the character of such a disease I did not take much notice of the matter at the time, but I knew something about it when too late. The plants went on well, considering the bad dull weather which we have had, till I cut two or three fruit; and then I saw the *Cucumber* disease for the first time, a circumstance that will make me very careful in future where I get my *Cucumber* plants from. I have not had a fruit out of my frame since. I also sowed some *Ridge Cucumber* seed in the same frame, and in order to harden the young plants off I placed them under a handglass, on a bed which I made up for *Vegetable Marrows* some 20 ft. from the *Cucumber* bed. After a time the *Ridge Cucumbers* were planted out, but only to share the same fate as those in the frame. I have not had a fruit from them, and they look as if they had been scorched by fire and battered by hail, and now the disease is appearing in the *Vegetable Marrows* on the same bed on which I placed the *Ridge Cucumbers* to harden. The *Vegetable Marrows* nearest the handglass that contained the *Ridge Cucumbers* are much more diseased than elsewhere, the former gummy like the *Cucumbers*. Having no *Cucumbers* for the table or for pickling and no *Marrows* for the kitchen is a great loss. For all these disasters I fear there is no cure. I have since made another bed about 40 yds. from the first, and have the *Telegraph* kind coming into bearing on it raised from seeds obtained miles away, and I hope to be able to cut a few fruit out of this frame before the cold weather sets in. At the present time they look well and healthy. I may add that I have not destroyed the first lot, as I want to see whether or not the disease can be carried about as I read in the *GARDEN* it can be. Since writing the above I now notice the same plague in my second bed, so all is over with my *Cucumbers* this year.—R. G.

Hathaway's Excelsior Tomato.—This is a very useful variety, being large in size, smooth and even in outline, and a good cropper. We have grown it largely under glass this year, as the outdoor culture of *Tomatoes* is simply labour lost, the disease attacking them before they attain any useful size. This year we had those under glass severely attacked during the early part of the season, when the weather was wet and dull, but since clearer skies have prevailed the same plants have grown away perfectly clean and healthy, and are now ripening good crops. It is therefore advisable to grow so useful and remunerative a crop in a house or pit exclusively devoted to it when a dry, buoyant atmosphere can be maintained, as even under glass there is no exemption from disease if there be much atmospheric moisture. Fortunately, the *Tomato* flourishes well under rather excessively dry conditions, or such as would be sure to induce red spider on many plants and fruits, and is even more fruitful than when grown more luxuriantly, as, like the *Fig*, its strong-rooting propensity enables it to live and grow vigorously where tender-rooted subjects would fail. I have no doubt that *Tomatoes* would be a more remunerative crop to grow for market than *Cucumbers*, as, since outdoor crops of them have failed, those ripened under glass realise good prices. After trying several sorts I think there are few that will surpass *Hathaway's Excelsior*, either for colour, size, or flavour.—J. GROOM, *Linton Park, Moulstone*.

Preparing Broccoli for Winter.—The damp and almost sunless season which we have had has produced rapid growth in the *Brassica* tribe to which a check must at once be given, so as to ripen or harden them against severe weather, more particularly *Broccoli*, which forms our principal vegetable for the beginning and end of the year. It is a good plan to run the spade 9 in. or 10 in. deep into the soil down each side of the plants. About 6 in. from their stems cut off a portion of their roots, thereby inducing the plants to form sturdy growth, which is essential to the production of good heads and sound keeping during the next month. *Broccoli* should be layered by taking the soil out a spade deep up the side of the row, dropping the plant into the opening with the head to the north. Any loose manure from the surface of the *Vine* borders, or *Grass* cut from the lawn, thrown in amongst the roots before filling up with soil, induces them to strike quickly into the fresh material, thus adding strength to the plants and size to the heads. If a sheltered position in any other part of the garden, open to the south, is at liberty, they may be removed to it on a hand-barrow, and if the roots have been cut down the sides with a spade, as alluded to above, a fortnight or so before

lifting, a too severe check is prevented, which otherwise might cause the outside leaves to turn yellow and weaken the plants. In severe weather some dry litter or Bracken placed amongst the plants afford a good protection for the heads.—JAMES SMITH, *Waterdale*.

indeed is, superlatively hardy. Fig. 4 is a more robust and taller grower, partaking, both in style of growth and foliage, of the character of the Brussels Sprout, and is of equal value as a winter Green. W. H.

ORNAMENTAL KALES.

THERE are now so many varieties of vegetables, salad plants, and herbs that are at once both useful and ornamental that for any one so inclined it requires the exercise of but little ingenuity to make a kitchen garden as full of interest from a decorative point of view as any other department of a garden. As dark green bordering plants,

ASPARAGUS CULTURE.

(Continued from p. 250.)

DIFFERENT METHODS OF GROWING ASPARAGUS.

As we have already said, Asparagus may be grown in a variety of ways—in square or oblong beds, or in borders under a wall, in separate stools, or isolated plots.

Fig. 1.—Curled Dwarf Kale.

Fig. 3.—Palm Kale.

Fig. 4.—Moellier's Kale.

Fig. 2.—Sprouting Kale.

there are Parsley-curl'd Eudive and Lettuces, whilst as secondary contrast lines there are the bronze-leaved Beets, and green Fern-like foliage in Carrots, whilst in the large variety of Kales or Borecoles—green, coloured, and parti-coloured—there is a rich store of suitable material for ornamentation. The annexed illustrations represent varieties, not only useful in a decorative point of view, but profitable winter esculents. Fig. 1 is the ordinary dwarf Scotch Kale, so well known and appreciated by everybody. Fig. 2 is not so well known, but is of a far more profitable character, producing in profusion sprouts of the most delicious flavour throughout the hardest winter. In fig. 3 we have simply a tall and but slightly curled variety of Scotch Kale, and probably a selection from what is generally termed Cottagers' Kale, a variety that is much grown in the Northern Counties of England, and which is considered to be, and

In Square Beds.—This is the mode of culture which has just been described, and consists in opening a number of trenches side by side with each other at a distance of from 3 ft. 3 in. to 4 ft. 9 in., according to circumstances.

In Oblong Beds.—We have also spoken of this method of culture, which consists in planting two rows of Asparagus side by side, leaving a wide empty space between them, so that the roots which spread out very widely may not become entangled or live at the expense of each other.

Wall Borders.—We may grow Asparagus on wall borders, in lines between the Vines in a Vineyard, or between

espaliers. With a northern exposure we shall get a late crop, with a southern an early one.

Separate Stools.—We may also grow Asparagus in single stools in Vineyards in corners, in fact, wherever a piece of ground is to be found upon which the sun shines. Asparagus grown thus continues to bear for a long time, and in no way yields to that grown in square plots. Most of the Argenteuil Asparagus is grown in isolated stools in Vineyards.

In Clumps.—In newly-planted orchards we may plant between each tree a clump of eight stools, which will yield good crops for fifteen years. The manure and cultivation given to the Asparagus helps the neighbouring trees. Thus we may increase our fruit crop and grow Asparagus at the same time.

Each of these methods has its peculiar advantages. Planting in the open square bed allows us to choose the most favourable situation for growing the plant without disturbing the harmony of our ordinary kitchen garden, but the yield is not so good and the plantation does not last so long. In the long-bed system we may grow Asparagus nearly anywhere, and thus destroy the symmetry of our kitchen garden, injure the neighbouring crops, and increase the difficulty of gathering, by reason of the large extent of ground to be traversed by the labourer. If we plant in wall borders we often utilise ground which otherwise would be very often lost, but with a southern aspect we must take care to plant at a distance of at least 10 in. from the foot of the wall. With a northern, western, or eastern aspect we can plant in the plot at a less distance. In the isolated stool system we may obtain very fair results in well ventilated situations. In Vineyards, for instance, we may obtain large crops of Asparagus of excellent quality. It is by adopting this method of Asparagus growing that the Argenteuil growers obtain such fine results both in the way of the natural product and the pocket. These isolated stools cost but little to establish, and last for a long time. We have seen stools twenty-eight years old, which still gave excellent crops. On the clump system, when planted amongst tall trees, we may gain great advantages from this mode of culture. As yet it has been but little practised, but we strongly recommend it, on account of the excellent results which it yields. It may easily be conceived that if we grow Asparagus at the foot of a tree, digging, hoeing, and weeding are unnecessary, and that these isolated clumps will furnish large and good crops for many years, especially in those places which have been dug deeply for the reception of trees, or where new soil and manure have been laid down for the same purpose, and that without in any way injuring the neighbouring trees, which themselves in turn profit by the care bestowed on the Asparagus, as well as by the manure with which it is dressed from time to time.

COST AND YIELD OF A HECTARE (2½ ACRES) PLANTED WITH ASPARAGUS AT ARGENTEUIL.

Opening the trenches, making the mounds, planting the stools at the rate of 100 stools per working day, at 4s. 2d., or £2 per thousand for 10,000 stools	£20
10,000 stools at £3 12s. per 1000	36
Carriage and sundries, say	4
	£60

By spreading this sum over twenty years, the average life of a plantation, we have per annum	£3
Rent of one hectare of land at 2s. 4½d. per acre, say	12
Labour, one hectare, say	14
Manure, per annum	14

Cutting, pulling, bundling, carriage to Paris market	40
Sundries, say	3
	£86

The medium yield of each stool is half a bundle, which for 10,000 stools would be 5000 bundles, at say 1s. 7½d.	£400
Deduct for bad crops, damage, &c.	60
	£340
Expenses	86
	£254

counting twenty years of full crops, for although we only begin to pull at the end of three years, the stool is just as likely to last twenty-four years as twenty. We have also not taken into consideration the choice early bundles, which often sell for 12s. or 15s. at the beginning of the season instead of 1s. 7½d., besides which we must deduct the expenses of gathering for the first three years.

COMPARISON BETWEEN DUTCH & ARGENTEUIL ASPARAGUS.

A great number of persons do not yet seem to properly understand the difference between the Argenteuil Asparagus and that of other celebrated localities. The following are some comparative calculations which will enable them to judge of the merits of the case. The experiments of which the figures are the outcome were made on thirty-five stools of the same age of each variety. The plants were reared in the same soil and were seven years old, the gatherings being made under precisely the same conditions.

ARGENTEUIL ASPARAGUS. (Early.)	DUTCH ASPARAGUS.
First gathering made April 3.	First gathering made April 20.
Produce of a single stool during forty-two days—29 heads, weighing 1540 grs. (say 3 lb. 6½ oz.).	Produce of a stool during forty-two days—24 heads, weighing 605 grs. (say 1 lb. 5½ oz.).
Prices at the market rate in the Paris market.	Prices at the market rate in the Paris market.
1540 grs. (say 3 lb. 6½ oz.) represents half a bundle, a good bundle weighing from 3 kilos. to 3 kilos. 200 (say 6½ lb. to 6¾ lb.). Amongst these heads there were ten small, eleven medium, and eight large, which taken at the ordinary price would have sold at the rate of 3 fr. (2s. 4¾d.) per bundle, or 1 fr. 50 c. (1s. 2¾d.); but as the latter do not fetch so much as the former, this price must be reduced to 1 fr. (9½d.)	605 grs. (say 1 lb. 5½ oz.) represents about the fifth of an ordinary bundle of from 3 kilos. to 3 kilos. 200 (say 6½ lb. to 6¾ lb.). The heads were none of them very large. There were eight very small, ten medium, and six somewhat large. The ordinary price for a similar quality would be 1 fr. 50 c. per bundle (say 1s. 2¾d.); the value of the crop would therefore be 30 c. (3d.).

Wishing to push our experiments farther, we undertook an investigation into the quantity of eatable substance contained in each variety, with the following result. We first of all weighed out 1400 grammes (3 lb.) of Argenteuil and Dutch Asparagus, that is to say,

ARGENTEUIL ASPARAGUS.	DUTCH ASPARAGUS.
Grammes.	Grammes.
Undressed ... 1400 (3 lb.)	Undressed ... 1400 (3 lb.)
After being peeled they only weighed } 1070 (2·35 lb.)	After being peeled they only weighed } 1050 (2·31 lb.)
Cooked, they weighed } 1050 (2·31 lb.)	Cooked, they weighed } 1030 (2·26 lb.)

The Argenteuil Asparagus when served at table and eaten left a residue of uneatable stalk weighing 400 grammes (0·88 lb.), that is to say, the eatable portion of the 1400 grammes of raw vegetable amounted to close on 1000 grammes or 2·2 lb.

This variety took only twelve minutes to cook, and was tender, sweet, and pleasant to the taste.

The Dutch Asparagus when served at table and eaten left a residue of uneatable stalk weighing 704 grammes (1·54 lb.), that is to say, the eatable part of the 1400 grammes of raw vegetable only amounted to 696 grammes or 1·53 lb.

This variety took seventeen minutes to cook, and was somewhat woody and very bitter.

These results show that there is really no comparison in point of merit between the Argenteuil and Dutch varieties. In point of quantity there is a difference of two-thirds in favour of the former *Asparagus*. Again, in point of price the advantage also rests with the Argenteuil variety, that is to say, 1 franc (about 9½d.) against 30 cents (about 3d.). As for the eatable portion, there is more than one-third more in the Argenteuil variety. Those who grow to sell will have little difficulty in deciding upon which variety to plant. The amateur also who prefers quality to quantity will hesitate still less, as the Argenteuil variety is sweeter and more succulent than the Dutch, which has a disagreeably bitter flavour. To this must be added the fact that the Dutch *Asparagus* requires a richer soil and double the quantity of manure as compared with the Argenteuil variety.

COMPARISON BETWEEN A PLANTATION MADE WITH STOOLS OF A YEAR OLD AND ANOTHER MADE WITH STOOLS OF TWO OR THREE YEARS OLD.

There are still persons who think that if they plant stools of two and three years old they will be able to gather their crops earlier than when employing plants of one year old. In order to disabuse their minds of this old-fashioned prejudice, we shall place before them the result of some comparative experiments which we have recently made in spite of the question having long since been decided. We planted twelve stools of one, two, and three years old respectively in the same soil under the same conditions and at the same time. Calling those plantings Nos. 1, 2, and 3, the following is the result obtained during the first year:—

No. 1.—All the stools came up before May 4 and were well grown.

No. 2.—Ten stools showed above ground before May 4, one on the 10th, and one appeared to be dead. The *Asparagus* heads were very fine—finer, indeed, than those of No. 1.

No. 3.—Eight stools showed above ground before May 4, one on the 12th, and three gave no signs of life. The heads were very fine at first, but they became bent towards the end of the year (September 15) and were much weaker than those of No. 2.

Second Year.—No. 1.—Well-grown, regular, and strong heads, which measured on September 15 1 in. in circumference.

No. 2.—Well-grown, but irregular heads, somewhat weaker than those of No. 1.

No. 3.—Only pretty well-grown heads, very irregular, some of the stools having as many as eight or ten, but all very weak. One stool died after growing two heads.

Third Year.—No. 1.—Magnificent growths, the heads measuring on April 10 from 2 in. to 3½ in. in circumference.

No. 2.—Growth passable only, but very irregular. Some of the stools are very small. The finest of them produced heads which from April 8 to 10 only measured 2½ in. in circumference.

No. 3.—Growth very poor and very irregular. Some of the stools continue to produce small heads not much thicker than a quill pen, the largest being from 1½ in. to 2 in. in circumference.

Fourth Year.—No. 1.—Growth very remarkable. The heads began to show on April 3, 4, 5, 7, and 10. Some are from 3½ in. to 4 in. in circumference, and measure 4¾ in. Fifty of the heads form a bundle which weighed 3200 grammes (7 lb.).

No. 2.—Growth passable, but later than No. 1. The heads made their first appearance on April 6, 10, and 11. Many

of them were very small; fifty of them barely made half a bundle, and only weighed 1700 grammes (3¾ lb.).

No. 3.—Growth but poor, and somewhat late. The heads made their appearance on April 4, 6, 9, and 11; one did not show till the 22nd. Fifty heads barely formed half a bundle, and only weighed 1150 grammes (2½ lb.). To sum up it is clear that the plants of a year old in their fourth season, that is to say, after having been planted out for three years, gave a bundle weighing 3200 grammes (7 lb.), while those of two years old only gave 1700 grammes (3¾ lb.), and those of three years old only 1150 grammes (2½ lb.); in other words, taking round numbers, the plantation made with the one-year-old plants produced double the crop of the two-year-old plants, and treble that of the three-year-old plants. The reader may easily draw his conclusions from the preceding facts.

Sowing in the Open Ground.—Some authors advocate and many persons still adhere to the old-fashioned method of sowing *Asparagus* in the open ground instead of planting out the stools as already directed. This method of cultivation is defective for two reasons: first, because if all the seeds do not come up we must begin our work all over again, which will not only retard the crop of the year and make the plantation irregular; and secondly, every plant, whether good or bad, must be kept in the place where it was sown. Again if two or three seeds come up side by side it is very difficult to thin them out, there generally being two left behind which give rise to a couple of stools, which will certainly interfere with each other's growth, and will only yield a poor and uncertain crop. By adopting the transplantation system we need only use the choicest plants we can get, which is after all the easiest and cheapest way of obtaining fine and profitable crops. The difference between a plantation formed from seed and one made by transplanting the stools is very great, and is so much in favour of the modern system that it can be only ignorance of the results obtained by it that can account for the old-fashioned method being adopted. We have seen even at Argenteuil plantations formed from seed, but with all the care that it is possible to bestow on them they produce exceedingly irregular crops, so much so that they yield less than half the quantity given by the planted beds. The defects of the old system are so apparent that we need not have recourse to any facts in proof of them.

Utility of Earthing up.—We have often been asked to explain the part played by the mounds of earth beneath which the stools are buried at a certain time of the year. Earthing up allows us to plant the *Asparagus* stool less deeply, so that it has all the benefit of the manure, the rains, and the spring sun. It also allows us to shelter the heads from the influence of the atmosphere and the light, so that they do not turn green and hard, but remain white and tender, besides growing much longer. Another advantage gained by earthing up is to prevent all danger from the late spring frosts, the young shoots being so well covered up that they experience no injury. In certain localities people have not yet learned to distinguish the difference between blanched and green, and many affect to prefer the latter. This vulgar error cannot be too quickly extirpated in the interests of all true lovers of this delicious vegetable. In the case of the green *Asparagus* it is only the tip of the shoot that is eatable, whereas the blanched *Asparagus* can be nearly all eaten, besides which it is infinitely superior in point of tenderness and flavour. *Asparagus* which is green at the moment of gathering should only be used as a garnishing for Peas. No one with any pretensions to good taste would serve up green *Asparagus* to table. In the Paris market green *Asparagus* only fetches

1 franc a bundle (9'6d.), while the blanched vegetable fetches 3 francs (2s. 4'8d.). The green Asparagus is never eaten in Paris, but is used for making syrup of Asparagus and other pharmaceutical preparations. GODEFROY LEBŒUF.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 16.

THE chief attractions on this occasion were the superb collections of cut blooms of Dahlias, Asters, &c., exhibited by various contributors. Groups of plants were also shown, amongst which were several of special interest.

First-class Certificates.—These were awarded to the following:—

Cypripedium calanthum (Veitch).—A handsome hybrid variety, the result of a cross between *C. Lowi* and *C. biflorum*, and one which partakes of the character of both parents.

C. cœnanthum (Veitch).—Also a hybrid, raised between *C. Harrisianum* and *C. insigne Maulei*. A fine addition to this type of Lady's Slippers.

Nepenthes Wrigleyana (Veitch).—A variety with handsome pitchers produced plentifully. It is the result of a cross between *N. Hookeri* and *N. phyllamphora*.

Tillandsia Lindenii vera (Williams).—A beautiful Bromeliad with a rosette of narrow curved leaves, from which are produced the flower-stems bearing bright purple blossoms, which appear from the axils of bright pink bracts arranged in two rows on either side of the stem.

Nepenthes robusta (Williams).—A strong-growing kind, with large, well-formed, and elegantly-spotted pitchers.

Ophiopogon Jaburan variegatum (Lloyd).—A prettily variegated-leaved variety of an old plant, which bears numerous spikes of purplish blossoms. The plant, moreover, has an elegant habit of growth.

Verbena Mr. Thompson (Mould).—A beautiful variety, of large size, both in truss and pip. The colour is bright scarlet, with a conspicuous white eye.

Dahlia Ethel Britton (Messrs. Keynes & Co.).—A kind with flowers of large size and fine form, of a creamy-white colour, with the florets tinged with a purplish hue.

Second-class Certificates were awarded to the following:—

Drosera dichotoma rubra (Bull).—This differs from the original in the glandular hairs of the stem being of a reddish colour.

Agave marmorata (Boller).—A variety much in the way of the American *Agave* (*A. americana*), but having the leaves marked with transverse bands of white, which give the plant a pretty appearance.

Dahlia Yuaiczi (Cannell).—A Botanical Certificate was awarded to this; it is a scarlet-flowered variety with the florets arranged so that the head resembles the flower of a *Cereus*.

An attractive and tastefully-arranged group was shown by Messrs. Veitch & Sons, comprising, in addition to those mentioned above, a choice collection of Pitcher Plants, which for the most part were of hybrid origin, such as *Nepenthes Courtii*, a free-growing, dwarf-habited kind, with handsome flask-shaped pitchers of large size. *N. Hookeri elongata*, *N. Chelsoni*, *N. maculata*, *N. Rateliffiana*, *N. zeylanica rubra*, are all uncommon kinds, but all of the highest merit; the pretty *N. Sedeni*, too, is a highly desirable plant, as well as its rarer congeners *N. Stewarti*, *N. Kennedyana*, and *N. Wrigleyana*. The handsome *Sarracenia Chelsoni*, a hybrid between *S. rubra* and *S. purpurea*, is a fine addition to the cool-house Pitcher Plants, and will no doubt meet with much appreciation when it becomes less rare. Other insectivorous plants were shown in a small group, such as *Droseras*, *Darlingtonias*, &c. Numerous Orchids in flower enlivened the group, such as the well-known *Zygopetalum maxillare*, with an abundance of flower-stems; a fine example of *Saccolabium Blumei majus*, the beautiful *Dendrobium bigibbum* and *D. formosum*, *Phalenopsis Esmeralda*, and a superb variety with a broad, amaranth-tinted lip of *Laelia elegans*. Of hybrid Orchids there was a numerous display, particularly of Lady's Slippers. Of these *Cypripedium cœnanthum* and *C. calanthum*, already mentioned, were among the newest. Other interesting kinds were *C. selligerum*, a hybrid between *C. levigatum* and *barbatum*, *C. vexillarium*, with *C. barbatum* and *C. Fairieanum* as its parents,

the pretty and now well-known *C. Sedeni*, *C. Harrisianum*, and others. A fine hybrid *Cattleya* bearing the name of *C. Manglesi* is an acquisition amongst autumn-flowering kinds, and so is *C. hybrida picta*, a cross between *C. guttata* and *C. intermedia*. The rare *Zygopetalum Wendlandi* was amongst the number and is referred to elsewhere in our columns. The beautiful greenhouse hybrid *Rhododendrons* added much to the attractiveness of the group. These included the crimson *Duchess of Edinburgh*, the delicate rosy-pink *Taylori*, *Princess Frederici*, &c. From Mr. Bull came a small group of new plants, including the handsome *Dendrobium Goldiei*, and the more curious than beautiful *D. undulatum fimbriatum*. *Adiantum bellum*, *mundulum*, and *dissectum*, all elegant Maidenhairsts, were also in the group, together with the new *Calyptronomia Swartzii*, an elegant Palm of graceful habit. Four varieties of new *Coleuses* were also shown, of which one named *Sparkler* and another *Butterfly* showed very quaint markings. A small collection of choice plants were also contributed by Mr. Williams; the lovely *Tillandsia Lindenii vera*, alluded to elsewhere, being the admiration of every one. *Dendrobium superbiens*, very similar to *D. Goldiei* in the previously named collection, the beautiful Australian *D. bigibbum*, a fine example of *Odontoglossum Pescatorei*, and a curious kind bearing the provisional name of *O. albo-labium* were amongst the most conspicuous of the Orchids. *Calamus densus* and *Cocos elegantissima*, a very graceful Palm with the pinnae of the leaves arranged in a similar manner as in *C. flexuosa*, but of an elegant, arching habit, were noteworthy plants also. A flower of the lovely pink *Nymphaea Eugénie* also came from the same garden. Mr. Green, gardener to Sir G. Macleay, Pendell Court, Bletchingley, contributed some interesting cut flowers, including fruiting spikes of *Gunnera scabra* and the rarer kind *G. manicata* for comparison; also *Aristolochia Kämpferi* (syn., *A. trilobata*), a singular species with flowers strikingly resembling the pitchers of a *Nepenthes*; *Carolinea insignis*, a noble *Sterculiaceus* plant, the flowers of which are rendered remarkable by the large tassel-like tufts of stamens. The flowers of the lovely *Lagerstromia indica*, a stove shrub not often seen in flower, were also shown by Mr. Green; also flowers of the newly named *Montbretia Pottsi*, though not new to cultivators, as Mr. Green has grown it for years without a definite name. Messrs. F. and A. Smith, Dulwich, sent plants of *Tabernaemontana Camassa*, a *Gardenia*-like plant, though lacking the delicious perfume of the latter; also a mottled-leaved form of *Ficus elastica*, though not at present very distinct. *Ageratum Princess Beatrice*, a dwarf-growing kind, was sent by Mr. Todman, Tooting Common. Mr. Boller contributed a few interesting kinds of Succulents—of which some were new, others rare—such as *Agave Shawi*, *A. Victoria Regina*, *A. albicans*, *A. flagelliformis*, *A. aristata*, &c. Cut blooms of *Marigold Meteor* were sent by Messrs. Haage & Schmidt, Erfurt. It has the florets of a pale yellow tint conspicuously margined with deep orange. A collection of fine seedling *Verbenas* was shown by Mr. Mould, Pewsey, Wilts; and by Mr. Camell, in addition to Dahlias, a fine display of cut blooms of the showy *Tiger flower* (*Tigridia Pavonia grandiflora*); also examples of a choice strain of *Cockscombs*, &c.

A fine collection of Dahlias was shown by Mr. Walker, Thame, Oxon, consisting of about four dozen blooms of the finest sorts. Most of these were represented by blooms measuring as much as 5½ in. across, and of perfect form. Amongst them the most conspicuous were *Earl Radnor*, a fine plum-coloured kind, *Mrs. J. Downie*, white with a delicate flush of purple. *Flora Wyatt*, *Willie Eckford*, *Monarch*, *Ovid*, *Henry Walton*, were also amongst the best. These were deservedly awarded a silver Banksian medal. From Messrs. Keynes & Co., Salisbury, came a similar contribution, consisting chiefly of seedlings. Of these the finest were *Ethel Britton*, to which was awarded a certificate; *Triumphant*, a bright crimson; *Victor*, a deep red; and *Frederick Smith*, an unusually large and fine flower of the fancy type, of a violet tint striped with a darker hue. A fine collection of about thirteen dozen blooms was exhibited by Mr. Cannell, Swanley, comprising many of the show, fancy, and bedding sections, besides a numerous collection of the bouquet kinds, all of which were remarkable alike for the cultural skill which they exemplified. A silver Banksian medal was also awarded to this fine collection. In addition to this Mr. Cannell also showed a collection of the original single flowered kinds such as *D. Cervantesi*, *coccinea*, *glabrata*, and *Paragon*. A beautiful *Cactus-flowered* kind, named *Yuaiczi*, obtained a botanical commendation. The florets are not quilled as in the florists' varieties, but are straight and arranged in a rosette-like manner. The singular green-flowered *Dahlia* (*D. viridiflora*) was also shown in this collection. Mr. Smith, Edmonton, also contributed a dozen blooms of choice varieties, all of large size, excellent form, and diverse in colour. A similar number came from Messrs. Rawlings, Romford, which like all the rest were in capital condition, notwithstanding the past unfavourable weather. Cut blooms of Asters were numerous represented; an excellent collection was exhibited by Mr. Walker. It comprised named varieties of the quilled section, and a large number of other types,

all of which though fine were inferior to those seen here on former occasions, a circumstance doubtless owing to the inclement season. A silver Banksian medal was deservedly awarded to these, and a similar award was voted to Mr. J. M. Gilkes, Wickham, Newbury, also for a collection of Asters consisting chiefly of the quilled type. Asters were also numerous shown from the Society's gardens, those of Benary's strain being particularly fine.

Fruit.—Of this there was but little to engage the attention of the committee. A seedling Melon named Hyde's Hybrid was sent by Mr. Hyde, Farnborough Park. A sample of a white transparent Apple was shown by Mr. Killick, Maidstone, which was considered a good variety, and deserving of more extended knowledge. The same exhibitor also showed a dish of Sutton's Magnum Bonum Potato, as being the only variety out of forty grown that has quite escaped the disease. Sutton's Red Fluke was also shown, of which five per cent only were diseased.

INTERNATIONAL POTATO EXHIBITION.

SEPT. 17—18, 1879.

THIS, the fifth annual exhibition of Potatoes, was held on Wednesday and Thursday last at the Crystal Palace. On the whole there was an excellent display, and though it fell somewhat short in point of numbers compared with that of last year, the quality of the exhibits was in all respects everything that could be desired. They showed a remarkable evenness, the majority being good and none decidedly below the average. The almost entire immunity of the tubers shown from the prevailing disease, which is exceptionally virulent this season, was very noteworthy; only a very small percentage showed traces of it.

In the premier class for twenty-four varieties prizes were given of the value of twenty-four guineas. The best collection was shown by Mr. P. McKinlay, whose lot were characterised by evenness and clean appearance, combined with large size. The varieties included amongst coloured Kidneys—Trophy, Grampian, Late Rose and Early Rose; white Kidneys—Early King, Wiltshire Snowflake, Magnum Bonum, International Kidney, Snowflake, Beckenham Beauty, Woodstock Kidney, Womerleighton's Seedling. Of red Rounds there were Triumph, Manhattan, Blanchard, Beauty of Kent, and the new Vicar of Laleham. White Rounds were represented by Schoolmaster, Shelburne, Climax, and Rector of Woodstock, all excellent in every point. Mr. T. Pickworth was second with excellent dishes of tubers, amongst which the most noteworthy were Triumph, Sutton's Red Skin, Grampian, of red-skinned Rounds; Schoolmaster, Porter's Excelsior, Dalmahoy, Bresee's Peerless, in the white Rounds. Of Kidneys, International, McKinlay's Pride, Woodstock Kidney, were shown well. The third prize was awarded to a northern grower, Mr. W. Kerr, Dumfries, whose collection was excellent, though some dishes were rather undersized. The fourth prize collection also was remarkably good; it was shown by Messrs. Lott & Hart, Faversham. An extra prize was awarded to another Faversham grower, Mr. Akehurst, and Mr. W. Finlay's collection from Banbury was commended for general excellence. The prizes for eighteen distinct varieties, of the value of eighteen guineas, were presented for competition by Messrs. Sutton & Sons, Reading. Sixteen exhibitors contested in this class. The finest collection was staged by Mr. F. Cresswell, Ipswich, who had excellent tubers: of coloured Rounds—Triumph, Grampian, Brownell's Vermont Beauty, and Blanchard; of white Rounds were Norfolk Giant, Alpha, and Porter's Excelsior. Coloured Kidneys were represented by Brownell's Superior, Late Rose, and Lady Webster; white-skinned sorts were Veitch's Improved Ashleaf, International, Snowflake, Woodstock, Oyster, Covent Garden Perfection, and Rector of Woodstock. Mr. J. Matthews, Sittingbourne, showed the next best collection, comprising fine tubers of Snowflake, International, Grampian, Beauty of Hebron, Schoolmaster, Davis's Improved Ashleaf, Blanchard, Magnum Bonum, Lye's Favourite, Scotch Blue, and Early King. The third place was taken by Mr. W. Finlay, Banbury, whose collection on the whole was good, though some of the dishes contained rather undersized tubers. Mr. Crump took the fourth prize, and Mr. Wildsmith the fifth. The next class was for twelve varieties. A fine collection was shown for the first prize by Mr. T. Pickworth, Loughborough, Leicestershire. The kinds were, of coloured Rounds, Triumph, Grampian, Blanchard; white Rounds, Bresee's Peerless, Porter's Excelsior, Lady Gordon, Premier, and Bresee's Prolific. Of Kidneys were King of Flukes, International, and Beauty of Hebron. The second best lot comprised fine examples of Snowflake, Pride of Ontario, Schoolmaster, Woodstock Kidney, and Scotch Blue. There were seventeen exhibitors in this class, and the prizes were given by Messrs. Hadley, Abbiss, and Fawell. A numerous and well-contested competition characterised the class for six dishes of distinct varieties. The first place was taken by a re-

markably good collection consisting of Trophy, Early Vermont, International, Beauty of Hebron, Bresee's Prolific, King of Flukes, all exemplifying high cultural skill. This collection was shown by Mr. T. Pickworth. The next best was also excellent, including Red Emperor, Grampian, as Red Rounds; Schoolmaster, Trophy, International Kidney, and Snowflake, of Kidney kinds. An error in the nomenclature of one variety disqualified the next best collection, and the prize was accordingly awarded to a well-grown lot from Mr. Matthews, who had fine examples of Snowflake, Triumph, and International Kidney. In the fourth collection were Beauty of Kent, Snowflake, Breadfruit, Early Vermont, all of excellent quality. There were two dozen exhibitors in this class, and the first two prizes were given by Messrs. P. McKinlay and Barr & Sugden. The class for four dishes consisting of two Round and two Kidney varieties was well contested, there being twenty exhibitors. The best came from Mr. F. Miller, Northdown, Margate, who had Ashtop and Snowflake for Kidneys, Radstock Beauty and Blanchard for Rounds, all well-grown and even. The next best contained Red Emperor, Blanchard, International, and Myatt's Ashleaf. The third place was taken with fine tubers of Trophy and International, Kidneys; Radstock Beauty, and Schoolmaster, Rounds. For four dishes of distinct new varieties not in commerce, or in commerce for the first time this year, there were seven exhibitors. Mr. P. McKinlay, Penge, headed the list with Beckenham Beauty (a handsome white Kidney), Woodstock Kidney, Vicar of Laleham (a dark-skinned Round kind), and Shelburne (a smooth-skinned Round of medium size). Mr. R. Dean, Ealing, was second with Vicar of Laleham and Early Purple (a purple-skinned Kidney), Cosmopolitan and Avalanche (white Kidney varieties). In the next lot were Woodstock Kidney, Heather Bell, and Tiftie's Annie (a kind very similar in appearance to Blanchard). The other collections included, besides above-mentioned kinds, Johnston's Downshire and Beauty of Kent of coloured Rounds; Washington, Early Bird, and Britannia, Kidneys; Dux and Criterion, white Rounds. In the next class for two dishes consisting of one Round and one Kidney variety, the prizes were given by the Amies Chemical Manure Company. Twenty-three collections were exhibited. The best was shown by Mr. Matthews, who had excellent examples of Porter's Excelsior and International Kidney. The second prize was won by the International and Schoolmaster varieties. The class for any white Round sort brought out twenty-two exhibits. The variety Schoolmaster was awarded the first prize, which was shown by Mr. Kerr; Mr. R. Dean was second with fine tubers of Porter's Excelsior; Woodstock Round was shown well by Mr. Pallister for the third place. Bresee's Peerless, Excelsior, Regent, and Henderson's Prolific were also well represented. The best dish of a coloured round Potato was shown by Mr. R. Dean, who had fine tubers of Lye's Favourite. The sort Blanchard took the next two prizes. There were sixteen dishes exhibited, and Triumph, Grampian, Early Emperor, Red Emperor, were admirably well shown. The best dish of white Kidney variety was shown by Mr. W. Finlay, who had excellent tubers of International. Woodstock Kidney was awarded the second prize, and Beckenham Beauty the third. Twenty-six dishes were exhibited in this class, the variety International being the sort chiefly shown. The best dish of any coloured Kidney kind was shown by Messrs. Lott & Hart, Faversham, who had fine tubers of Trophy. The next was red Kidney shown by Mr. W. Kerr, Dumfries, and Brownell's Superior was shown for the third place. Seventeen dishes were exhibited in this class, the prizes being presented by Mr. J. Crute. Ten dishes were staged of Radstock Beauty for the prizes offered by Mr. R. Dean, Ealing. The best was shown by Mr. F. Miller, Margate, who had clean and handsome tubers. There was a numerous competition for Messrs. Sutton & Sons' prizes offered for their white Kidney Potato Magnum Bonum, which was shown exceedingly well, there being twenty-two dishes shown. The best came from Mr. W. Crump, Blenheim, Woodstock; and Mr. Baldwin and Mr. G. Masters were placed next in the order named.

Miscellaneous Class.—Messrs. Sutton & Sons, Reading, exhibited a large sample of their new Magnum Bonum Potato, and a smaller one of Woodstock Kidney, also a new variety. From Messrs. Harrison & Son, Leicester, came a large assortment of tubers comprising about three dozen varieties.

A collection of Gladioli, consisting of about 250 spikes in sixty varieties, was sent by Messrs. Vilmorin-Andrieux & Co., Paris, which considerably enlivened the surroundings. Mr. Cannell, Swanley, also contributed cut blooms of Dahlias, Tigridias, Verbenas, &c., and Mr. Boller showed an interesting collection of Cacti, &c.

A list of awards will be found in our advertising columns.

Webb's Improved Banbury Onion.—This is one of the handsomest of all Onions. It forms bulbs quickly, and has a wonderful tendency to remain small in the neck. It keeps very well, and is altogether a most useful variety.—T.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

THE autumn show of this Society took place the other day in the Waverley Market Hall, Edinburgh, and despite the unfavourable climatic influences with which horticulturists have been and are still contending, the show was in every respect a success. The Lawson Seed and Nursery Company greatly enhanced the general appearance of the hall. Instead of displaying their plants and flowers on the orthodox staging, the company had laid out the part of the hall allotted to them—nearly a quarter of an acre—as a flower garden, and grouped their exhibits into tasteful figures with the best effect. At the extreme west of the hall was a fine clump of variegated Coniferae, prettily graduated with a wavy border of Golden Box; in the centre was a large oval flanked by circles, while to the east was another crescent-shaped parterre. In these, tree Ferns, Palms, Crotons, Dracaenas, Coniferae, and florists' flowers were arranged with perfect taste; and this flower garden fairly divided with the fruit display the honours of the day. The idea so commended itself to all who saw it that it is not unlikely to supersede the staging, at least for nurserymen, on other occasions. There is usually a good display of fruit at the autumn show; but on this occasion it far exceeded anything that has been seen before in Edinburgh, except at the International Exhibition. Of Grapes especially there was a splendid display—there being close upon 300 bunches on the tables, and nearly all of excellent quality. Mr. Dickson showed a bunch of Syrian weighing 13 lb. 3 oz.—a figure which, however, does not approach to some of the former prize bunches in the same competition. The best flavoured Grape was declared to be the Duchess of Buccleuch.

PLANT ARRANGEMENT AT FLOWER SHOWS.

I THINK it would be much better if the custom of erecting stages at flower shows could be entirely abolished. When, as is often the case, the plants are placed upon platforms of a more or less elevated description, not only is there a difficulty in concealing the pots, but the specimens themselves show to much less advantage than when placed upon the level ground. The graceful proportions of a Fern or a Palm, or the merits of a well-grown, finely-bloomed Erica or Fuchsia, can be best judged when the whole plant comes well below the level of the eye. This remark will also apply not only to the single specimens but also to the group or series of groups of which the exhibition may be composed. At the recent exhibition of the Byfleet Horticultural Association, the whole of the plants were disposed upon the Grass, an arrangement which produced a very pleasing effect and which elicited warm expressions of approval from the visitors. The plants were disposed in semi-circular groups against the canvas, thus affording a very pleasing *coup d'œil* from the entrance to the tent. Another feature of this exhibition to which I would wish to direct attention is that, instead of forming classes containing a fixed number of plants, the exhibits consisted exclusively of groups, in which the competitors were restricted only to space. By varying the space to be covered, little growers were enabled to compete on advantageous terms, and more groups were formed than could otherwise have been the case. When the show is of a purely local character, and the neighbourhood not a large one, it would be wiser to follow some such system as this than to restrict exhibitors to a certain number of specimens, as it often happens that either the grower cannot muster the required number or that he hesitates to bring forward a somewhat uneven lot. Many small growers are thus debarred from exhibiting, and many a good plant in this way remains at home instead of gracing the exhibition tent. Another point in favour of the grouping system is that it affords scope for the exercise of taste in the grower, who may often, with plants of an ordinary description and of not large dimensions, form groups of a pleasing description. Illustrations of this were to be seen in groups of fine foliaged and flowering plants arranged by Mr. Rose and Mr. Parker, which, although not containing anything very rare or costly, yet, owing to judicious and tasteful arrangement, produced an exceedingly pleasing impression. The gardener is now more than ever called upon to cultivate both judgment in selection and taste in arrangement; he must not only know how to grow his plants well, but the knowledge of how to place them to the best advantage is often required of him. This, therefore, being such an important affair, should not be lost sight of at plant exhibitions, and no form of exhibiting can so well call forth the energies and resources of the grower in this respect as the arrangement of groups of flowering and foliaged plants, limiting him to space, but allowing of the full exercise of judgment in the choice of subjects. Let me, however, not be misunderstood. I would not wish to confine a show entirely to groups. When the neighbourhood is large enough, by all means form classes, in which the capabilities and merits of certain plants or classes of plants may be displayed in the so-called speci-

men stall. In the case, however, of the exhibition already mentioned, which was very successful, I am convinced that only by the method described could a flower show have been formed. I also feel certain that there are few neighbourhoods in which an exhibition of plants might not be organised were the group system entirely relied on.

JOHN CORNHILL.

ANSWERS TO CORRESPONDENTS.

Permanent Hedge.—In answer to "François" (p. 252) I can say that in November of 1877 I planted about 250 ft. of boundary with the Myrobellia or Cherry Plum, sent out by Mr. Ewing for this purpose. It is now a thick, close hedge about 4 ft. high, with a good bottom. In another twelve months I expect it will be practically impenetrable. It is planted on the flat close up to the posts and rails.—C. H. G., *Staines*.

—Having already a wood fence that ought to be able to offer the required protection for a few years, "François" will find that the best possible kind of permanent plant fence will be one made with Holly. As a stout, firm, dense, and indeed almost impenetrable fence plant the Holly is unrivalled, but it needs time and patience to bring it to a good hedge condition. Unlike Quicksets—the commonest and perhaps the cheapest material—Holly is evergreen; it does not require to be so thickly planted, and needs much less looking after. It is, perhaps, somewhat more costly to start with, but as to its advantages when the hedge is established there can be no question. Good plants from 15 in. to 20 in. in height, well rooted, planted in a single line at from 15 in. to 15 in. apart, need only to be kept clear and growing upward, the sides being kept in place by means of a knife or shears. Such a fence will need neither bank nor ditch, as when from 5 ft. to 6 ft. in height, and 2 ft. through, it would almost repel an army.—A.

Hardy Flowers for Beds.—I have a bed partly filled with Tritomas, White Japan Anemone, Rudbeckia Newmanii, and Sedum spectabile; what other autumn-flowering perennials would harmonise with these?—Q. [Plant the red Japan Anemone; also two or three of the perennial Asters or Michaelmas Daisies, which should have positions in the bed according to their respective heights. Physostegia imbricata is also a fine autumn plant, bearing as it does spikes of flowers of a soft pink hue, resembling those of a large Epacris. It likes a deep soil, and makes a growth of some 4 ft. in height. Pentstemons, especially those from spring sowings, flower finely late in autumn, as do also Antirrhinums. Beds of these from spring seedlings are very brilliant in colour. Good autumn flowers that will fill up the interval between the bedding plants and the incoming of the Chrysanthemums are most valuable, and if not all perennials should not on that account be rejected. Some good patches of the Colchicums would not be out of place in such a bed, or any of the autumnal flowering varieties of the Crocus.—D. E.]

Climbers for Trellis Work.—I have just had about 40 ft. of trellis work erected to divide my flower and kitchen gardens, and as one side faces the house I wish to cover it with hardy flowering climbers. Would you kindly inform me if Passiflora corneola and Clematis will succeed on it, or what other climbers would do well? The open side of the trellis faces the south-east.—P. [Passiflora corneola and all the hardiest kinds of Clematis should do well on the trellis described; also some hardy Vines, especially the Ciotot or Parsley-leaved kind, which is very ornamental, and the Madresfield Court, which assumes such glorious tints in autumn. Jasminum nudiflorum, Forsythia viridissima, Cotoneasters, variegated Ixias, the Lawton and other American Blackberries, the Wistaria sinense, Virginia Creeper, good hardy climbing Roses—these alone would furnish the fence and do well. Evergreen climbers should do well interspersed with the deciduous kinds, or those that lose their foliage in the autumn. Vines look well trained up at intervals to resemble piers, and their shoots trained along the top make a framework for the other plants. Such plants as Tropaeolums, Echemocarpus, Cobea scandens, &c., sown or planted in the spring would help to give brightness and colour during the summer.—A. D.]

Names of Plants.—*Woodville*.—The Truffle-like fungus is Scleroderma vulgare, a very disagreeable (if not dangerous) species, and best avoided. *B. H.*—The flower sent had shed its petals before it reached us; apparently it is *Pteronia elegans*, but we cannot accurately determine without leaves. That to which you allude is probably *Lasiandra macrantha*, also a handsome *Melastomad.* *M. J. F.*—*Clarkia pulchella*. *A. P.*—*Ceanothus Arnoldii*. *G. S.*—1, Double-flowering Bramble; 2, *Helenium autumnale*; 3, *Sedum spectabile*. *J. E.*—*Bromus secalinus*. *C. C.*—3, *Heermannia natalensis*; 1 and 2, next week. *T. H. A. H.*—*Achillea Ptarmica*, *Pteris tricolor*. *G.*—1 and 3, send when in flower; 2, *Santolina incana*. *S. S.*—*Bartonia aurea*. *Woodville*.—The small shrub is the Whortleberry (*Vaccinium Myrtillus*); the other was withered beyond recognition. *H. C.*—*Zygopetalum Mackayi*. *Enquirer*.—The leaf sent is probably from an *Ampelopsis*, but we cannot tell from such scanty material. *F. F.*—*Epidendrum cochlearatum*. *C. J. N.*—*Diplopappus fruticosus*. *J. S. T.*—1, *Coreopsis lanceolata*; 2, *Monarda didyma*; 3, *Lavatera trimestris*; 4, *Echinops ruthenicus*. *Deroa*.—We cannot undertake to name florists' flowers, as it cannot be done accurately, except by specialists.

OBITUARY.

It is with deep regret we have to record the death of Mr. William Wilson Saunders, F.R.S., an event which took place at his residence, at Raystead, near Worthing, on the 13th inst., at the age of 70. The eminent services which Mr. Saunders has rendered to botany, entomology, and kindred sciences are universally acknowledged. To horticulture, also, he was specially devoted, and his garden at Hillfield, near Reigate, was remarkable for the great variety of interesting plants which it contained. He took great interest in the Royal Horticultural Society, of which he was a Life Member. Kind in disposition and upright in all his dealings, his loss will be severely felt, and by none more, we feel sure, than by the readers of THE GARDEN, to which he was a constant contributor.

We have also to announce the decease of Mr. Davis, for forty years gardener to Viscount Bridport at Cricket St. Thomas, Chard, Somersetshire. His death was the result of an accident.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NOTES OF THE WEEK.

The White Lapageria.—(*L. alba*).—Of this we have received a magnificent example from Mr. Titus Salt's garden at Milner Field, Bingley, Yorkshire. It consists of a shoot 6 ft. long, into 3 ft. of the middle of which were crowded forty-eight fully expanded flowers, in clusters of from three to four each. Of unexpanded buds there are eighteen on the same shoot towards the top, making altogether a wreath of pearly bloom such as we have never before seen. Mr. Anderson the gardener at Milner Field, states that in the house devoted to Lapagerias, from which the specimen sent was cut, there has been from 1300 to 1500 flowers expanded at one time. The shoot in question was the strongest of three growths on a young plant. Such examples show in a marked degree what can be done with this, one of the most beautiful of greenhouse climbers, by means of skilful treatment.

Anthurium Lindigi.—With the exception of *A. Scherzerianum* Anthuriums are not generally grown for the beauty of their inflorescence; but *A. Lindigi* is certainly deserving of attention, as it has an ovate, shell-shaped flower-spathe 3 in. long, of waxy texture, and pure white, whilst the spadix is of a bluish-purple. The leaves, moreover, are very handsome, being 1 ft. or more long, heart-shaped, and leathery in texture, and of a deep green hue. Like all the species of *Anthurium*, it inhabits the tropical parts of South America; hence in cultivation it requires a stove temperature. It is now in full beauty in the Aroid house at Kew.

The Closed Gentian (*Gentiana Andrewsii*).—One of the handsomest as well as one of the rarest of the cultivated Gentians, is this singular species, which is now in full beauty on the rockery in Mr. G. F. Wilson's garden at Heatherbank. It grows from 1 ft. to 1½ ft. high, and has broad, lance-shaped leaves arranged in opposite pairs at intervals on the stem. From the axils of the leaves on the upper half of the stem the flowers are produced in clusters of from four to six, and frequently as many as from fifteen to eighteen flowers terminate the stems. The flowers are about 1 in. long, and form a club-shaped tube with very short lobes, so that the flower never fully expands; hence it is called the Closed Gentian. The colour is a deep amethystine-blue on the outside, the teeth of the corolla being white, as are also lines running down the inside of the tube. It inhabits damp woods in the North-eastern United States and Canada, where it flowers during August and September. Though it has been introduced into cultivation for more than a century, it is still rarely met with in collections. It is of easy culture, and requires to be grown in a rich loamy soil in a damp but well-drained border.

A Noble Hardy Exotic Shrub.—We have published notes as to the hardiness, or probable hardiness, of *Leptospermum lanigerum*, a large Australian bush with small flowers like those of a white Saxifrage, and we now have great pleasure in recording that there is a very remarkable specimen of it on the lawn at Penrhos, near Holyhead. It is about 18 ft. in diameter of its spread of branches, and 13 ft. high, perfectly well furnished and healthy, the smallest leaves of a greyish hue, covered with flowers somewhat like those of *Saxifraga Burseriana*, it may be imagined how beautiful it must be and how distinct. The district is much exposed to the sea breezes and even the hardiest trees are shorn by the winds, but it occupies a sheltered place on the lawn. After surviving here in perfect health the past winter and spring, no one can doubt that this shrub (an illustration of which is given in another page) will prove equally hardy over large districts of the country, certainly in all sea-shore and mild ones.

Brassavola Digbyana.—This little known West Indian Orchid is one of the few which have the lips of the flowers beautifully margined with a long and elegant fringe. The flowers, which measure nearly 8 in. across, are of a greenish-white colour, slightly tinged with purple. The lip is white, and has an emerald-green centre, 3½ in. in diameter, and the fringe varies from 1 in. to 1½ in. in length. In habit this *Brassavola* somewhat resembles a *Cattleya*, being about 1 ft. high, with leaves of a pale green, overlaid with a glaucous hue. It is now in flower in the Pine-apple Nursery, Maida Vale, where it forms an attractive object. It has been successfully imported in quantity from Honduras by Messrs. Henderson.

The Herbaceous Ground at Kew.—Visitors to the hardy plant collections at Kew will find that an alteration has recently been effected with regard to the arrangement of the bulbous

plants. Owing to the rapid and continued increase in the numbers of these it has been found necessary to remove the Liliacæ from the head of the ground to the borders outside the wall which skirts the main portion. By this arrangement all the sections of the Order are in close proximity to each other and not separated by other families as hitherto. All the permanent Iridacæ will be placed on the opposite side of the wall, and the Amaryllidacæ will be located on the slip of ground which encircles the *Gunnera scabra*. This alteration will considerably facilitate the finding out any particular genus, a task which a stranger has often found tedious.

The Rock Abelia (*A. rupestris*).—This pretty Japanese shrub at present forms one of the most attractive objects on the "rookery" in Mr. G. F. Wilson's garden at Heatherbank, Weybridge, where it has been for several years quite unhurt by the severe cold of our winters. Its neat habit of growth, glossy green leaves, and abundance of delicate mauve trumpet-shaped blossoms—which, moreover, emit a pleasant fragrance—commend it to the notice of everyone. Though perfectly hardy in such a position in Mr. Wilson's garden, it however, requires the protection of a wall in low-lying districts, as, for instance, at Kew, where the plants against the walls are now finely in bloom. It was introduced to this country by Mr. Fortune many years ago.

Disa macrantha.—This splendid species is now in bloom in the Royal Botanic Gardens at Glasnevin, and, so far as my own knowledge goes, for the first time in Ireland. It flowered with Mr. Elwes, of Cirencester, a month or two ago, but does not appear to have received the attention as to publicity which the fact deserved. The flowers are as large or larger than those of *D. grandiflora*, and more rosy in colour. There is a sketch of this plant in the herbarium at Kew, where it forms one of a series of drawings sent by Mr. Sanderson from the Cape eight or ten years ago. Mr. F. W. Moore may be congratulated as the possessor of such a fine plant.—B.

Erica ramulosa.—This very handsome and free-flowering Heath is perhaps the most useful shrub now in flower in the open air, such quantities of pretty bloom does it yield. We noticed fine old shrubs of it at Penrhyn Castle, and also at the College Gardens at Dublin, where it is in various stages. When old it often assumes a broken and picturesque form, attaining a height of from 6 ft. to 8 ft. while young or cut-in specimens are compact in habit. It flowers in succession and apparently equally freely in old or young plants. Every garden should possess plants of it in various stages and positions.

The Giant Fennels in Autumn.—We have recently noticed *Ferula tingitana* in fruit, about 14 ft. high, in the gardens at Brown's Hill, Carlow, the foliage being at mid-September still fresh. In our many attempts to call the attention of lovers of fine hardy plants to the *Ferulas*, we fear we apologised overmuch for their supposed tendency to wither in early autumn, and advised their being placed alone near the margin of a shrubbery, so that no too early blanks would occur owing to their disappearance. The wet late season has no doubt preserved them longer than usual this year. The peculiar merit of these plants is, however, their rare verdure in early spring, where their great soft plumes appear as early as the snowdrops.

Nerine Fothergilli major.—One of the brightest ornaments in the houses at the Pine-apple Nursery just now is this fine bulbous plant, which, like a host of other beautiful Cape bulbs, is grown there largely. It is by no means a novelty, though it is apparently not nearly so well known as it should be, as it is seldom that we meet with it in private gardens. It is usually grown under pot culture, but it attains a larger size when planted in a border in a cool house, and under this mode of treatment it is grown well in Mr. Joad's garden at Wimbledon, who has it in a house devoted to similar half-hardy subjects. Nothing can well exceed the rich crimson colour of the large umbels of flowers, which are freely produced, and few autumn-flowering plants are better adapted for cutting, a state in which they last a considerable time in perfection.

Jasminum azoricum Planted Out.—Tender Jasmines grown in pots are so often failures that the only remedy seems to be planting out in beds or borders, for those who desire many flowers from these plants. A plant of the Azorean Jasmine planted out in a greenhouse at Belmont, Carlow, is now blooming as freely as ever the common Jasmine does in the open air. It is a beautiful plant for cutting for the house, and grown thus, affords abundant blossom for cutting. The odour is delicious. It forms a good rafter, roof, or pillar plant. Mr. Burbidge informs us that he has noticed it in other gardens about Dublin, doing remarkably well planted out. We noticed another very free flowering Jasmine in the gardens at Bodorgan, Anglesea, planted out in an intermediate house, of the name of which we are not certain. It is much smaller in blossom than *J. azoricum*, of a creamy white, and nearly covered with a spray of delicately-scented blossoms.

Darlingtonia californica.—This is becoming a really wonderful plant at Glasnevin, where the pitchers are bolder and larger than we have seen them in the native country of the plant.

Selaginella Kraussiana Naturalised.—This well-known little hothouse Moss is freely naturalised among the native Mosses in the grove round the lawn at Penrhos. On the lawn the delicate little Ivy Hairbell (*Campanula hederacea*) is abundant.

Dracæna indivisa at Penrhos.—Large specimens of this have stood the winter without injury in the gardens at Penrhos, Anglesea. In a winter when so many plants have perished it is satisfactory to know that this fine-leaved one has survived. The district is exposed, but the spot where the tall specimens are is well sheltered by trees.

Osmanthus ilicifolius.—This shrub, which we noticed some time ago as doing so well at Mr. Geo. Paul's nursery at High Beech, is no less remarkable at Bodorgan, in Anglesea, where both the green and variegated forms are now wide spreading shrubs 10 ft. high. As to their hardiness there can be little doubt after the past winter.

Stigmaphyllon ciliatum.—This singularly beautiful stove climber, with yellow blossoms, looking at a distance like *Oncidium* flowers, and having one of the most graceful forms of leaf among all climbing plants, is now in good bloom in an intermediate house at Penrhos. It is a valuable pillar plant. If such climbers were more frequently seen well grown, hothouses might be embellished by their aid alone, and not so often stiff and bare.

Glades of Hardy Ferns at Penrhyn Castle.—Mr. Speed has formed some very charming glades of Ferns at Penrhyn Castle by planting hardy kinds in quantity near the drives, as much in the open sunny places as under trees; much of the surface now covered in this way was once regularly mown, so that in adding a pleasing feature to the place, a considerable waste of labour has at the same time been put a stop to.

Hedychium coronarium Out-of-doors.—A vigorous plant of this beautiful Scitaminad is now in flower in Mr. G. F. Wilson's "wild garden" at Wisley. Its bold, handsome foliage contrasts finely with its lovely white blossoms, and being quite unlike the surrounding vegetation, it has a special interest. In such sheltered places this, and many similar plants, would thrive admirably, and with care would be able to pass through our winters unscathed.

Disa grandiflora var. psittacina.—This remarkably distinct variety of the beautiful large-flowered *Disa* is now in flower in Mr. Williams' nursery, Holloway. Its blossoms are about the same size as those of the type, but the upper, hood-like portion of the flower is of an orange-yellow colour, and more distinctly veined. The sepals are green at the base and also at the tips; the intervening space is of an orange-red hue, altogether affording a striking contrast of colour, and aptly suggesting its varietal name—the Parrot *Disa*.

Seedling Antirrhinums.—Mr. Caudwell, of Wantage, has sent us samples of a fine strain of these popular hardy flowers. They are large both in spike and flower, and exhibit a great diversity of colour, varying from dark crimson with pure white throats to white and yellow selfs. Some, too, are copiously spotted, whilst others are quaintly streaked and flaked with various colours.

Purple Hemp Agrimony (*Eupatorium purpureum*).—Few more desirable plants could be selected for naturalising in moist places than this noble North American Composite. When strongly developed it attains a height of from 6 ft. to 8 ft., and has stout purple stems, and very dark green leaves arranged in whorls of from three to six. The flower-heads are purplish, arranged in broad flat clusters of from 9 in. to 1 ft. across, and are produced towards the end of summer. It thrives best in damp places in stiff soil. The unusually fine specimens of it in Mr. Steven's collection at Byfleet admirably exemplify its adaptability for border decoration as well as for the rougher parts of a garden.

China Asters.—We have received from Messrs. Webb & Sons, Stourbridge, a fine assortment of blooms of these showy autumn flowers as grown at their extensive seed farms at Kinver Hill. Considering they have been grown out-of-doors in such an unfavourable season as the present, we think them remarkably good; most of the blooms measure as much as 3½ in. across.

St. Paul's Churchyard.—The recent improvements connected with the space immediately surrounding St. Paul's Cathedral are now nearly completed at a cost of £5000. The place was opened to the public on Monday last by the civic authorities. The borders are planted with trees and shrubs which will endure a town atmosphere, such as Hollies, Yews, Rhododendrons, Planes, Maples, &c. A few hardy herbaceous plants are interspersed in the shrubberies, and the Michaelmas Daisies are now beginning to be attractive. The

turf is at present as green as it is far in the country. The comparatively small space is apparently made the most of by a skilful arrangement of gracefully winding paths and undulating beds.

Pelargonium Society.—A meeting of this Society was held at Chiswick, on Tuesday last, for the appointment of officers for the ensuing year. The future arrangements of the Society, including some proposed alterations of rules and of the schedule, were discussed. Judging from the balance sheet of the past year, it appears that the Society is in a prosperous condition, there being nearly £80 in the treasurer's hands.

Seedling Roses at Lyons.—The Roses shown at the late exhibition here were not so numerous as usual and contrary to the general rule, the blooms, and particularly the Teas, Bengals, and Noisettes, were not so fine as they ought to be in our favourable climate at this season of the year; while in June and July the hybrid perpetuals were all that could be desired. Some new seedlings were exhibited, but of their merits I cannot conscientiously inform your readers because in my opinion cut flowers do not convey a fair idea of the value of a new variety, as much of course depends upon its growth, foliage, and its more or less free blooming properties, hardiness, &c., unless at first sight it shows something very distinct, either in shape, size, colour, or scent. Nevertheless there was one with which I think proper to make your readers acquainted. Being struck by the large truss of blooms exhibited I made up my mind to learn more regarding the plant. I therefore went to the raiser, Madame Veuve Rambaux, where I found a great number of plants of it covered with blooms, and on nearly all the branches numerous clusters of flower buds. They had been continually in bloom the whole season; it is a seedling from *Rosa polyantha*. The plant, which is dwarf (being about 1½ ft. high), is vigorous, and what is very remarkable, some of the trusses rise about 1 ft. above the foliage and consist of a considerable quantity of blooms both open and in the bud state; on one I counted sixty-five, a number as far as I know very uncommon. The flowers are pure white and last very long in perfection; they measure about 1½ in. in diameter, are very double, and shaped like Paquette (of Gillot fils), also a seedling from *Rosa polyantha*. Each truss will make in itself a splendid bouquet. It will doubtless make a fine pot Rose, and as such will be useful for table decoration if forced to bloom in the early part of the year.—JEAN SISLEY, *Montplaisir, Lyons*.

Botanic Garden, Graz (Styria).—When visiting this garden a few weeks ago, I was struck with the masses of hardy perennials which are cultivated in it; but there are very few houses in which to grow tropical plants. The principal features of the garden, therefore, are collections of trees, shrubs, and hardy herbaceous plants, and last, but not least, Alpine plants; the latter in great luxuriance on a rockery in a shady situation. Amongst Grasses I noticed the very ornamental *Sorghum halepense*, with red flower spikes 5 ft. high; and *S. vulgare*, nearly the same height, but with green flowering spikes. Of Panicums, of which different kinds are grown here, the most attractive was *P. capillare*, the spikes of which are 1 ft. high, and are furnished with minute flowers, making them well adapted for vases or any kind of room decoration during winter. As regards herbaceous plants, the most attractive at the time of my visit were the various species of *Eupatorium* then in full bloom, viz., *E. maculatum*, *E. altissimum*, and *E. purpureum*; the last measured from 6 ft. to 8 ft. in height—a fact which proves that where they have plenty of space in which to develop themselves freely, the growths which they make are all that can be desired. *Sida Napæa* is an herbaceous perennial closely allied to *Hibiscus* in the form of the leaves. Its flowers, which are white, are rather small, but they are produced in great masses. I consider it to be a good plant for any place in which tall-growing plants are required, several shoots being over 8 ft. in height. *Erythrina laurifolia*, with stems nearly 10 ft. high, was in full bloom. *Shepherdia canadensis*, a shrub closely allied to *Eleagnus*, but with larger whitish leaves and brown stem, deserves to be planted more generally in gardens than it is. Perhaps the most beautiful amongst deciduous shrubs was a specimen of *Vitex Agnus castus*, which measured about 8 ft. through, and was bearing one mass of blue flowers arranged in plume-like panicles. Its scented leaves, combined with an elegant habit and pleasing flowers, made this shrub very attractive, especially as it flowers in the end of the summer, a time when most of the deciduous shrubs have ceased flowering. *Sambucus nigra laciniata* proves to be a very handsome shrub, the shape of the leaves being very peculiar and the growth restricted, which is generally not the case with other Elders, which soon outgrow their positions. On the rockery I observed two species of Creeping Juniper labelled *J. nana* and *J. Sabina nana*, neither of them higher than 6 in. Their glaucous hue made them very attractive, covering, as they did, a space of several square feet.—LOUIS KROPATSCHEK, *Laxenburg*.

THE FRUIT GARDEN.

PECULIARITIES OF DIFFERENT GRAPES.

A STUDY of the peculiarities of some of the Grapes under cultivation, and which are found rather difficult to grow, would often, no doubt, promote greater success in their culture than is at present experienced. The Golden Champion, for example, is one of the best-abused Grapes in existence, though no one denies its good qualities as regards size of bunch and berry and flavour, when it does well; but it has often occurred to me that if it could be grown by itself and subjected to special treatment where required, it would turn out different from what it does in a general way. Cracking and blemishes are its great fault, the skin being very tender and susceptible of injury from any cause. The Vine itself is a rampant grower. Had we the convenience we should certainly make the experiment of devoting a house to it and treating it by itself. At present it grows in a Vinery, in a mixed collection, which is forced tolerably early, and sometimes the crop has to be pushed, which does not suit the Champion. The more it is forced the tenderer it becomes, and if hard forcing is prolonged beyond a certain period, cracking and spotting can hardly be avoided. At times, when we have been able to keep the house quite dry and airy from the time the fruit began to change, the difference in the berries has been quite perceptible; decay has been arrested, and they coloured beautifully. The Golden Champion is a Grape which, I think, does best when ripened in July or August, but it must not be hurried, and it should at all times have a dry, balmy atmosphere and plenty of air. It is a Grape, I should think, that would do well in the open air under favourable circumstances. Another peculiarity of this Vine is its unproductiveness when trained on the spur system and closely pruned. It bears best on the young wood. What applies to the Champion applies also to the Duke of Buccleuch, but the latter is not so apt to crack and blemish, at least with us.

This season we have, for the first time, had some fine and well-finished bunches of Venn's Muscat. Hitherto it has presented all the faults of the Muscat Hamburg, and produced a large proportion of stoneless berries; but this season they have set evenly and finished well, and the bunches have been of a good size. With the exception of a very slight difference in the leaves, this Grape is just the same as the Muscat Hamburg, and is a vigorous grower.

A contrast to Venn's Muscat is Pearson's Golden Queen, which is one of the most unflinching croppers I have ever known. This Vine is also a very vigorous and certain grower, and is likely to become a favourite as a cropper, particularly for market purposes. The bunches are handsome in shape, always show in abundance, and never fail to set evenly, and finish and keep well. In colour and flavour, however, it is second-rate. The berries acquire a yellowish tinge, but the colour is not clear like that of the Muscat of Alexandria. Where a profitable crop, is however, desired, it is a Vine to plant. We have taken from a young Vine here, 10 ft. long exactly, over 17 lb. of fruit this season, which is at the rate of about 36 lb. to the 20 ft. rafter, or 72 lb. to each 4 ft. light, as we grow the rods 2 ft. asunder, and the Vine shows not the least signs of distress in any way. The leading cane is very strong, the leaves large and thick, and the side shoots above the average strength. I have little doubt that it would have borne at least twice as much again without injury. Last year it bore a proportionately heavy crop on a 6 ft. rod. The Vine showed more than twice the above number of bunches.

A grand Grape, when it finishes well, is the Madesfield Court, and a fine exhibition variety but for its liability to crack, in which respect it is, however, very erratic. Two Vines here, propagated from the same source, behave quite differently. One, growing in the middle of the Lady Downes's house, produces good-sized bunches and berries, not much less than Muscats, that rarely or never crack; the other Vine, at the end of the same house, where it gets most sunlight and heat, always shows the greatest quantity of bunches, which are not so large as in the other case, nor the berries either, but they colour better, being generally fairly well finished in that respect, and well flavoured, but they always crack more or less. And this has been going on now for nine years. The cracking or bursting of the berries has been over and over again attributed to distension caused by an over-supply of sap, by some cultivators who have had to contend with the evil, and some have professed to stop the bursting by cutting the shoots half-through below the bunch; but that has not had the slightest effect in our case. The berries do not burst on the most vigorous Vine, but on the weak one. My impression is that cracking, both in this and other Grapes that manifest the same tendency, is due to the atmospherical or external causes as much as anything else. The Chasselas Musqué Grape is a bad cracker as most cultivators know; but even although the berry may be rent from one side to the other, it does not prevent the skin from giving way in other places, as might be expected if destitution

from within was the cause. In all cases slow growth and moderate and dry temperatures seem to be better preventives than anything else.

This brings me to the subject of the time of ripening of different varieties; for in mixed Vineries great success is not likely to attend the cultivator unless the varieties to be grown together are assorted with judgment. It is quite common, but not so much now as formerly, to see the Muscat of Alexandria and Black Hamburg grown in the same house; but they are an ill-assorted pair, and one or the other is likely to suffer by the companionship. In skillful hands both may, of course, be grown side by side, but few good Grape growers attempt to do so if they can help it. When it is considered that the Muscat takes nearly two months longer to ripen than the Hamburg, even in a much higher mean temperature, it must be obvious that they cannot both succeed well under the same treatment. If the temperature is kept up and prolonged to ripen the Muscats, the Hamburg's soon shrivel, and both wood and foliage suffer; whereas, if the house be kept cool after the Hamburgs are ripe, the Muscats remain green, and often shrivel prematurely. And what applies to these two varieties applies also to other sorts that differ widely in the same way. The Black Hamburg, Black Prince, Buckland Sweetwater, Royal Muscadine, Golden Champion, Duke of Buccleuch, Muscat Hamburg, Madesfield Court, Foster's Seedling, Grizzly Frontignan, Pearson's Golden Queen, and West's St. Peter's are all sorts that will succeed tolerably well together, although there is as much as a month or more of difference between some of the sorts, if not six weeks. It would be much better to separate those named into two groups, however, in which case we should place Golden Champion, Duke of Buccleuch, Golden Queen, West's St. Peter's, and Madesfield Court together in a later house, and treat the others as the earliest. This arrangement is the best, even if it should necessitate small divisions. Of the last-named varieties, West's St. Peter's, a fine old Grape and good keeper, is the latest; Golden Queen next. The other three come in about the same time, and succeed the Black Hamburg.

Barbarossa, Syrian, and Raisin de Calabre, and, indeed, all the latest Grapes, succeed well along with the Muscat of Alexandria; but the first three require, if anything, more heat than the Muscat to ripen them perfectly, and should have the warmest end of the house. Lady Downes and Black Alicante will ripen and do well in the Muscat house also, but they require less heat than the latter, and do better by themselves, or in the coldest end of the house. There can be no doubt that the arrangement of the different varieties of Grapes into groups that grow and ripen and keep well together is by far the best and most economical plan, and it should always be carried out where practicable.

J. S. W.

PEACH TRELLISES AND BORDERS.

THERE are two ways of training Peaches under glass in this country. One—a common way—is to train the trees planted in front to a short trellis, perhaps from 6 ft. to 8 ft. or 10 ft. high, according to circumstances, and those on the back to the wall, which is usually occupied by "riders." The object of shortening the front trellis is to admit light to the back trees, and this arrangement is contrived in the conviction that more space is obtained, and consequently more fruit. That a little more space may be obtained when the front trellis is depressed away from the glass, as well as shortened, I do not doubt, but that the crops are more plentiful in consequence I do not believe; and in that conviction I have done away with all our back trellises in both early and late Peach houses, and now train the trees up under the roof, about 1 ft. from the glass, right from the base line in front to the top of the back wall, and we have much better crops than were gathered by the old plan. The space obtained is a little less, but that is more than compensated for by the position which the trees occupy, being nearer the glass, and as regards ventilation, on the back wall the bottom portions of the trees would be from 7 ft. to 10 ft. from the glass, and an experienced cultivator knows what that means in the case of plants grown under glass for any purpose. I have invariably noticed that front trees, when confined to a short front trellis, such as has been described, make a thicket of growth annually at the top of the trellis, which has of course to be cut entirely away as fast as it grows, thus destroying the energies of the trees and their fruitfulness. And it is the same on back walls where the standards have just about the same amount of head room. How much better, then, would it be to let the trees grow and have fewer of them, of good size and development, instead of a number of dwarfed specimens that can only be kept within bounds by mutilation of the roots and branches.

The old trees at Chatsworth show what can be accomplished by the plan here recommended. It is a curious fact too that, no matter how dwarf the trees may be kept, they are, as a rule, allowed the same extent of border. We could point to plenty of instances where

the roots have nearly 20 ft. of scope, and the heads about half as much, or less. The consequence of this disproportion between the feeding room of the roots and the development permitted to the branches is, of course, an annually recurring rank growth, only kept in check, when opportunity permits, by root pruning. When circumstances compel anyone to keep their trees small and low, the extent of border should also be restricted. In a long Peach case that we looked through not long ago, the front trees had only a 6 ft. trellis, and a 14 ft. border outside, whereas they might have had top room to the same extent had it not been for the fear of shutting out the light from the back wall—a simply exaggerated way of “robbing Peter to pay Paul.” In this case a border 3 ft. wide would have been more suitable for the front trees, as then the trees would have made less rank growth and more bearing wood in this confined condition. The best plan by far, however, is to give the tree tops room. If it be a question of expense in building, take it off the length of the house and add it to the width; but, under any circumstances, let the trees have as much room as they require, or nearly so, and they will amply repay it. When one has to begin cutting back the shoots of a tree annually, in order to keep it within certain bounds, it is then the trouble begins, at least in the case of stone fruits. I have been trying it here for the sake of having a Peach and Nectarine tree in each division; but, although the trees are still young, and have as much room each as is generally allowed in Peach houses, I have given it up, and purpose very shortly throwing our two earliest Peach houses into one, and devoting the whole space to two trees instead of four.—*Field.*

LAYERING VINES.

THE plan of raising Vines from layers just published by a contemporary and credited to Mr. Miller, of Combe Abbey, as its originator, is not new. Mr. Miller's plan is first to encourage long supernumerary shoots from the base of his permanent fruiting Vines, and for which room must be found at the expense of the latter. These rods he layers the following year, each in a row of 10-in. pots set closely together thus getting several young canes from each rod, and which are trained up amongst the permanent Vines till established in their pots and fit to be removed—a system of crowding sadly at variance with that of thin training once advocated by Mr. Miller when his name was oftener before the public as a Grape grower than it is now. Whether the practice is worth advocating for general adoption may be questioned, but it certainly does not differ essentially from that recommended by London some fifty years ago—more or less—and often practised since, though considered rather out of date. London does not recommend the canes to be layered their whole length like Mr. Miller, but like him he selected supernumerary shoots after they had begun to grow, and depressing the most likely layered them in pots at their junction with the old wood, and the result of this practice is thus described. He says “In about a week or ten days roots are found to have proceeded plentifully from the joint of last year's wood, and these may be seen by merely stirring the surface of the earth; or sometimes they may be observed penetrating to its surface. The layer may now be safely detached. Very frequently it contains one or two bunches of Grapes which continue to grow and come to perfection. A layer cut off at the beginning of July generally attains by the end of October a length of from 15 ft. to 20 ft. A new Grape house, therefore, might in this way be as completely furnished with plants in three months as by the usual method, above described, in three years!” It will be seen, therefore, that Mr. Miller has virtually returned to an old plan, and if it answers the purpose well and good; but, according to Mr. Miller's own showing, the Vines produced are no better, if as good, at the end of the first season's growth than Vines produced from eyes. “Some” of his Vines, he states, reached beyond the top of the house the same season, but it is quite a common thing now to see Vines from eyes that have *all* reached the top of a lofty house the same season, and considerably beyond it, and produced canes of such strength that 3 ft. or 4 ft. of bearing wood would be left at pruning time, whereas Mr. Miller found it necessary to cut his down “to within 1 ft. of the ground,” in order to secure a strong growth at the end of the third year from the time he encouraged the supernumerary rods from the permanent Vines that were in their turn layered in pots. An equally good plan of layering pot Vines, which does not entail the necessity of running out long rods from the permanent Vines, as at Combe Abbey, is to layer right and left from unpruned spurs at the base of the Vine. Half-a-dozen Vines may be layered from each Vine if desired, but one or two on each side are enough. By this plan, the whole of the vigour from the parent Vine is directed into the pot plant, and a fine cane is the result. I have seen the plan put into successful practice now and then, and, though not at all new, it is in my opinion, superior to the plan of growing long rods specially for the purpose the year previous. When these are grown

it must necessarily be at a sacrifice of space that could be more profitably devoted to the production of fruit. All things considered, however, and especially the result of Mr. Miller's experiment, I doubt very much if the old layering system will ever be revived in a general way. C.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

The Curl or Blight in Peach Trees.—There can be no question that the past season has been most disastrous to Peach and Nectarine trees on open walls, and doubtless many at the present date will be considering whether it is better to depend solely on crops grown under glass or to replant against open walls, as it is no exaggeration to say that the majority of the trees which I have seen this year out-of-doors are past recovery; in fact, I quite agree with “A. S.” (p. 253) that when Peach trees get into a sickly condition it is good policy to root them out altogether, and start afresh with young, healthy trees. Here Peaches and Nectarines grow extremely well, and at the present time are covered with fine, healthy foliage, and full of bearing wood. We only protected with double fish nets, yet we have very fair crops considering the season; they are late in ripening, but still of good average size and flavour. Our soil is rather a strong adhesive loam, in parts approaching clay, but it rests on a soft, porous, broken stone called *hassock*, that retains moisture in hot seasons, and acts as drainage in wet, cold ones, and to this I attribute the healthy look which our Peach trees possess. It is during the first stages of growth that Peach trees require particular attention, as if the first set of leaves are more or less damaged with curl or insects, growth for the season is checked, and no matter how much wood is made later, it is all but useless, owing to the impossibility of ripening it in the open air.—J. GROOM.

—A writer in the London GARDEN in speaking of the sudden prevalence of curl in the leaves of the Peach and Nectarine, thinks it comes from stagnation of the sap. He justly remarks that it cannot be aphides, as these insects are not always present. Nor does he think it the effect of cold, as its severest attacks were not on the heels of any severe frosts. It is singular how slow observers are in finding out that it is caused by an internal fungus, similar in its operation to the rust in wheat, which first grows inside, and when circumstances favour it bursts through the epidermis and becomes conspicuous. We published the results of some observations on this disease in 1853, in which report it was stated that “the cold-weather theory could not apply, as the disease sometimes appeared after a continued series of warm days, and the young opening leaves showed the disease when they had never been exposed even to a cold night. It made its appearance when no aphides were detected even with a powerful achromatic glass, and in new leaves which had been exposed to fresh air but a few hours and on which the insect had never set foot.” Distinct observations were made about the same time, showing by means of a powerful magnifier the minute parasitic plants in the pulp of the leaf beneath the translucent epidermis, in young leaves opened by the hand for the first time. The remedy, or rather preventive, is the promotion of vigorous growth, feeble trees being most liable to its attack, and strong growers most effectually resisting it.—*Country Gentleman.*

Melons in Pots.—Melons are generally planted out in houses or in hotbeds, both of which entail a considerable amount of time and labour. This season, desiring to have Melons with as little labour as possible, we determined to grow them in pots. About the middle of June our pot Vines being all cleared out, we plunged our Melons (previously prepared for the purpose, and in 11 in. pots) in a bed of leaves, and trained them in the ordinary way up a trellis. We allowed them to grow to their full length before stopping them, and after the laterals showed fruit, they were stopped at the first leaf beyond the fruit. In this way we were able to cut three or four Melons from a plant, averaging three and four lbs. each, and one of them weighed 6 lbs. 2 oz. The Melons are now all cut, and Cucumbers, also in pots, occupy their places. Cucumbers grown in pots are better able to withstand the disease than planted out; at least that is so with us; indeed, we never have been troubled with it. One lot of plants in 11-in. pots are ten months old, and fruiting still. We find Dell's Green Fleshed Melon to do well in pots; on some of our plants we had four beautiful fruits. It is a free setter, strong in constitution, and good in flavour.—J. W. B.

Turkish Trade in Hazel Nuts.—A considerable trade has sprung up of late years between the Trebizond district and Great Britain in the article of Hazel Nuts, which are a very important source of wealth on the coast extending from a little south of Batoum to Kerassund. Upwards of £20,000 worth per annum are shipped to England, the chief supplies of the best nuts coming from Tireboli, between Kerassund and Trebizond. Walnut trees, too, are largely

grown in the forests of Lazistan, partly for the sake of the Nuts, but principally for the Walnut tree knobs, which are much in request in France.—*Times*.

THE INDOOR GARDEN.

INDOOR WATER AND WATER-SIDE VEGETATION.

AQUATIC plants belonging to temperate regions are always interesting objects to look upon, but no combination of them can equal the display produced by a concentration of the aquatics of the Tropics. They produce flowers of almost every shade of colour, and some possess the most striking foliage to be met with in the vegetable kingdom. The *Nymphæas* which constitute so important a family of aquatics, chiefly inhabit the still waters of the northern hemisphere, though in the southern, some few are found, the most remarkable of which is the *Victoria regia* or Water Maize of the Brazilian. It is indigenous to the rivers of Guiana, the tributaries of the Amazon, and the La Plata. It was first discovered by the botanist Haenke in 1801, but it was not until 1837 that it was brought into prominent notice by Schomburgk, who discovered it

12 in. in diameter when fully expanded, and very fragrant. The outer petals are white, while the inner ones and stamens are pink, changing to a deep rose. The flowers are of short duration, seldom opening more than twice; they expand in the afternoon, and remain open until the following morning, and after the final closing they sink below the water to ripen their seed. For the successful culture of this Lily a water temperature of from 80° to 85° is necessary, and a soil rich in organic matter. A compost of good loam, leaf-mould, and thoroughly decayed manure in equal proportions would be the most suitable. A mound should be formed of three loads of this soil heaped over one load of brickbats, and the water requires to be let into the tank and heated several days before planting, which should not be later than the middle of April. In order to have the young plant in a vigorous state at this time, the seed should be sown early in January, using a soil of equal parts loam, sand, and leaf-mould. If attainable several seeds should be sown, and after a slight covering they should be plunged in water having a temperature of from 85° to 90°. Thus situated the seedlings appear in from two to three weeks; three or four of the most promising of them should be selected, and grown on, using 4-in. pots and the same soil as that just named. Although one plant is sufficient, it is better to be provided with others in case of failure; their crowns should be kept just beneath the surface of the water, and fully exposed to light; by the

The Royal Water Lily (*Victoria Regia*) and other Aquatic Vegetation.

in the river Berbice. It was first established in this country in 1848 after several unsuccessful attempts had been made to introduce it. The annexed illustration represents this regal Water Lily in its native habitat, where its vast leaves and flowers are produced so abundantly as to frequently monopolise the entire water surface and impede navigation. Associated with it, are usually the Great Water Reed (*Gynerium saccharoideum*), called in the West Indies the White Rousseau, a plant which bears plume-like panicles 2 ft. or 3 ft. in length; large aquatic Arums (*Philodendrons*) and *Cyclanthads* which, though not really aquatics, occur frequently on the river margins of tropical America.

The *Victoria Regia*, though no doubt a perennial in its native country, is treated as an annual in England. Unlike the other members of the family, it never forms either tubers or rhizomes, but produces in favourable seasons great quantities of seed, which are used extensively for food by the natives of the parts where it is found. Owing to its enormous dimensions, few establishments possess convenience for growing it, but, where space could be afforded, its unique appearance would amply repay all trouble bestowed upon it. It attains its maximum size in August, when its leaf-stalks measure frequently 12 ft. in length, and the leaves from 5 ft. to 6 ft. in diameter. The under surfaces of the leaves are remarkable for their conspicuous ribs, which project to the extent of from 1 in. to 2 in., and divide the leaf into quadrangular compartments. The flowers, which rise a few inches above the water, are from 10 in. to

middle of March they will require a 9-in. pot, which will afford them sufficient root-room until the time for planting out, when they should be furnished with five or six leaves, the largest measuring from 6 in. to 8 in. across; and in planting, the mound of soil should be high enough to allow the leaves to float. In order to secure good seeds the flower when fully expanded requires to be fertilised, and the capsules should be enveloped in muslin, after the decay of the floral whorls, to prevent the seed from escaping.

As an Old World representative of the *Victoria regia* we have *Euryale ferox*, which, though not possessing such noble proportion, has a structure very similar to that of the *Victoria*; it however differs in the arrangement of its inner stamens, violet flowers, and more spiny foliage. It requires precisely the same culture as the Royal Water Lily, but a much less quantity of soil. It is confined to the waters of East India and China.

The Tropical *Nymphæas*, though surrounded by the same conditions, as the foregoing during the growing season, require special treatment as regards soil, potting, and resting. All the species at present in cultivation have perennial tubers, varying from 1 in. to 4 in. in length, and are either globular, oblong, or branched, with a very hard black outer coat. The bases of the unbranched ones are round, with a conical growing point at the opposite end, and the divisions of the branched ones are terminated by growing points. They are gross feeders, and should be potted in a rich loam with a good admixture of leaf-mould and river sand; the stronger growing kinds

require to be grown separately in 15-in. or 18-in. pots, and the smaller sorts either separately in 12-in. pots, or in threes together in the larger sized ones. In potting very little drainage is required, a few large potsherds placed the hollow side downwards are all that is necessary. The pots should be filled firmly to within 3 in. or 4 in. of their rims, then the tubers should be pressed into hollows surrounded with sand to prevent the soil coming in contact with them, and care should be taken to keep the growing points upwards; the pots may then be filled to the rim with soil consisting of equal parts sand and loam. The stronger kinds require a depth of 18 in. of water above the crowns, but the depth above the tenderer sorts should not exceed half that amount. Their after culture consists chiefly in keeping the water at a uniform temperature from 80° to 85°, and clear of Confervæ and dead foliage, and they in common with all the other aquatics enumerated here, never require shading. The seeds, which ripen in two or three weeks after the flower-head sinks beneath the surface of the water, germinate quickly, and the seedlings, if grown on, will bloom the following summer. After the plants have become denuded of foliage, which usually occurs in October or November, the pots should be removed, and placed half their depth in water of a much lower temperature than that in which they have been growing, and the tubers should be left undisturbed until the potting season, but the plants must be kept immersed so long as they remain active.

Several of the finest Nymphaeas which inhabit the waters of the Upper Nile have yet to be introduced. Some of the best of those already in cultivation will be found amongst the following:—

N. Lotus.—The leaves of this are peltate and have a deep sinus or incision at the base, they are orbicular or ovate in outline, and from 4 in. to 6 in. in length; their upper surface is bright green, while the under surface is prominently veined, and ornamented with violet blotches. The flowers, which are pinkish white, are from 4 in. to 6 in. in diameter, and the stamens are yellow with reddish bases. It is common to N. Africa and Tropical Asia.

N. rubra.—This and the three following are said to be varieties of *N. lotus*, but if so they differ widely from the type. The leaves of *N. rubra* are orbicular from 8 in. to 10 in. in breadth, and boldly toothed at the margins; they are brownish-green above, and plum-coloured below with the exception of the veins which are green and very prominent. All the parts of the plant under water are pubescent. The flowers are rosy crimson and from 5 in. to 7 in. in diameter. The sepals are green on the outer side and striped with pink, and the petals are concave and arranged in three whorls. The stamens are numerous and of an orange-brown colour. It is a native of North and East Africa.

N. rosea.—In dimensions this comes near to the preceding, but it varies from it in colour. The leaves are of a bronzy-green with conspicuous green veins, and the flowers are of a clear rose-pink with orange stamens.

N. dentata.—This is a bold free growing plant and one which throws up its young leaves erect and above the water (probably owing to its shallowness). The mature leaves, which are orbicular and from 10 in. to 14 in. across, are bright green, regularly toothed, and free from blotches. The flowers are pure white, and measure from 6 in. to 10 in. in diameter, with elliptic-acute petals, and bright orange stamens. It is a native of West Africa.

N. thermalis.—This partakes of the character of *N. dentata*. Its leaves are from 9 in. to 12 in. in diameter, their upper surface being dark green and the lower one dull green blotched with violet. The flowers, which are white, have oblong-obtuse petals and yellow-stamens. It is found in the river Peeze, in Hungary.

N. Eugenie.—This, though somewhat similar to *N. rosea* attains a greater size. The leaves are from 9 in. to 12 in. in diameter and have an upturned toothed margin, and when young they are blotched with purple on the upper surface and the leaf stalks often grow to 8 ft. in length. In colour the flowers are rose-pink with concave petals 3 in. to 4 in. in length, and reddish orange stamens. It is a plant of garden origin.

N. Devonensis.—This is a very stout-growing plant with dark bronzy leaves, which are frequently 14 in. in breadth, and margined with large spiny teeth. The flowers are from 6 in. to 10 in. in diameter, and of a deep rosy-crimson, with dark orange-red stamens. It is also of garden origin.

N. gigantea minor.—It is doubtful whether the type (*N. gigantea*) is in cultivation, but the introduced plant is the finest of the blue-flowered Nymphaeas. Its leaves, which measure from 8 in. to 12 in. across, are orbicular-ovate in outline, and irregularly toothed at the sides, with the basal lobes overlapping each other. The upper surface is bright green, while the under surface is dull red, with the veins sunk into the substance of the leaf. The flowers are from 6 in. to 8 in. in diameter, and of a clear porcelain blue. The petals are

obovate, semi-transparent, and arranged in numerous whorls. The stamens are numerous, rather small, and of a bluish-white. It is a native of Australia. A noteworthy feature of this plant is that its flowers expand widely, and remain open during the whole of the day, whereas most Nymphaeas rarely open so widely, and are usually closed after mid-day.

N. stellata.—This is a very slender species, but one which produces a great quantity of foliage and flowers. Its leaves, which are roundish-oval, have entire margins, and a deep, narrow sinus; the upper surface is bright green, while the under surface is copiously blotched with violet. The flowers are star-shaped, and of a light azure blue, with a light centre. The petals are lanceolate, and the stamens light blue, with sulphur-coloured anthers. *N. cyanea* is a variety with darker blue flowers. It is a native of East India.

N. scutifolia.—This dwarf-growing species from the Cape has leaves ovate or cordate, and from 6 in. to 8 in. in length, the margins being irregularly jagged and toothed; both surfaces are bright green and glabrous, and free from blotches. The flowers, which have the same character as those of *N. gigantea*, are from 3 in. to 6 in. in diameter when fully expanded, and of a clear porcelain blue.

The Sacred Bean (*Nelumbium speciosum*) is another noble aquatic plant, with large peltate leaves and rosy flowers, elevated on long stalks from 4 ft. to 6 ft. above the water. It inhabits the muddy shores and lagoons of East India, and hence requires to be grown in shallow water. Its rhizomes, which are of great length, produce at intervals stout tubers from 6 in. to 8 in. in length, from which arise the leaves and flowers. Whether for culture in tubs or beds, it requires a depth of 1 ft. or so of sandy loam and leaf mould. Upon this the rhizomes should be spread out and covered to the depth of a few inches with sandy soil. It requires the same temperature as Nymphaeas and no more than 6 in. of water above the soil. It is propagated chiefly by its tubers, which grow rapidly and produce numerous offsets.

In addition to the above there are several other interesting tropical aquatic plants which could be associated with them, such as *Limnocharis Plumieri*, a kind with glaucous foliage and umbels of yellow flowers; *Limnocharis Humboldtii*; *Pontederia crassipes*, a species having kidney-shaped leaves upon inflated foot-stalks; *Pistia stratiotes*, with glaucous pubescent foliage; *Jussiaea natans*, with yellow flowers, allied to the *Oenotheras*; *Ceratopteris thalictroides*, an aquatic Fern, *Cyperus alternifolius*, *Papyrus antiquorum*, and several aquatic Grasses. Z.

AUTUMN TREATMENT OF PELARGONIUMS,

LARGE flowering Pelargoniums generally are holding on much longer than usual, owing, no doubt, to the late spring and the cold and moist summer, with so little of sun heat. September is the month, however, when the plants, cut down early, are in ordinary seasons sufficiently broken into growth to be ready for repotting. After the plants have done blooming, the usual plan is to place them out-of-doors to ripen their wood, laying them on their sides if necessary, in order to facilitate this. When the wood is ripe, and fit for making into cuttings, the plants are cut back hard to the old wood, and suffered to break into growth to the extent of $\frac{1}{2}$ in. or so, when they are ready for repotting. In the act of repotting, cultivators make a practice of shaking out the soil from the roots, and then cutting back the long, hard, spreading roots, leaving all those of a fine, fibry character; the plants are then repotted into a smaller-sized pot than that they were turned out of, the great point being to get as rapid root action as possible, so that no check occurs to the growth of the branches. A pot just large enough to take the roots will be sufficient for the first repotting. In the act of potting it is very important to well drain the pots; the importance of this in its relation to the show Pelargonium can hardly be over-estimated. When the plants are repotted, they require to be kept close for a few days, watering carefully at first, and increasing the supply if demanded by the state of the weather, when the plants begin to make fresh roots.

Soil is a matter of some importance, and an excellent compost can be made up of rich fibrous loam, well decomposed stable manure, some good leaf-mould, and about half-a-pint of rough Bedfordshire sand to a bushel of the compost. Some cultivators of Pelargoniums adopt the practice of storing up for use a quantity of the loam just described and stable manure, either putting it in a heap in layers or mixing it up together, and leaving it for a year before it is used.

When the plants that have been repotted show signs of growing, a slight sprinkling overhead in favourable weather will be of advantage, and plenty of light and air should be given when they can be afforded without harm to the plants. It is the usual practice to stop the shoots when they have grown to the length of 2 in. or 3 in., doing this about November. If a batch of plants are wanted for

specimens to flower in May they should be shifted early in November into 9-in. pots, and not be stopped any more. Any grower having a collection of fifty or so varieties can so arrange his plants, if he has the necessary glass accommodation, as to secure a succession of bloom all through the summer by re-potting late and by judicious stopping. In the nurseries where a large stock of show Pelargoniums has to be provided the months of August and September are busy ones, as the work of propagation has then to be pushed on with energy. Some spent hotbeds are frequently utilised for the early cuttings, and these are put into a good light, sandy soil in lines, and kept shaded from the sun, when they soon make root. The later cuttings are put into store pots, and placed in a small, close house, or on the shelves of the Pelargonium house. As the cuttings root and show signs of growth they are potted off into 3-in. pots, and the strongest into $4\frac{1}{2}$ -in. pots for sale.

As plants can be had in the nurseries in the autumn, I append a list of thirty varieties that would make a rare collection. Some of them are new this year, but the price will no doubt by this time have become somewhat reduced. The following come under this heading: Arthur, Bertie, Crusader, Diana, Dictator, Fortitude, Illuminator, and Silvio. A list of older varieties, but which also includes a few nearly new, may consist of Ambassador, Amethyst, Aurora, Bertha, Claribel, a fine old white variety; Dauntless, Despot, Eurydice, Evelyn, Invincible, Jubilee, Lilian, Lord of the Isles, Magnificent, Negress, of such a hue of dark maroon as to be almost black; Omar Pacha, Patroness, Prince Rupert, Prince of Prussia, a very old white-flowered variety that yet remains a great favourite with many; Sappho, Scottish Chieftain, Sultana, and Viscount. This list can be extended almost indefinitely, but the foregoing selection is a fairly comprehensive one.

R. D.

TREATMENT OF ODONTOGLOSSUMS.

PERMIT me to thank Mr. Goldring for his communication on this subject (p. 248). The *Odontoglossums* are likely to become more extensively cultivated than any other class of *Orchids*, so pretty and attractive are they, as well as comparatively easy to grow, and any information regarding their culture is sure to be welcomed. There is no denying the fact that as at present cultivated in this country, fine plants are produced, but that is no reason for supposing that if treated a little differently still greater success would not be attained. I have all along entertained the opinion that we have kept *Odontoglossums* too cold, too wet, and too dark, and been unnecessarily nervous about subjecting them to a moderately high temperature: and I submit that the fact that they can be grown successfully in the United States, where the summer temperature is high, settles the question. An eminent authority recommends a temperature from 10° to 15° below the mean summer temperature of these islands, whenever that can be managed with the aid of shade and water, but he should have added "ice," for how such a feat is to be accomplished I cannot see, while the plants are still to grow under a glass roof. I rather think the figures usually recommended are greatly exceeded in practice; if it were not so we should not see such fine plants. When in Messrs. Veitch's nursery some time since, I found some of the coolest of the *Odontoglossums* growing and apparently doing well in a pretty warm structure. At one place, the authority I have already quoted says, "the front ventilators, and often the doors as well, are open continuously, unless when there is frost or cutting winds;" in other words, when the thermometer outside was above 32°. Our own experience corresponds more nearly with that of Mr. Goldring.

Up to the present season our *Odontoglossums* have been treated to a temperature about 5° to 10° below the stove temperature. Under this treatment they make two sets of bulbs in the year, and bloom mostly during winter and spring. Some dry small imported pieces of *O. cirrhosum* in the smallest of thumb pots, and with bulbs 1 in. long, and about the same in circumference, made, in two years, bulbs $4\frac{1}{2}$ in. and 5 in. long, and proportionately stout; and during the past winter the same plants, then about three years old, produced spikes bearing fifty fine flowers, some of the varieties very large and fine in the flower. This season, in order to give the cooler system a trial, but principally to suit some other and cooler subjects in the same house, I reduced the temperature during the summer months considerably, turning off the hot water altogether as soon as it was thought safe to do so; and the consequence is the plants have made the least growth they have made yet during a summer, and they will be much later in flowering. I have been so struck with the difference that I had the heat turned on again towards the end of August, and raised the temperature. Very little shade, too, has been given in sunny weather.

Odontoglossum Alexandræ will perhaps stand as cool treatment as any variety. Some imported plants I bought at Steven's last April, and which were just showing signs of starting have made

good growth in the house before spoken of along with *cirrhosum*. In one case the shoots were 10 in. long, and had they received more heat they would have matured their bulbs by this time; yet the habit of this variety warrants us in believing that it would not only stand but be benefited by a considerably higher temperature. According to Williams it is found growing in Bogota between 7000 ft. and 8000 ft. above the level of the sea. Above this height and in a colder region, of course, is situated the capital of Bogota upon an extensive table land described by competent authorities as possessing a "singularly genial and salubrious climate," yielding productions that denote a tolerably high and even temperature throughout the whole year, being situated "on the verge of the equator." And although the country has two rainy seasons in the year, still its fruit and abundant Grain crops indicate periodical dry seasons as well. At a lower and warmer level, but in a climate in other respects similar, is found *Odontoglossum Alexandræ*, a fact which alone warrants the belief that such cool temperatures as have been recommended for this class of plants are unsuitable to their habits and wants, even after making allowance for our darker skies and long winters. In the table lands of Mexico and South America, which are so rich in cool *Orchids*, and especially in *Odontoglossums* perpetual summer reigns, and, we are told, the mean temperature varies exceedingly little, as might be expected in a country where the sun is nearly vertical throughout the year, a fact which must be taken into account in the case of plants from the colder zones of the tropical and sub-tropical regions where a high temperate summer climate only is experienced and no real winter.

C.

WINDOW PLANTS.

WHAT would many of our homes be without flowers? Dull, cheerless, and gloomy, and bereft of one of their principal adornments. That plants have a charm, is evidenced by the careful way in which they are watched and tended even in cottagers windows, where they are frequently crowded together in such a way as to almost shut out the light. When will our architects so design the buildings in which we live that we may have a few plants, which under such circumstances would be a real pleasure to behold? The extra cost of, say a bay window to a house would not be much, and the amount of enjoyment which it would afford is beyond measure. It may be asked, what can any one without a glass structure do to keep up a supply of flowers? to which enquiry I reply, he might do a great deal, as there are many plants that up to near the time at which they come into bloom succeed best out of doors, where they not only come shorter jointed and stocky, but are more floriferous when placed under cover. Take *Fuchsias* and *Pelargoniums* for instance, which if grown in windows become one-sided and drawn, but which, if placed in suitable spots, the one in partial shade under the friendly shelter of a wall and the other in full sun, are always sturdier and finer than they are in any other position. Besides these two, there are hosts of other plants that may be raised from seed annually or kept as bulbs, and for winter there are plenty of hardy subjects that are quite equal in appearance to tender exotics. It will be a help to many perhaps if I enumerate some and give a few particulars as to the way they should be managed, but the chief point at starting is not to attempt too much, as it is more satisfactory to grow a few well than to have a quantity inferior as regards merit.

The great disadvantage under which many labour is not having suitable soil, and yet it is astonishing what results may be attained with even street scrapings, especially if in collecting them they are largely mixed with the droppings from horses, which, containing as they do so much vegetable matter, help greatly in keeping the whole open and porous. All that is necessary to make the compost perfect and suitable for most plants are a few rodules of turfy loam and peat, both of which may be obtained at any nursery at a moderate rate of cost. The mistakes generally made by inexperienced cultivators in potting plants are not using sufficient drainage, and filling the pots too full of soil, but a more frequent complaint perhaps than either is the quantity of water which they give and the way they allow them to stand in it and drown. More plants are injured and lost in this way than in any other, as it not only soddens the earth, but causes the roots to decay. Some will stand it and enjoy it, but they are only the few, such as the well-known *Calla æthiopia* and *Mimulus*, both of which are half aquatic in character. The drainage then being such an important matter for the others, the first preliminary to potting is to carry that part of it out properly, which is best done by first placing an oyster shell over the hole, and covering it to a depth of $\frac{1}{2}$ in. or so with small cinders or charcoal. These will afford a ready outlet for the water, and if the pots do stand in the little that drains through at this time of year it will not be productive of any great harm. In winter, however, it should be poured away, or taken out of the saucers by means of a coarse piece of sponge, which dipped in, soon absorbs the

whole without moving the plants. The common enquiry amongst amateurs is how often shall I water? which leads one to suppose that they expect plants require water with the same regularity as we do our meals; but instead of this there are so many varying circumstances connected with the weather and the varying state of the atmosphere, that no set time can be stated. The amount of leafage, too, that a plant has, and the body of soil its roots are in, have much to do with the quantity of moisture it will take up, and the instructions therefore in regard to this matter must be general. There is one thing of great importance, which is, when water is given it should be in sufficient quantity to wet the entire ball, instead of being administered in dribbles, as is too generally done. A good test of a plant's condition is to try the weight, or rap the pot, which if dry will ring, owing to the shrinkage of soil from its side; but if wet the sound will be heavy and laden. An experienced person, and one accustomed to look after the same plants, soon knows at a glance whether they want water or not, and until the necessary knowledge is gained it is better to err on the safe side than overdo them with water.

S. D.

TWINING FERNS.

(LYGODIUMS.)

THE Twining Ferns are all, with the exception of *Salpichæna volubilis*, included in the genus *Lygodium*. Their fronds become considerably elongated, and cling to and entwine any slender object within their reach, after the fashion of the common Birdweed. Their foliage, which is both delicate in appearance and firm in texture, is remarkable for the variety of incision which may be found on the same plant, and for its highly ornamental character in the fertile state. They are chiefly tropical in distribution, though not one species is common to the Tropics of both the Old and the New World. One species is found as far north as Massachusetts, in North America, and one species is confined to New Zealand.

In general appearance these Ferns depart considerably from the usual Fern character; but on examination it will be seen that this variance arises from a modification of their various parts. All the species have short, creeping, subterranean rhizomes, which branch in all directions, and produce a great quantity of tough black roots. The fronds are given off in

L. dichotomum (fertile frond, natural size).

L. dichotomum (barren frond, one-fifth natural size).

several of the old growths every year to make room for the succession of young fronds. For covering balloon trellises or pillars, or for forming festoons, or furnishing hanging baskets they are specially adapted, and in a dried state few vegetable objects can equal them in elegance. The following eight are a selection from the twelve or fourteen species that are already in cultivation, though, with the exception of two or three, they are rarely met with:—

***L. japonicum*.**—This, though the commonest species in our gardens is one of the best on account of the deep-cutting of its foliage, and its free-growing property. The pinnules, which are triangular and from 6 in. to 9 in. in length, are divided into three or sometimes five pairs of triangular segments, which are inserted alternately. The lowest segments are deeply pinnatifid, with the lobes auricled at the base, and the tips ending in linear toothed points. The upper lobes are simply linear, or have two or sometimes three auricles at their bases. The lobes of the barren pinnules are finely toothed, while those of the fertile ones are fimbriated with small scaly spikes, which contain the spores. The plant may be grown to maturity in a 6-in. pot, and with this amount of accommodation will often produce a column of foliage 10 ft. to 12 ft. in height. It is a native of Japan, Ceylon, and N. Australia.

***L. venustum*.**—The segments of this plant are similar to those of the foregoing, but they are larger and have a different arrangement. The pinnules are oblong in outline and are from 9 in. to 12 in. in length, with three or rarely four pairs of lateral alternate segments and a terminal one, which is much larger than the rest and deeply tripartite. The lateral segments, which are shortly stalked, are palmate with the central lobe much enlarged, or oblong and pinnatifid at the base. The lobes of the barren pinnules are regularly and bluntly toothed, while those of the fertile pinnules are closely fringed small plaited spikes bearing the spores. The pinnæ of the plant are placed wide apart and are all densely hairy, and in this respect it differs from all the rest. It is a native of the West Indies, Mexico, and Brazil.

***L. scandens*.**—This species is somewhat rare in collections, and *L. japonicum* is frequently sold for it. The pinnules are simply pinnate, with two, three, or four-stalked segments on each side. The segments are of a light glaucous-green, and very variable in shape, being either cordate, oblong, or lanceolate; they are arranged alternately upon the zig-zag rachis, and the upper pair are frequently united. In the fertile state the segments are cordate or ovate, with their margins fringed with the sporiferous spikes, which resemble minute strings of green beads. With liberal treatment the fronds of this plant grow to the length of 20 ft. or more, retaining its lower

L. dichotomum (fertile frond, one-fifth natural size).

quick succession, the rachis of which often grows to the height of 20 ft. or 30 ft. The pinnæ, which are arranged alternately on the rachis, are rarely developed beyond the first pair of pinnules, though in the case of very old rachises the pinnæ sometimes branch again. These pinnules supply the place of an entire frond, and as one is the exact counterpart of the other, it will only be necessary in speaking of the foliage of the species enumerated below to describe the pin-

pinnules quite fresh-looking. It is a native of China, the Malayan Island, and West Africa.

L. dichotomum.—This is the stoutest of the introduced species. The main rachis usually attains the height of 20 ft. The pinnules are digitate, with from five to eight linear-lanceolate segments, which are of a bright emerald green. The segments of the pinnules nearest the base of the plant are usually 8 in. to 10 in. in

L. pinnatifidum.—In habit this comes near the preceding, and is nearly as vigorous. The pinnules are pinnate, and from 6 in. to 8 in. in length, with from five to seven oblong, alternate, shortly-stalked segments, the upper two of which are usually inserted at the same points, or sometimes united at the base. The segments of the barren pinnules are finely serrated, while those of the fertile pinnules are both serrated and fringed with the sporiferous spikes. The main

Lygodium palmatum

length, while those of the upper pinnules are about half that length. The segments of the fertile pinnules are much reduced in width, with their margins closely fringed with the scaly sporiferous spikes. The plant rarely becomes fertile until it reaches the age of from five to seven years from the sporeling state, but it is a strikingly beautiful climber in all its stages. It is a native of Hong Kong and the Malayan Archipelago.

rachis is reddish-brown, and the foliage is coriaceous, and of a dull light green. It is a native of the Himalayas, Malacca, North Australia, and West Africa.

L. palmatum.—In favourable situations this species is hardy in this country, though in structure it is the most delicate of the genus. The main rachis is straw-coloured and very slender, and the foliage is of a light glaucous green above, and paler below. The pinnules,

which are simply palmate with a cordate base, have from five to seven oblong-obtuse wavy lobes, the lowest of which are small and rudimentary. The leafy portion of the fertile pinnules—which are borne by this plant in a very young state—is almost entirely absorbed by the mass of sporiferous spikes, which hang in clusters resembling birds' claws. The foliage of this plant is collected in great quantities in the state of Massachusetts, North America, and when pressed is used as an article of ornament for the decoration of apartments. It is a native of the Eastern States from Massachusetts to Florida.

L. reticulatum.—This as its name implies has netted veins, a peculiarity also possessed by the following species. The main rachis becomes when old very tenacious, and resembles copper wire. The pinnules are simply pinnate, with five or seven pairs of sessile, triangular, or lanceolate segments, which are cordate at the base, and extend beyond the rachis. The uppermost pair are frequently united at the base. They are of a dull light green above, and bright green below. The fertile segments are cordate, and thickly fringed with the sporiferous spikes. It is a very rare plant, and difficult to propagate either by spores or division. It is a native of Polynesia and east tropical Australia.

L. lanceolatum.—The pinnules of this species, which have a tendency to point upwards, are from 4 in. to 6 in. in length, with a zig-zag rachis; and bear on the lower part of the plant from three to six segments each, while on the upper part the number is reduced to two, or sometimes a bipartite one. The segments are lanceolate and broadly crenelated, and are attached to the rachis by short stalks. The fertile segments have the margins fringed with the scaly spikes, but they are rather smaller in this than in the foregoing. The foliage is of a glossy green both above and below. It is a native of Madagascar. C. M.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Ferns in Borders, Pots, and Passages in Glass-houses.—The excellent plan of covering surfaces usually left bare with graceful Ferns and Mosses is well carried out at Bodogon by Mr. Ellam. The effect of the beds in which Palms, &c., are planted out is greatly enhanced by the surface being quite covered with Ferns of various sizes. In one case where the pipes rise so near the front of a house that no shelf for plants could be raised above them, a box of soil is placed the whole way along, and from it grow drooping Ferns, Mosses, and trailers. In another house, a passage covered by an iron grating is full of beautiful plants of our British Maiden-hair, the fronds of which are borne on longer stems than when grown in pots, and thus become more useful for certain kinds of decoration. Large pots containing specimen plants are also embellished with fragile kinds which will not exhaust the soil.

Violets from Runners.—Violets are abundantly grown in the gardens at Penrhyn Castle from the points of the runners inserted rather closely in frames. Put in in August they flower freely through the winter. V. *Victoria Regina* evidently does well in this way.

Two Good Indoor Dracænas.—I would strongly recommend D. *Bausei* and D. *Baptisti* to the attention of growers of this extremely useful family of ornamental-foliaged plants. The first-mentioned variety is compact in habit, and the leaves are broad and finely coloured, thus rendering it a highly suitable subject for room and dinner-table decoration. It requires to be isolated in order that its beauty may be fully appreciated; whereas its congener *Baptisti* is, on the contrary seen to best advantage when associated with other fine-foliaged plants of a light and graceful habit of growth, such as Ferns, Palms, &c. When thus placed it presents a striking and very ornamental appearance. These two varieties will undoubtedly, when well known, become great favourites for decorative purposes.—BY FLEET.

Davallia Mooreana as a Room Plant.—This strong and graceful Fern withstands the dry air of living rooms better than most other Ferns, hardy or tender.

Solanum capicastrum.—Where berry bearing Solanums are grown for winter decoration they should now be full of fruit just ready to change colour, so that when moved under glass they may quickly become available for decorative purposes. Although good plants may be grown the first year from seed, they are much easier formed into good sized shapely specimens the second season. Young plants intended for cutting down should be kept rather dry and cool during the winter months; about February they should be cut back rather closely, introduced into gentle heat, and slightly syringed until they break into young growth, when they should be shaken out and repotted in good rich soil packed firmly. A light shelf near the glass is the best position for them, and as the days lengthen they should be gradually inured to more air until they can be fully exposed; but in such a season as the present they are best plunged

in cold pits so that the lights may be drawn over them during heavy rains. When a good supply of berries is set, a top dressing of rich soil or rotten manure will greatly assist their swelling and give the leaves a richer colour. When well grown, Solanums are useful plants for conservatory or drawing-room decoration as they keep in perfect health in any cool structure from which frost is excluded. They make excellent dinner-table plants, their brilliantly coloured berries looking extremely well under artificial light, and at Christmas they are suitable either for church or house decoration.—J. GROOM, *Linton*.

Streptocarpus floribundus.—I observe (p. 265) that this is classed amongst stove plants. Instead, however, of its being a stove plant, it is simply a greenhouse or cold frame plant, needing not the least artificial heat in summer, and only a greenhouse temperature in winter. It is such a charming free-blooming plant that it should be widely grown, especially by those whose glass houses are limited to the growth of hardy or semi-hardy plants. I have no doubt that it would do well on rockwork or in sheltered places in the open air in summer. Plants of it may be raised from seed, which should be sown in a gentle heat in spring; these will bloom in the autumn and make fine plants the following summer.—A. D.

THE FLOWER GARDEN.

PLANTING OUT PRIMROSES, POLYANTHUSES, &c., FROM POTS.

I HAVE long been an advocate for growing some of these beautiful plants in pots to flower in winter and spring under glass; but I do not recommend any cultivator, except under unavoidable circumstances, to continue the plants in pots all through the summer. It greatly assists them to plant them out in May, allowing them to remain in the open air till September or early in October. Such a practice gives them a kind of liberty which they appear to enjoy, *i.e.*, if they are planted out in a suitable place and in the right sort of soil. In my little garden I have some lines of pyramid Apple, Pear, and Plum trees 7 ft. apart, and in the shade of these I make up beds raised 3 in. or 4 in. above the ground level, and some 2½ ft. in width. These beds are deeply dug and thrown up rough in winter, and occasionally dressed with soot. In spring they are levelled down, and a layer of leaf-mould, sand sifted from gravel, and soil from the potting bench, 2 in. to 3 in. in depth, is placed over the top. The plants are turned out of pots, the crocks removed, a sufficient quantity of the soil is crumbled away with the fingers to leave the exterior roots free, and then planted out 6 in. to 8 in. apart, digging a deep hole and placing some leaf-mould and sand about the roots; the plants are then pressed firmly into the soil, and a little deeply into it. When the hot weather comes, some Cocoa-fibre is placed on the surface, and while the weather is dry, the plants are always well watered overhead. Treated in this way they succeed well and throw out numerous roots near the surface, which feeding on the fresh soil results in a healthful vigour. They are kept cool, have plenty of fresh air and occasional sunshine, and the danger from drought and consequent attacks of red spider, &c., which menace the plants when confined in pots, is reduced to a minimum.

Any plants that will bear division—that is to say, that have thrown up side shoots which have developed into independent-rooted plants—can be removed and planted out also; but unless the pieces divide freely, and, in addition, are well rooted, it is best to defer this work till the autumn, at the time of re-potting for spring blooming. Vigorous well-grown plants will furnish side shoots both in spring and autumn, and thus make rapid increase. I find small side shoots that are only imperfectly rooted, whether of Primroses, Polyanthuses, or Auriculas, do best put round the sides of store pots in a light sandy soil, where they soon establish themselves, and grow into nice plants by the autumn. Such store pots are best put into a cold frame, in a shady place, or stood out on an ash bed in a cool spot, where they can be protected from heavy rains.

Those who grow these plants in pots, but have no convenience for planting them out, will do well to repot their plants by the time they have done flowering, as the soil gets sour by that time, and the roots require a change. It is best to shake the soil from the roots, and take off any rooted side-pieces, trimming the "carrot" as the main root is termed, as in the case of Auriculas, for it is from the main root near the leaves that the young roots that may be said to build up the renewing plant come first, and repotting in smaller pots, so that the plants may become firmly rooted and well-established as quickly as possible. These should occupy a cool frame in a shady place, or be plunged in a bed of Cocoa-nut fibre or ashes in the open air. The divided pieces can be treated as previously recommended. The plants potted as just described should

have another shift into a larger size in August, that is, into the blooming pots. My main reason for recommending a small shift in the early part of the summer is that it is best to get the plants into root action as soon as possible, and the smaller the pots the quicker is this likely to come about. It is during the summer that the plants acquire the strength which ensures bud and blossom in spring.

In the autumn, whether in the act of potting up from the open ground—in which case the cultivator should be very careful not to over-pot at that season of the year—or shifting from the pots in which the plants have been growing in summer, the pots should be well drained. The plants should be potted firmly in a soil made up of good fibry loam, leaf-mould, thoroughly decomposed manure and sand, and the surface of the soil should be at least $\frac{3}{4}$ in. below the pots. This secures ample space for giving water, as well as some top-dressing in spring.

It is better to winter the plants in a cold frame, where they can be kept moist, cool, and airy, than in an ordinary greenhouse; if the latter be kept at all in a comfortable state of warmth, the plants are apt to become affected with green fly and the foliage to go sickly. They do far better in a cold frame, where they can be protected from very hard frost, until they begin to show their flowers in early spring; and then they can be taken to the greenhouse and hastened on into bloom.

R. D.

MILLA LONGIPES.

THOUGH this new introduction from California cannot vie in beauty of colour with its congeners, which have deservedly become such popular hardy flowers; it is, nevertheless, highly desirable on account

Umbel or Flower-head of *Milla longipes* (one-third natural size).

of the singularly elegant appearance of its large umbels of flowers, as may be seen by the accompanying woodcut. The flowers are about the size of a sixpenny piece, of pearly white inside and heavily marked on the outside with dull red streaks. When seen in quantity in bright sunshine they have a very pretty effect. My first acquaintance with it was about two years ago, when seeds of it were sent to Kew from the Harvard University Gardens. Since then it has flowered in several collections, and was exhibited during the present summer at South Kensington by Mr. Elwes. A frameful of it growing in Messrs. Barr & Sugden's grounds at Tooting, afforded us material for preparing the annexed engraving. It thrives in any light warm soil, and may be easily raised from seed, and connected with this is the fact that it may be thus raised and flowered the succeeding season, an occurrence very unusual with most bulbous plants, except in the case of annual kinds, such as *Bulbine annua*.

W. G

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Linaria alpina.—This is a little gem of a plant, not so well known as it deserves to be. When once introduced into gardens or planted on rockwork, it is certain to hold its own, for plants of it are certain to come up here and there wherever it has been introduced. It is a lovely plant in a pot when well managed; to effect this it should be grown in almost gravel or lime elips, and, being of a slender, diffuse habit, the delicate branches should, when young be well pinched in, and the branches neatly pegged all over the surface of the pot. Treated thus, it is, as has been stated, one of the loveliest plants that can be grown in a pot. Its silvery glaucous foliage, and its conspicuous violet flowers with deep orange throats, at once proclaim it one of the choicest of Alpines.—T. WILLIAMS.

Tritoma Uvaria.—The extraordinarily rapid growth of the flower-stalks of the *Tritoma* is certainly worth notice. We have some very large clumps of it here, carrying from ten to twenty brilliant orange-scarlet flower-heads, which make a grand display for many weeks. On Sunday the 7th inst. the flower-buds were just showing above the leaves, and on the 14th, they had grown during one week from 3 ft. to 3 ft. 4 in., or at the rate of from 5 in. to 6 in. per day. Last week they made about half this growth, and are now in full flower, the stalks being from 6 ft. to 7 ft. high.—BROCKHURST.

Columbines in the Midland Counties.—Mr. Douglas remarks (p. 264) that *A. glandulosa* does not grow well in the south of England, but does well north of Aberdeen; it succeeds very well at Didsbury, near Manchester; we have a large stock of it here, many of the plants being self sown. *A. chrysantha* and *aurea* have flowered well here this summer, and they remain in bloom much longer than *A. cœrulea*. *A. Skinneri* has been very beautiful, and continued long in flower. We have a good many varieties of a stellate form of flower, which I have not seen noticed in any of the catalogues. One of these we exhibited at the Manchester show in June last. It grows nearly 4 ft. high, and has a beautiful habit, and abundant flowers. The *Aquilegias* are well worth very careful attention, as all of them are beautiful, and I think they are capable of much greater development. The following are the varieties we have growing:—*A. alba plena*, *alpina*, *aurea*, *bicolor*, *chrysantha*, *cœrulea*, *hybrida*, *canadensis*, *californica*, *glandulosa*, *hortensis*, *h. stellaria*, *nigrescens*, *olympica*, *pyrenaica*, *sibirica*, *Skinneri*, *variegata*, *viridiflora*, and *Vervœnæana*; just twenty varieties. Seedlings are growing from self-sown seed all over the place, so we ought to have some curious hybrids bye and bye. They are all quite hardy as we did not lose one sort during the severe weather last winter in the open garden.—BROCKHURST.

Yucca Ellacombei.—“B.’s” suggestion (p. 257) that I should send flower-spikes and leaves of this *Yucca* to Mr. Baker, at Kew, is undoubtedly a good one; but unfortunately this must be postponed till next season, as the flowers have all died off. “B.” mentions that it has been spoken of as *Y. Ellacombei* var. *tortulosa*. It has, but in error; the specimen sent to THE GARDEN office (p. 216) was indistinctly labelled; it should have been *Y. Ellacombei* syn. *tortulosa*. I have not the pleasure of knowing who “B.” may be, but on receipt of his “polite note” I shall be happy to send him a plant of the *Yucca*. With reference to the nomenclature, I shall satisfy myself with calling it *Y. Ellacombei* or *Y. tortulina* until those who are more competent have decided that some other name is the correct one.—ROBERT A. OSBORN, Fulham.

Gold Laced Polyanthus.—I observe that Mr. Douglas favours the growing of these for exhibition in pots large enough to enable the plant to carry several trusses and thus make a larger display of flower, a course different from that acted on by the old northern florists. I have no doubt that Mr. Douglas bases his advice upon the fact that at the last Auricula show at South Kensington, he exhibited such plants, and with them received the highest award given on the occasion. Now I put my own opinion forward with some hesitation, because I am but a novice in this particular branch of floriculture, but I certainly imagined that the flowers on Mr. Douglas's plants showed size and abundance at the expense of refinement, that the blooms were either a little past their best, or had lost quality and had gained size and coarseness. I am aware that in saying this much, I am treading upon dangerous ground, because the plants were adjudicated upon by eminent Polyanthus growers; still it appeared to me that they were placed first not so much because they were so good as because the others shown were so poor. In the preceding year several of the northern growers staged plants, and nothing shown last spring could at all approach in quality and refinement of colour, and marking their examples of *Lanceer*, *Cheshire Favourite*, and *Exile*, grown to show the very highest qualities of each sort with a few blooms only. It is all very well to ask for greater size in the Gold laced Polyanthus, and more flower; these are common demands, but existing kinds can only furnish these

features at the expense of quality. I think amateur cultivators, and specially novices, will do well not to work in that direction too freely, it may lead to considerable disappointment. A Gold laced Polyanthus, however small, is a gem if its colour and markings are perfect. If these are the reverse it is but rubbish, howsoever large the pips may be, and howsoever abundantly produced.—A. D.

—There are a few other sorts of Polyanthus which, I think, may be added with advantage to the list which Mr. Douglas gives (see p. 255). Formosa is a great favourite in the north and flowered exceedingly well with me last year. Pearson's Alexandra is also said to be a very fine sort, but I have never seen it. William IV. is a good variety. Barkas's Bonny Bess is a Tyne-side favourite, which is fairly good. For perfect beauty of form and regularity of laeing I think Cheshire Favourite bears the palm; nothing can be more beautiful than a fine mass of this kind. I should add to Mr. Douglas's recipe for potting, some good leaf mould. That is the natural soil for both Polyanthus and Primroses, and is far before rotten manure, although a little of that also helps. Manure is, however, apt to foster luxuriance of leaf instead of beauty and perfection in the flower. I think that Mr. Douglas's remarks upon removing all the trusses save one may be open to misconception. It is, I believe, the practice to let all the trusses grow on, unless for exhibition; and if for showing, it is then usual to remove all but the number of pips required for exhibition. I always understand that this is done only for fear of the judges, as one could not be sure that they would select the seven best pips, if we exhibited more than the stipulated number. It requires a very large number of plants to choose from if you are to be a successful exhibitor, and if you were bound to show more than six or seven pips of perfect form, it would be difficult indeed.—BROCKHURST.

Calceolaria Golden Gem.—We grow this *Calceolaria* largely; it has been most effective during the whole season and has been quite free from the disease which in some seasons works such havoc with *Calceolarias*. It is dwarf and sturdy in habit and a free and continuous bloomer. We winter our plants of it in cold frames, so that they never get any artificial heat and they are certainly preferable to those drawn up in heated glass houses. We insert the cuttings in October and cover with glass lights, keeping them close until they are rooted, after which they are exposed on all favourable occasions and well covered with litter during frost.—J. GROOM.

Treatment of Alternantheras.—Complaints from all parts seem to be abundant regarding the failure of these; we must therefore consider ourselves fortunate, for here *Alternantheras* have been all that could be desired. Our mode of treating them differs somewhat from that recommended by Mr. Groom (p. 262). At planting out time we take off as many cuttings as we think sufficient for our stock, and put them into boxes, and when put into heat they soon strike. After that, they are removed to a cold frame for the summer, where they require no further attention beyond watering them. About the end of September we place them in warmer quarters for the winter, and in spring we can get thousands of cuttings from them.—J. W. B.

Hemerocallis flava.—I wonder why this truly handsome Day Lily has not been brought to notice as a plant deserving of naturalisation. It is without doubt one of the handsomest hardy herbaceous plants known. Its large clear yellow trumpets, something in the way of *Lilium longiflorum*, render it very conspicuous, and it is deliciously fragrant. It is very hardy, growing anywhere, but it is really an aquatic, growing to perfection in shallow water, and where introduced it may easily be imagined what effect masses of it would have on the margins of ditches, ponds, and such places; even its copious drooping foliage is handsome.—THOS. WILLIAMS.

Pot Marigolds.—Hardy and showy as are the pot Marigolds, they have never been placed in the position of florists' flowers, yet they possess many pleasing features, and the commonest double flower shows that it has form, neat, well-regulated petals, and needs but those in greater redundancy to make a perfect flower. Probably it is a drawback that hitherto there has been found in it, but the one monotonous shade of orange-yellow, but although several other shades have been raised they have never become common. When recently in a farmhouse garden in Kent, I saw a very beautiful double variety, the flowers of which were of good form and well filled, the petals being of a pale lemon hue regularly and perfectly striped on either side with deep orange. That it was a well fixed kind was evident from the fact that every seedling plant that had bloomed produced flowers having these markings. I secured a few plants and some seed, several of the former being about to bloom, and was not a little pleased thus to have found to hand such a markedly improved variety of a plant that I had long admired for its free-flowering and hardy qualities. The variety recently shown by the Messrs. Vilmorin, of Paris, under the name of Meteor, would appear from the published description to be identical with the striped kind that I have. Howsoever it may have originated is of little moment when compared with the

fact that it does exist, and that it is really a most charming plant for the hardy flower garden. The regularity of its markings almost exceeds those of the very best of French Marigolds.—A. D.

PLATE CXCIX.

PHÆDRANASSA CHLORACEA.

Drawn by CONSTANCE PIERREFONT.

ALL lovers of easily cultivated greenhouse bulbs will be pleased to note the reintroduction of this beautiful Amaryllid by Messrs. E. G. Henderson & Son, of Maida Vale, who exhibited a good specimen of it at the May show of the Royal Botanic Society this year, when it was awarded a first class certificate; it was exhibited as *P. chloracea vera* in order to distinguish it from the many worthless sorts often supplied as *P. chloracea*, most of which do not bear the slightest resemblance to the true variety. It is, I may mention, a very robust growing free flowering plant and one which thrives well in an ordinary greenhouse along with *Ismenes*, &c. A mixture of two-thirds turfy loam and one-third peat with a little sand forms a suitable compost for it, and indeed for most other bulbs of its class, and when once well established it should not be repotted so long as it continues in good health. Treated in this manner the annual production of its showy flowers will be ensured. It was imported from a cool part of the Andes of Peru.

JAMES O'BRIEN.

[According to Mr. Baker in his "New Key to the Amaryllidaceæ" there are but two other species, viz., *P. Carmioli* and *P. viridiflora*, both of which are novelties. *P. obtusa* and *P. multiflora* are but forms of *P. chloracea*. Our plate was prepared from specimens supplied from Pine Apple Nursery, Maida Vale.]

GARDENING FOR THE WEEK.

Greenhouse.

Winter Quarters for Plants of Various Kinds.—Plants of all descriptions have this summer made softer growth than usual owing to the much less sun than ordinary to which they have been subjected. Those that have stood in pits where the lights can be taken off in the daytime should be kept under such conditions so long as they are safe from frost, for cool treatment of this description is best calculated to bring about a desirable cessation from growth and to aid in ripening the wood. In the southern parts of the kingdom and on the coast, where frosty nights do not usually occur until later, it is not requisite to take the plants in so soon as in less favoured localities; this, with the appearance of the weather, will point to the necessary time for getting everything where it will be secure for the winter. On fine autumns, where a few loose lights could be placed over them to ward off heavy rains, I have kept Heaths out till October was far advanced and where there is the means of giving them this slight protection they are better out, especially where Heaths have not a house to themselves but have to be accommodated along with other plants that need to be kept a little closer. In getting plants into their winter quarters it is necessary to proceed systematically, placing the different kinds in the positions best suited to them, such subjects for instance, as Azaleas and Epacris with any other hard-wooded greenhouse plants that form their bloom-buds in the autumn and whose shoots are quite or all-but dormant through the winter, although in common with all others of a kindred character, are benefitted by a situation in which they will receive a full volume of light; yet where the entire stock cannot be so accommodated they will do standing under worse conditions in this respect than any plants whose shoots keep on growing slowly throughout the winter, and the flower bud development of which takes place wholly during the winter months. Heaths, with the exception of a few varieties, make no shoot growth in the winter, still it is during this time that almost the whole of the flower formation is going on, and on this account they cannot be kept too near the glass in the best house that can be afforded them. Pelargoniums, though totally different from the last named subjects, making as they do the greater portion of their shoots in the winter and spring, need to be under the full influence of light. *Kalosanthes*, now not near so much cultivated for general decorative purposes as they deserve to be, although they make comparatively little shoot extension in the winter, yet usually bloom much more profusely when placed where their heads will be within a few inches of the glass from this time until spring. Late-flowering *Camellias*, and any of the *Citrus* family will do now for some months with comparatively little light. I particularise these things with a view to its being of some use

PHÆDRANASSA CHLORACEA (HERBERT)

to amateurs and beginners in plant cultivation, who will find it much more convenient and conducive to the well-being of their plants to consider the respective requirements of the different subjects they have to deal with, and thus at the present time put each in the most suitable winter quarters, so that there will be no necessity to again upset the houses by making any alterations in the positions the various plants occupy. In most places, large or small, such a number of plants have to be wintered as makes it necessary to place a portion under less favourable conditions than they would be subjected to, were there alike room to treat all in the most desirable way. Yet much may be done with a mixed collection of plants to bring them successfully through the winter, when the requirements of each are considered; the reverse of this is often observable, when at the time of housing they are crammed in anyhow by mere haphazard. Another matter essentially necessary at the time of getting the plants in, is to see that all are free from insects, such as aphides, thrips, and red spider; for though these will not for some months increase nearly so fast as during the spring and summer, yet affected plants communicate them to others that stand near, on which they remain in a more or less dormant state, ready to increase in vast numbers at the return of the growing season, when the softer condition of the plants makes it much more difficult to deal with them, entailing a correspondingly greater amount of labour.

Double Primulas.—These are not nearly so much grown as the single varieties, which, to some extent, may be accounted for by their much less showy character and liability to damp off unless somewhat differently treated from the single kinds, but where the flowers are needed for cutting, the advantages are very much in favour of the double ones, as they do not drop nearly so quick. Where a little more warmth can be given them all through the winter, little difficulty will be found with them. Nothing answers so well as a small pit or house where they can be kept to themselves, or in company with Cyclamens that are wanted to flower early, kept near the light with a moderate admission of air on fine days and a night temperature of from 45 to 50°; damp will not give much trouble, and the plants will keep on thriving, making double the progress possible in ordinary greenhouse warmth. Such persistent flowerers are they that the smallest examples keep on blooming, but where the plants are not wanted until later on, the flowers should be picked out as soon as formed, which will much accelerate their attaining size. Weak manure water will be found of great use to them.

Lilies.—Many of the late-flowering varieties have been unusually late this season, scarcely having time to mature their leaves properly. As they die down whatever potting or renewal of the surface soil is required, will be much better carried out now than later on, as when they are put in out-of-the-way places where many are compelled to accommodate them, the re-potting and consequent disturbance of the roots get deferred until fibres are being made, when much injury is done. All the kinds that form young bulbs on the lower part of the flower stem that is under the soil, but above the principal bulbs, should be gone over now with a view to remove these, whether the main roots require potting or not, as if the young bulbs are allowed to remain, the pots, in a single season get so crowded that the soil is not capable of sustaining the flowering bulbs in the way they require. Different growers use different descriptions of soil for them. I have found strong loam with a little admixture of leaf-mould, rotten manure, and sand to grow all the strong-growing kinds stouter, and so to enable them to produce a greater number of flowers than peat, and also to induce them to increase faster. The weaker-rooting, less free-growing kinds peat seems to suit best. Attention as to re-potting soon after the tops have decayed is particularly advisable in the case of bulbs that have only this summer made their first growth after being imported. These, especially *L. auratum*, frequently make growth and sometimes even produce a flower or two, at the same time forming little or no roots. Bulbs of this description very seldom live beyond the first season, and they are usually such as have begun to push roots after arriving in this country previous to being potted, and the young tender fibres being injured before or at the time of potting died right back, when through inability in the bulbs to push more roots, there was nothing to support them, the shoot growth they made, generally being the exhaustive and last efforts the plants were able to make. I should advise all who purchase imported Lilies, and this species in particular, to get and immediately pot them as soon as the first importations arrive, as with these, so far as my own experience and observation go, I have seen by far the most satisfactory results. Another matter I would impress upon young cultivators is the absolute necessity for using small pots; even in the case of established plants, that is, those which have been grown in the country some time, it frequently happens that they are over-potted.

Scented-leaved Pelargoniums.—Many of the winter-flowering plants forced or otherwise and required for cutting, are weak in perfume, and it often happens since Orchids are so much used for the

purpose, that a handsome-looking bouquet is all but scentless. This is easily remedied where a sufficient quantity of the sweet-leaved *Pelargoniums* are grown to meet the requirements of the very different tastes in this matter, from the rose perfumed *P. graveolens*, and the varieties of *P. capitatum* to the ordinary citron and Lemon-scented kinds; these, if well managed, so as to get stout healthy growth in them with ample clean foliage that has never been allowed to get infested with aphides, and if kept under glass early in the season and then turned out in the open air during the latter part of summer, will get their leaves hardened enough to keep fresh in a cut state for some days, but though so easily grown they need sufficient attention to have them in the best condition.

Callas.—Where these are grown on the system of division in the spring, and planting in the open ground with a view to their being potted up in the autumn, they should at once be lifted and placed in the pots in which they are to bloom; these need not be larger than will just admit their roots and a moderate amount of soil without too much cramping, as when they have flowered through the winter and spring they will again be turned out-of-doors as before. They are water-loving plants, and will bear the soil well moistening immediately they are potted; grown in this way their leaves are very stout, and the petioles consequently are much less likely to be broken, and their handsome foliage, when perfect, adds so much to their appearance when in bloom, that it is worth a little extra labour to keep it whole. A single stick to each pot, so as to just support the leaves, will be found sufficient to ensure this. The plants when potted may be placed close in any house or pit available, such as a Vinery, where they can remain till the roots have got established, and after a time be placed in heat to bring them into flower as required.

Greenhouse and Conservatory Climbers, such as flower in the summer, admitting of their being cut in at this season possess an advantage deserving of consideration in making a selection of plants for the purpose, for during the bright summer months where not allowed to cover the roof too closely, they, to some extent, supply the place of ordinary shading to keep the general occupants of the house, when in flower, from being too much exposed to the sun. Those that thus bloom during the summer months, and will bear cutting in more or less yearly, should now have their shoots shortened, an operation necessary to admit as much light as possible to the other occupants of the house through the winter. Amongst them will be found the summer-flowering *Bignonias*, *Hoveas*, *Hardenbergias*, *Kennedias*, *Passifloras*, *Tecsonias*, *Plumbago capensis*, &c. The beautiful sweet-scented *Mandevilla suaveolens*, although a plant very subject to red spider, is well worthy of all the attention necessary to keep it clear from this pest, for when it has attained a considerable size, it will continue for many weeks through the autumn, producing a succession of its white trumpet-shaped flowers. *Swainsonas*, *Habrothamnus elegans*, *Jasminums*, *Chianthus puniceus*, *Chorozemas*, and *Acacias*, are also all good. It is not desirable at this season to cut more away than is absolutely necessary, as whatever branches are removed will tend to lessen the quantity of flower they are likely to produce in the spring, but where these have grown too large for the situation they occupy either trained on pillars or on the roof they should be judiciously thinned out; so treated they are much better both in appearance and reality than where an attempt is made to tie them in so close as to make them look stiff and formal. All plants of the above character should, where they require it, now have a thorough clearing from insects, as from their position overhanging other plants they are certain to communicate whatever they may be affected with to the plants standing beneath them. Should any happen to be infested with that worst of all pests, white scale, the most effectual method of dealing with it, is to cut them in so far as to admit of their being taken down from the wires that support them, and have the whole of their heads immersed in liquid insecticide sufficiently strong to kill the insect; the application of any liquid by sponge or brush however effectual it may be for the destruction of this species of scale can scarcely ever be used so as to completely eradicate it, from the difficulty of so getting the dressing to reach every part infested, whereas if dipped overhead the entire surface of the plant is reached. This insect is so hard to kill that even when the plants are close cut in, so as to leave nothing but the hard wood, it often takes several applications before all are destroyed. Now when growth has ceased by beginning early and repeating the dressing through the winter, affected plants may be cleaned.

Flower Garden.

Auriculas.—“Delta” states (p. 255) that the *Auricula* aphid is very destructive to his plants, and recommends watering the soil in the pots with paraffin as a cure for it. I hope that *Auricula* growers will not follow his advice. Paraffin is a dangerous substance, and I am much surprised that it should be recommended so much as it has been by practical gardeners. If the woolly aphid were to appear on any of our plants, I would turn them out of their pots and wash the

T. BAINES.

roots well with soapy water. Then, when they had been permitted to dry for half an hour, I would wash again with clean rain-water. "Delta" seems to think that even if his plants were clean they could not be kept so, because the pest would attack them again, transmitted from the roots of Sow Thistles. It is certain that any one who grows Sow Thistles in his garden is not at all likely to be very successful with choice Alpines. Our plants are now looking remarkably green and healthy, and most of them are well exposed in the frames in an open piece of ground; the lights are left off night and day, but still the plants show autumn trusses. We are not alone in this, as a celebrated grower near Manchester writes to say that his plants are quite as erratic in this respect as ours are. He suggests placing them quite out in the open air all through the summer months—a practice with which I quite agree, but it is necessary always to keep them in the frames, so that the glass lights can be placed over them in rainy weather.

Carnations and Picotees.—Arrangements must now be made to remove all layers and pot them either singly in 3-in. pots or a pair of plants in pots of a larger size. The compost that seems to answer best is four parts good sweet maiden loam, one part leaf-mould, and one part sharp sand. We were very late in getting the Carnations layered this year, but the plants so far are looking quite as well as we ever had them. The leaves are deep green and healthy, not a spot of disease being visible anywhere. When the plants are potted, place them at once in a cold frame, water with a fine-rosed watering pot, and then place the lights over them, keeping them rather close and shaded for a week until they have formed fresh roots.

Dahlias.—Those who were desponding a few weeks ago about the quality of the Dahlia bloom may now have had reason to change their mind. The plants are healthy and producing well-formed flowers in abundance. The nights are much warmer than they were two or three weeks ago, and the days are fine. The blooms should still be thinned out, and the stems should be tied to the sticks as they advance in growth, as the plants are very heavy and easily injured by winds. Shade the flowers, especially the light-coloured and pink ones, and see that the ground is kept stirred with the hoe.

Gladioli.—We are now getting some good spikes of these. It is, however, too late to fertilise the blossoms for seed saving, as the seeds would not have time to ripen. The ground between the rows should be well stirred with a hoe, or if it is wet, the surface may be lightly forked over, in order that there may be a good opportunity for the bulbs to ripen. It is not likely that they can ripen well when the soil is, as I have often seen it, trodden hard between the rows, the surface quite wet and in places covered with a growth of green *Conferva*.

Pinks.—If pipings of these have done well, now is the right time to prepare a bed in which to plant them. When a Pink is lifted out of the ground it does not seem as if the roots run far from the main stem, but they do. They run well into the ground, and it is best to trench the beds 2 ft. deep, working into them some good rotted stable manure, some of it at the bottom of the trench, and some of it 6 in. under the surface.

Tulips.—If the ground intended for these has been cleared from other plants the beds may be prepared at once if time can be spared for that purpose. Growers who make a speciality of them take infinite pains to prepare the beds well, excavating the soil to a considerable depth, and then filling the space with good loam mixed with rotten manure. Those who cannot afford this would do well to trench the ground to a considerable depth and manure it well; then at planting time they should place about 6 in. of rotten, chopped-up turfy loam on the surface, and in that plant the bulbs with a little sand under and over them.

J. DOUGLAS.

Extracts from my Diary.—September 23 to October 1.

VEGETABLES.—Planting out large quantities of Daniel's Defiance and Cocoa-nut Cabbages for spring use. Hoeing ground between crops of Endive and winter Lettuce. Tying and training Cucumbers. Manuring a south border, and preparing it for trenching. Cutting all self-protecting Broccoli fit for use. Sowing Osborn's forcing French Beans. Earthing up Celery when the weather is dry. Tying, stopping, and training winter Cucumbers. Sorting Potatoes, and picking out diseased tubers. Digging ground on which has been Gherkins, and manuring it for Cauliflowers. Thinning out Lettuces sown on borders, leaving some for hearting. Cutting all self-protecting Broccoli and ripe Tomatoes. Trenching border for Cauliflowers. Tying and stopping Tomatoes growing in Pine stove.

FRUIT.—Gathering Dutch Codlin, Wyken Pippin, Scarlet Nonpareil, Dumelow's Seedling, and Bess Pool Apples. Cutting out laterals and surplus wood from Hamburgh Vines to admit light to ripen the wood. Gathering Burreé Diel, Vicar of Winkfield, Duchesse

d'Angoulême, and Gansel's Bergamot Pears. Also Louise Bonne of Jersey and Passe Colmar Pears. Weeding between Strawberries.

FLOWERS.—Getting Chrysanthemums, Carnations, and Mignonette into cold houses. Getting soft-wooded Heaths, Camellias, Azaleas, and Eupatoriums into cold houses from outside. Potting Hyacinths, Crocuses, Tulips, and Snowdrops. Staking out Eupatorium odoratum. Potting old plants of Vesta, Happy thought, Stag's Horn, Crystal Palace Gem, and Hiever Pelargoniums; also *Iris reticulata*. Potting clumps of *Spiraea japonica* for forcing.

PROPAGATING.

RAISING FERNS FROM SPORES.

THE method of propagating Ferns from spores is now so generally known that simple details of the mode of procedure are all but unnecessary. Only a comparatively few years back the cultivation of these plants was far less general than it now is, and by many they were supposed to be difficult to grow, yet such is by no means the case, for if their wants are attended to, they are in reality amongst the easiest to manage of all plants cultivated under glass. It is well known that many species reproduce themselves almost like weeds, coming up by thousands on any moisture-holding material the spores may happen to fall upon, which remains undisturbed long enough for them to vegetate. With these there is no difficulty, as such as are required can be taken up and potted when large enough; but there are large numbers of the most highly-prized Ferns that very rarely increase in this way at all, some defying the attempts of those who undertake their propagation by sowing the spores. For instance, amongst the *Platycterium* *P. grande* and *P. Stemmaria* remain scarce and high-priced, from the fact that not many succeed in raising them, whilst a few manage to so increase them by hundreds. Why there should be so great a difference in this matter relating to the different species of Ferns, a difference much more marked than in most other families of cultivated plants, is a problem I have never been able to solve, nor met with any one who could do more than conjecture the cause; but so it is; if you prepare a seed bed around and beneath where many of these more-difficult-to-raise species are placed, and on which the falling spores cannot fail to alight, it rarely happens that any success attends the operation, even when the prepared medium is treated as to moisture and other essentials, just as it would be if the spores had been gathered and sown. This I have repeatedly proved when the utmost care was taken that no water reached the surface of the seed bed that could wash the small germs too deep down in the soil for them to vegetate.

In addition to the species of *Platycterium* I have named, there are many other Ferns that are equally little disposed to increase from spores that have been allowed to fall from the plants of their own accord; amongst these may be named all the species of the much-prized *Gleichenias*, the dwarf tree species, *Brainea insignis*, *Lomaria cycadiaefolia*, *L. zamiaefolia*, most of the *Davallias*, several of the *Nothocleas* and *Cheilanthes*, particularly the handsome *C. dealbata* (by some better known as *Cassebeera farinosa*), *Angiopteris*, some *Lygodiums*, and other low-growing species and of the larger Tree Ferns, most of the *Alsophilas*, *Cibotiums*, and *Cyatheas*; whilst in the *Dicksonias*, many come so freely that even the base of the stems frequently get studded with young, self-sown seedlings. It needs some experience to detect the right time for gathering the spores with a view to sowing them, and where failure follows it almost always happens that the securing of the spores has been delayed too long, when the seed germs have in reality fallen, and nothing remains but the brown covering or seed vessels. The spores, I may say, of most Ferns are so small as to be scarcely detectible by the naked eye. It is well known amongst Fern raisers that the spores when gathered at the right time will retain their vitality for years, but, like the seeds of most plants, they keep best when not shaken out, that is, when the fronds that have produced them are gathered and dried with the spores attached. The young fertile fronds in the early stages of their development, show the sori—that is, the patch-like cases of fructification that contain the spores, which cases, when the spores are matured, burst and allow the fine dust-like bodies to fall out. It is just when the commencement of this ripening process has been arrived at that the spores should be secured. In the strong-growing species the right condition may be detected with the naked eye; in the case of the weak growers with very small sori, as soon as ever the coverings show that they are beginning to burst, there should be no further delay in gathering. They may be scraped off with a knife on to a sheet of paper, the best way with such kinds as *Platycterium grande*; in the case of species that admit of the fronds or a portion of them being taken off altogether this can be done, and they may be either sown at once or dried gently and then sown. I have

never found much difference in the result whichever course was followed; when dried the fronds can be rubbed in pieces between the hands; if just taken off the plants, they should be chopped into small bits with a pair of scissors and scattered on the surface of the soil in the pots or pans prepared for sowing.

From the necessity of keeping the material on which the spores are dispersed moist, almost up to saturation, it is requisite that it should be of a very open porous character, otherwise it gets covered with green mould before the young seedlings are large enough to remove, and endangers their being smothered. Nothing that I have found is better than ordinary peat broken tolerably fine with some sand and about one-fourth of sandstone broken into bits about the size of Broad Beans mixed with it, giving the surface a good watering first, and pressing it firm, so as to close up all the inequalities, which will prevent the spores getting too deep down in the soil to allow them to vegetate. For the same reason it is well to avoid applying water on the surface, instead of which the pots should be placed in saucers containing a little water, which will be soaked up and keep the material quite wet. The broken up fronds containing the spores should be pressed down close to the soil. Some growers put sheets of glass over the tops of the pots until the young plants make their appearance; but when these are used, I have sometimes found the soil get affected with green mould. Nothing further is needed, except to prick off the seedlings into pots of prepared soil as soon as they are large enough, and later on, when sufficiently grown to put them into small pots singly; but on no account over-pot them.

T. BAINES.

LEUCOPOGON CUNNINGHAMI.

THIS beautiful greenhouse shrub is best increased by means of cuttings put in in the months of May and June. After it has done flowering, cut off the old flower shoots, and place them in a moist growing atmosphere about 60°, when several growths will begin to start; take these off as shown in the annexed illustration, prepare

Cutting of *Leucopogon Cunninghami*.

well drained 6-in. pots by filling them with finely sifted soil, composed of peat, loam, and sand in equal parts, to within a $\frac{1}{4}$ in. of the rim; press this compost down rather firmly. Then put sand on the top, sprinkle with water, and insert the cuttings firmly. Place a bell-glass over them to exclude air, and take care to wipe the glass dry every other morning. Set them on a cool bottom in the propagating house for two or three weeks till they begin to callus, when they may be placed on a slight bottom heat, and they will emit roots in about two months. Give air gradually by tilting the glasses, and they will be ready for potting off and placing on a shelf in a warm greenhouse about the middle of September.

H. H.

Propagation of Lapagerias.—When plants are described as having so many shoots, and their habit of growth is to produce their shoots from underground, as Lapagerias do, people naturally imagine that those who describe them expect to be literally understood. The explanation of "J. S. W." (p. 263) now shows what he means by shoots of the Lapagerias of which he spoke, and simply reduces them to what is usually met with, and if "J. S. W." happens to be in this neighbourhood I can show him plenty. Instead of counting each little side shoot as "J. S. W." now admits he does, most people would call the whole of what each growth from the bottom is composed,

one branched shoot. I have grown these plants long enough myself, and have seen sufficient of what the largest and most successful growers in the kingdom have been able to accomplish to be able to judge pretty correctly what can be done with them; and this further explanation given by "J. S. W." proves clearly that in discrediting the age and size of the plants, as first stated, I was correct. But this is of less importance than the propagation of Lapagerias, which most people would be glad to increase as fast as they do Vines or other easily-struck plants, and when "J. S. W." wrote about striking them from eyes as readily as Vines, I was in hopes that he had hit upon some quick method of which he would give further details that would enable others to do likewise, but this he has not done.—T. BAINES.

Marechal Niel.—Recent experience leads me to conclude that summer is the best season for propagating this Rose by means of cuttings. These, if taken from the blooming wood in spring after the flowers have been gathered and put in under a handlight and kept shaded, or indeed anywhere where they can be kept moist and protected from the sun, will strike freely. In this way eighteen out of every twenty will root. If this plan were generally adopted, Marechal Niel might soon become as abundant as the commonest Rose in cultivation. The cuttings should not have more than two buds above ground.—A. D.

Autumn-struck Fuchsias.—It is not yet too late to propagate any of the varieties of Fuchsia which it may be desirable to increase for next season's display. If potted off into small pots before winter sets in, and kept growing gently in a light airy position and intermediate temperature, they will be healthy little bushes early in spring, fit for potting and growing on quickly if specimens are desired, or for flowering in a small state in medium-sized pots for the decoration of the conservatory, or for general indoor decoration. Any not required for early flowering will do well during the summer months, set out-of-doors in a sheltered position, and kept well supplied with water and weak liquid manure; all blooms should be picked off them closely until within a month of the time when they are required in flower, when they will make a fine autumnal display. Fuchsias possess such a graceful habit of growth, that the less training they get the better; one central stake to support the leader, and pinching any shoot that may be outgrowing its neighbours, are all that is needed, and whether as border plants, single specimens on turf, or as pillar plants or in pots under glass, they are subjects that always well repay any attention that may be bestowed on them.—J. G.

TREES, SHRUBS, AND WOODLANDS.

PLANTING FOREST TREES.

(Continued from p. 259.)

WHERE pitting is the mode of preparation adopted upon clay lands, the longer the interval between the hole digging and the planting the better for the trees. Sufficient time should, in all cases, be given for the chopped turf or surface slice to decay after being placed in the bottom of the pit, as it thus becomes available at once as food for the young plants, and during the process of planting the pulverised soil will insinuate itself under and around the roots. The holes also should be sufficiently large to allow of several inches of the fine soil surrounding the roots on all sides, otherwise many of the plants will languish and perhaps die off at the end of the first or second years for want of proper treatment. The marked superiority of growth which is observable in trees planted upon made ground, where every particle has been moved, and that to a considerable depth, should convince every tree planter of the great advantages of cultivation, and a thorough comminution of the particles of the soil. And here, a word may be said against the very common practice of stamping into the holes a mass of wet clay, thus forcing all the roots to the bottom, and both covering them and surrounding them with a substance quite impenetrable to the rootlets.

The practices of planting indiscriminately all kinds of forest trees and distributing them throughout the plantations with the regularity of the patterns upon a wall paper, are at once opposed to science and to correct taste. Few foresters can boast of soils adapted to the growth of any great number of species in the same enclosure, and the recurrence of the same forms and tints in spring, summer, and autumn at regular intervals throughout the woodlands, entirely destroys the spirit of planting. It may often be advisable to mix up the deep and shallow-rooting trees, so that the soil may be well occupied from its surface downwards. Besides, some of those trees whose roots penetrate the deepest bring up to the surface and scatter over the land by their fall of leaves, substances beneficial to other trees whose roots do not descend deep enough to reach them. These substances have also a beneficial effect upon the herbage which

springs up after the land is either partially or entirely cleared of timber. Though little or nothing will grow under the shade of a dense Ash, yet after the clearance of the timber the land is undoubtedly improved, and where a crop of Oaks has been matured, the land is found to be considerably benefited by the saline matter obtained from their leaves, which amounts to about 5 per cent. of their whole weight. After a plantation of Larch has been thinned out sufficiently to allow Grass to cover the ground, such herbage far surpasses both in quantity and quality what the land previously produced.

In plantations intended mainly for profit, grouping according to soil and situation will be found the surest method. It is often asserted that the finest Oak, Ash, Elm, and Beech are to be seen as single specimens in the midst of, or upon the margins of, other plantations. But wherever such an instance occurs the particular tree is generally upon its own soil, and is found to be flourishing at the expense of all around it. An Oak in a deep loamy soil resting upon clay; an Ash or an Elm in a loamy gravel; a Beech upon a calcareous gravel resting upon a bed of chalk; a Scotch Pine at a considerable elevation, and in a gravelly soil which affords it complete drainage; a Horse Chestnut in a deep loam, with a dry bottom, a Mountain Ash in a high situation where it meets with light sandy land; a Birch in a light black loam with a gravelly substratum; and a Spanish Chestnut in a dry loamy soil upon gravel, afford at once the finest specimen trees and the most serviceable timber.

As most large areas of land selected for planting will comprise many varieties of soil and different aspects, it will generally be found advisable to group accordingly. The deeper soils will suit the Oak, Elm, Ash, Walnut, and Chestnuts; the sands and gravels the Larch, Sycamore, Beech, and the Hornbeam and Spanish Chestnut for underwood; the boggy and wet lands the Willow, Alder, and Poplar; and the moist lands the American Plane, the Ash, Lime, and Birch; while the very thin soils will carry the Scotch Pine, the Silver and Spruce Firs, and the Mountain Ash.

Though cultivation proves highly beneficial to young trees by placing within their reach all the available food contained in the soil, and also by actually increasing the amount of such food, too much manuring will often force growth beyond what is advisable for the texture of the wood. It is not the fastest-growing tree that furnishes the best timber, else the Oak of the park would be preferred to that of the forest, and the Larch of the valley to that grown upon the hillside. Cultivation in conjunction with manuring should be practised only upon such trees as are planted in worse than their natural soils. Enough of early cultivation to impart constitution should be bestowed upon all young trees.

The use of nurses in plantations is a subject deserving notice. How seldom do we find these planted sufficiently thick or of adequate strength to give the necessary shelter to the main crop. The extent to which they should be used must depend upon the exposure. Where this is great, they may be filled in to within from 30 in. to 36 in. of the standards and of each other. Upon more sheltered sites they may be from 4 ft. to 6 ft. apart; and when thinned out, they will have attained useful sizes. The Mountain Ash is second only to the Larch for use in bleak situations; and the Spruce will afford a better shelter upon a less space than the Scotch Pine. The Sycamore, Norway Maple, Pinaster, and the Elder are very serviceable near the sea.

The forester who has access to a well stocked home nursery, ought to be able to ensure a certain amount of success in his work, as he can raise his plants when they are required, and replant them in the best possible condition. By dividing his hands into raisers, sorters, carriers, and planters he may get over in a systematic way a large amount of work in a short time. Wherever the trees have to be carried considerable distances, and to remain out of the ground more than a few hours, it is a good practice to puddle the roots by dipping the bundles into a tub containing earth and water mixed to the proper consistency. All root-pruning should at this time be avoided, beyond cutting off the extremities of such as are injured in the getting up. Nor should the pruning of side branches be now attempted, except so far as it may be necessary to foreshorten straggling growths, or to reduce such heads as are quite disproportioned to the strength of the roots. The wounds caused by close side pruning at the time of transplanting are slow in healing over, on account of the deficient circulation of the sap during the first season. For this reason the trees intended for removal should be pruned in the nursery any time about June or July.

Though the early autumn is strongly recommended as the best time to ensure success, where the operations are large, the work may have to be carried on during all the available weather between the early part of October and the end of April or the beginning of May. Indeed there are few weeks in the whole year when transplanting of some kind may not be taken in hand. Frosty weather

should be avoided; but when hard pushed the planter may otherwise work throughout the winter, especially if he selects his land with an open bottom for the early autumn and the wetter parts of the winter, reserving cold bottomed and heavy retentive lands for the spring. Very wet lands should never be planted late in the winter, unless in exceptionally dry weather, and when they have received a good previous preparation.

The length of time which it takes to rectify mistakes in planting should make the forester doubly careful to ascertain by observation and analysis the capabilities of the land he selects for plantations, as it sometimes takes years to discover and the work of a lifetime to rectify what has been done amiss, and free-growing and flourishing trees even of an inferior kind are far preferable to stunted specimens of the choicest sorts.

A. J. BURROWS.

The Araucaria imbricata in South Germany.—

When recently visiting the to me interesting garden of a distinguished collector of new and rare plants and shrubs in the neighbourhood of Baden-Baden, I was shown with great pride by the proprietor a small but fairly healthy specimen of the above-named well-known Conifer (which in this country is, I believe, perfectly hardy), and informed, to my great surprise, that it was, he believed, the only living specimen of the tree in South Germany. He attributed the fact of its having resisted and survived the winter frosts to the peculiar position in which he had planted it, at the bottom of a kind of deep glen or ravine, where the hill rising steeply immediately on the other side completely sheltering it from the morning sun, which, after severe frosts, had proved fatal to all those exposed to its rays.—W. E. G.

Yellow Fruited Guelder Rose.—Having for many years grown this fine hardy shrub in the south of Ireland without ever succeeding in getting it either to flower, or produce its highly ornamental bunches of bright coloured berries, I availed myself of a visit to the unrivalled collection of my friend, M. A. Lavallée, at Segrez, on Monday last, in order to see this shrub, which was then in full and copious fruit in one of his shrubberies; and on his pointing it out to me I was much surprised to see the berries of a most brilliant scarlet colour, instead of yellow as I expected them to be. M. Lavallée, however, informed me that the first colour they assume in the early autumn is bright golden yellow, which, as the season advances, changes to scarlet, and ends by becoming black as ink before the berries fall off the bush. The birds usually so fond of berries do not seem to touch these at all.—W. E. G.

Catalpa syringæfolia.—This beautiful flowering tree forms at present a conspicuous object in pleasure grounds, being quite covered with flowers that are spotted like those of a Foxglove. Catalpas evidently like full exposure to sunshine and air, as I find that those on the sunny slopes of our hills are much more floriferous than trees in shaded positions. The young wood like that of the Paulownia, which the Catalpa somewhat resembles in habit and style of growth, is soft and liable to injury from severe frosts when in an unripened state, but when fully mature it withstands a considerable amount of frost, and in order to ensure that condition it should be planted on well drained soil, and not grown over luxuriantly. The Paulownia with its singular purple flower spikes was most effective here in spring, and now the Catalpa is even more interesting, owing to the dearth of flowering trees which there is late in summer.—J. GROOM, *Linton*.

Pinus insignis as a Sea-shore Tree.—The great merit of this as a sea-shore tree is well shown at Bodorgan, in Anglesea, where many specimens are in perfect health within a few yards of the sea. There is perhaps nowhere a more wind-tortured district than Anglesea, judging by the appearance of the few stunted native trees that withstand the blast. Planting of the most beautiful kind is, however, established almost on the sea-shore. On the margin of the shore the Sea Buckthorn, Furze, and Darwin's Barberry first meet the south-western gales and almost continual winds. A few paces within these the first plants of *Pinus insignis* and the common evergreen Oak appear, and soon, with the aid of these excellent shore trees, almost any kind of evergreen planting may be carried out. The whole place is most instructive as regards planting near the sea. The contrast between the wind-swept surface of the island and the noble avenue of evergreen trees leading from the entrance lodge to the house is very striking.—V.

Rhus Cotinus.—This Sumach is just now an object of great beauty in the ornamental grounds at Castle Ashby, Northamptonshire. It is doubtless a very old plant which in course of time has grown into a large bush and made a quantity of hard wood. During August it flowered and has since been succeeded by the long feathery flower stalks which, being produced in large pinnacles, have a very charming effect. It is said that in Italy this plant used for tanning purposes.—R. D.

THE TASMANIAN TEA TREE.

(LEPTOSPERMUM LANIGERUM.)

THIS is a very valuable New Holland species, which has of late years been rarely grown and distributed, except by Messrs. McClelland, of Newry, who are tolerably well known as keeping up a stock of rarities in the way of hardy plants "not generally known." In habit of growth this plant closely resembles some Cotoneasters; the leaves are, however, almost silvery in colour, being densely clothed with soft, silky hairs; the young wood is of a pink colour, and the large pure white, Saxifraga-Burseriana-like flowers are produced in the axils of the last year's lateral branchlets. Our sketch merely represents a tiny spray from a branch 15 in. long, which was a Hawthorn-like mass of flowers and leaves. My predecessor here had noted its merit, and a small specimen endured the late severe winter with impunity side by side with *Billardiera longiflora*, *Berberidopsis corallina*, which is now lovely with glossy green leaves and drooping coral-red buds and flowers; *Commelyna cœlestis*, *Benthamia fragifera*, *Oxalids*, and the small *Fuchsia gracilis*. The last-named *Fuchsia* is a lovely plant, never growing above 9 in. or 10 in. in height, and so forming bushes 12 in. or 15 in. in diameter, each slender shoot bearing numerous red and purple flowers and bright coral red buds. My good friend Mr. Hemsley sends me word that it is a "starved form of *F. Riccartoni*," which, indeed, botanically it possibly may be; all I can say is that

Spray of the Tasmanian Tea Tree.

growing in a similar situation on rockwork a few yards away is the true *F. Riccartoni*, 4 ft. or 5 ft. high, with much larger foliage and flowers, which look thin and poor in comparison with those of the dwarf *F. gracilis*. I shall some day send good specimens of both to Mr. Hemsley, who is our best English authority on the genus, and shall then be quite content to abide by his decision. Species or variety, however, matters but little, since all garden-loving amateurs will be glad to possess a form of *F. Riccartoni*, which blooms freely at 9 in. high in compact bush form. How contemptuously the Knight of Kerry would look down on my poor little pet after contemplating his "specimen" of *F. Riccartoni*, which is nearly big enough to fill the temperate house at Kew. To return to the *Leptospermum*, I may mention that small plants in 4½-in. pots are 15 in. to 18 in. in height, and one such for which I paid eighteen pence has just now numerous sprays of its milk-white flowers. For a cold greenhouse in pots, or as a wall shrub in a sheltered position, this distinct Pittosporaceous shrub should be made most welcome.

B.

FORMING AND PLANTING SHRUBBERIES.

IN selecting a site for a house and grounds, where the choice is not limited, there is often a want of judgment and taste displayed in seizing upon and utilising to the utmost any special local features or conformation of ground which may be easily beautified and made pleasant for the eye to rest upon. A group of old Oaks or Elms gives an air of age and grandeur to any place; that is, if the house has anything in keeping with it. A small watercourse meandering through a meadow may be opened out into a miniature lake, or at a less expense be converted into a winding stream garnished with *Water Lilies* and numerous other interesting aquatic plants. It is not necessary or desirable that each place should include everything; on the contrary, it is better to elaborate and work out that special feature which seems natural to it. An elevated site should be selected, if possible, for the purpose of securing an efficient and easily arranged system of drainage, and it permits also of a bolder and more picturesque arrangement of the various groups and belts of trees and shrubs that are necessary for shelter and privacy. All trees of large growth should be planted at a sufficient distance from the house, so as not to obstruct air and light. Even stables and offices, which it may be necessary to shut out with trees or masses of shrubs, should not have anything likely to grow tall planted too near. The falling leaves often block up water-spouts and gutters, and in some unlucky moment, from some trifling oversight, the place may be flooded. Buildings that are exposed to the drip and damp of overhanging trees are far more perishable, and cost more for repairs, than if exposed to the drying influence of air currents. A house or building embowered in trees is a delightful retreat in very hot weather; but it is usually damp in our climate, and generally unhealthy. It does not follow from this that any building, or portion of a building, may not be effectually blinded or hid, if it be desired, without incurring the unpleasant consequences of finding at some future day that the trees employed were unsuitable and must be removed, and the work done over again; and, to avoid all danger of this, the planter should make himself acquainted with the life-history, so to speak, of the numerous families of plants that are available for outdoor decoration. It is impossible for anyone to arrange or group plants or trees properly about whose origin or antecedents he knows little or nothing.

In planting merely for shelter, common, hardy, fast-growing things may be employed. I have seen the *Huntingdon Elm* used in very exposed places, to receive the first fierce blast of the wind, with good effect; and it grows rapidly, and has a less stiff and more elegant appearance than the common *Elm* or *Oak*. Having established a first line as a sort of outwork against the enemy, better and choicer trees and shrubs may be introduced. There are, of course, places where these observations on the importance of shelter are unnecessary. The greatest amount of shelter will commonly be required on the north and east aspect, though there are localities where the west winds at times come with the force of a hurricane. They are usually not so cold and cutting as those from the east or north; still, it is necessary to provide shelter in some situations against their destructive force. In the arrangement of the groups of trees and shrubs many things have to be thought of before the plan is laid down. The means of the proprietor will in the main decide the question as to the quality of the materials employed. The outside furniture of a residence is just as much a matter of expense as the furniture for the interior; and it reflects in the same way the proprietor's tastes and means. And as planting, either for shelter or general effect, may be looked upon as a permanent work, it is a great pity to do it imperfectly, either by deficient preparation of the sites, or by planting cheap and inferior subjects. If the work be well done, and a good selection suitable for each position made, it will annually become more valuable and interesting. One of the evils to be avoided is thick planting; many shrubberies are utterly ruined by that, and subsequent neglect. Thick planting would do no harm if thinning were attended to in good time; but even then I question the advantage of planting many masses, except it be on the windward side. Besides, buying more plants than are really necessary adds to the cost of the work. Many annual plants of vigorous growth might be used to furnish thin places in newly planted shrubberies for a few years till the permanent plants were established and beginning to cover the ground; for this purpose *Castor-oil* plants, giant hemp, and other similar plants, may be used in the middle of the groups, with dwarf annuals towards the outside.

In setting out positions for belts or groups of trees and shrubs in bleak, exposed situations, where the soil is bad or inferior after the positions are marked out, and trenched soil should, if possible, be carted from other positions and placed on the top to deepen its staple; it will elevate the site and give the planter an earlier opportunity of seeing and assisting the development of his ideas than would be possible if planted on the level. The idea of planting on slightly elevated sites may perhaps be cavilled at and deprecated; but the extra

***Pavia macrostachya*.**—This at present forms a fine feature in the ornamental grounds at Castle Ashby. It is 14 ft. or so in height, over 30 ft. through, and one mass of blossom down to the very ground. The blossoms are arranged in tall spikes; they have long projecting stamens, and they are also fragrant. The leaves are produced on long petioles, occasionally flattened out in a peculiar manner. This species is also known as the Edible Buckeye (*Pavia edulis*) in America, on account of the fruit being eaten either boiled or roasted. It is a very fine deciduous tree, and one that should be planted much more frequently than it appears to be. *Pavia parviflora* and *P. spicata* are said to be identical with the foregoing.—R. D.

***Hypericum oblongifolium*.**—I noticed this handsome large-flowering kind, with polished golden buds, in bloom at Glasnevin. It is, no doubt, obtainable in the London nurseries, and deserves to be generally planted as a valuable autumn-flowering shrub.—V.

depth of soil obtained, and the freer drainage which is secured, add so much to the warmth of the soil, that many rare plants may be planted with a reasonable prospect of their succeeding, even in otherwise impossible situations, and which it would be almost hopeless to think of planting unless some such plan be adopted. Every experienced planter knows that a plant about whose hardiness there may be any doubt often succeeds on a raised site, when others in a lower situation fail. But I do not believe in raising the site at the expense of depth of soil. The elevated surface should be so much added to its depth—not, as I have sometimes known to be done, raising the surface by filling up underneath with stones, or clay, or rubbish. I am inclined to think, from what I have seen, that much mischief has been done by planting what ought to be permanent subjects on mounds of stones; in dry seasons the plants actually perished for want of water. Trees planted on a heap of stones are in a worse position than if growing in a thin stratum of soil on the natural rock, so far as regards moisture. It may savour somewhat of empiricism to attempt to lay down rules or to give hints about a matter requiring a special study of all the connecting circumstance, many of which would be altogether of a local nature. These should, and must be thought out on the spot; but when the ideas have been matured, and the plan arranged, if the designer takes hold of one end of an ordinary waggon rope, steps out boldly with the rope trailing behind him, with a couple of men each provided with an armful of pointed stumps to stick in the ground, at short intervals, by the side of the rope as it glides along, it will be found that a bolder, freer, better outline has been obtained in a few minutes than perhaps would or could be secured by trusting to the eye or by measurement. I have seen both plans tried, and the rope plan is by far the best, always supposing the person drawing the rope possesses a good eye, and has the design well arranged in his head. In making alterations involving earth-moving—which most improvements do—there should be no difficulty in arranging for the improvement and deepening of the soil where the better and choicer kinds of trees and shrubs are intended to be planted. The next two or three months is the best time for making alterations or improvements involving new groundwork, as well as for planting all kinds of trees and shrubs. I hope, in a future paper, to say something about the selection of trees and shrubs and their planting.

E. HODDAY.

THE KITCHEN GARDEN.

ASPARAGUS CULTURE.

(Continued from p. 250.)

Growing Early Asparagus in the Open Ground.—

Asparagus may be brought to perfection fifteen or twenty days before the usual time by adopting the following system: A border is prepared along a wall having a southern aspect and a sheltered position. A trench is dug all along the length of the wall to the depth of 14 in., and filled up with a mixture of two-thirds of well rotted stable manure and one-third of the soil taken out of the trench. The compost having been thoroughly incorporated, about 6½ in. to 7¼ in. in depth of the earth on the near side of the trench is thrown up to form a mound sloping to the south against the wall, so as to have the soil near the wall some 7 in. to 8 in. above the level, and that near the pathway 6 in. or 7 in. below it. The mound being thus prepared we plant our stools of Asparagus at a distance of about 13 in. from each other, and at about 2½ in. from the wall. The second row is likewise planted at a distance so as to have four rows of plants on a mound of 3 ft. in width. The stools being planted, they are covered up with well rotted stable manure to the depth of about 7 in., so that the mound commences at the level of the pathway, rising gradually until it reaches the height of 16 in. above the level at the spot where it joins the wall. For such a plantation we ought to use the early pink *Argenteuil* variety of the best quality if we wish to obtain good results. Any other variety will produce nothing but unsatisfactory crops both as to quantity, quality, and duration. This plantation must have the same attention paid to it as the others already described, in addition to which it must be watered during the summer of the first year if it is a very dry one. At the end of three years we may begin to gather in the crop. For

this purpose the border is covered in the month of February with some good dry stable litter. If fine weather sets in early, especially if it is sunny, the litter should be cleared away and restored once more to its place as soon as the evening approaches and the temperature becomes lower. As long as the weather remains cold, the border must be kept well covered with the litter. As soon as the Asparagus heads begin to show aboveground, the litter must be taken away entirely for fear it should communicate a bad taste to the Asparagus, and be replaced by straw mats, which are taken away on fine days, and replaced as soon as the evening sets in. Asparagus plants grown in this fashion yields a crop from a fortnight to three weeks earlier than they otherwise would; we must therefore stop gathering them at least three weeks earlier than in the case of Asparagus grown in the usual manner.

Forcing Asparagus.—In order to force Asparagus to produce a crop early enough to be quite out of season, it may be grown either in the open ground or in heat. If for ordinary cultivation we ought to select the best varieties to be obtained, we ought to be still more careful in choosing our plants when we are going to force them. The strongest and healthiest-looking plants should be chosen for this purpose.

Forcing in the Open Ground.—Beds are prepared in the ordinary way of 3¼ ft. in width with a distance between them of from 2 ft. 2 in. to 2 ft. 4 in., the stools being planted about 1 ft. 1 in. apart in every direction, so that there are three longitudinal rows of plants in each bed, the outer rows being about 6½ in. from the edge of the bed. The same care is bestowed on these plantations as on others, and when the third winter comes, we may begin to force the Asparagus planted in this manner. For this purpose, towards the end of October or the beginning of November, we dig out the soil forming the pathways between the beds to the depth of about 1 ft. 8 in., the trench itself being about 2 ft. 4 in. in width. In digging out these trenches we throw out sufficient soil to cover the stools to the depth of about 1 ft., in order that the forced heads may be of a good length, and may remain white. This done, we fill up the trenches with good fresh stable manure, beating it down evenly, after which we cover the beds with as many frames, with their accompanying lights, as they will hold to keep up the heat of the beds. The frames should be about 6 in. or 7 in. apart. If we place any stable manure inside the frames, it must be taken out fifteen days after it has been put in for reasons before explained. Every evening towards sunset straw mats are thrown over the frames to prevent chilling. If the cold is persistent, or increases in severity, the straw mats should be doubled, and if it be very intense we may even fill up the spaces between the frames with warm stable litter, and do the same with the trenches between the rows. Asparagus treated in this fashion begins to show above the soil in from twelve to fifteen days, according to the heat to which the beds have been subjected. If the weather is very cold, they will take a much longer time in making their appearance. In the latter case we must redouble the precautions we have taken to keep in the heat, heaping on stable manure with a lavish hand, stopping up every nook and cranny in the frames and preventing the snow from melting on them. By this means we obtain perfectly white heads, but if we wish to have them tinged with pink we must take off the straw mats whenever the sun is warm and clear, and we shall find that they will be rapidly coloured by the action of the light. The heads should be cut every other day, and the cutting may be kept up for a couple of months. The following winter, the manure surrounding the frames and in the trenches is taken away,

and the plantation is allowed to rest quiet until the second winter, when the same operations may be gone through. We may thus continue to force every other winter until the quality and quantity of the Asparagus show signs of lowering. In the spring which follows the winter during which the forcing has taken place, we must, of course, refrain from gathering, otherwise we shall endanger the future safety of the beds. Forcing every other winter is as much as the plants will bear. In order to be able to force every winter, we should have two or four plantations, one or two of which should be used for the purpose turn-and-turn-about. As each bed ought only to be used for two months, a quadruple set is advisable, so that we may be kept supplied during November, December, January, and February.

Forcing in Heat.—The Asparagus grown in heat is known as green Asparagus, and is eaten with white sauce or as a garnishing with green Peas. This method of forcing is carried on from the month of November until the month of March. Each bed only yields for a month. A hotbed is made in the usual way and is covered with 2½ in. or 3½ in. of rotten manure, after which the frame and lights are placed in position. When it has cooled down sufficiently, that is to say, in about eight or nine days, the stools are planted. The plants chosen for forcing ought to be three years old, well grown, and provided with a full allowance of roots. The roots must be gathered together and their extreme ends clipped. The stools are then placed in the bed in such a way that they may touch and support each other. They are so arranged that their heads are all level. Rotten manure is then thrown in between the roots, leaving the eyes uncovered, and the lights and frame are so arranged that the heads will find sufficient room between the bed and the glass to grow to their proper length without being bent. Under an ordinary light we may thus plant four or five stools, each of which will begin to yield at the end of ten days or a fortnight, and will last a month. This mode of cultivation produces very small and short Asparagus, and it does not possess the fine flavour of the other kind. These beds want a good deal of looking after to avoid all danger of chilling. Fresh manure must be added immediately the heat begins to decrease. The frames must be kept carefully closed, and the straw mats must be taken away and replaced according to the state of the weather. This method of forcing, like the preceding, may be commenced in October and November, and by using several sets of beds, may be carried on during December, January, and February. Some growers have attempted to force old Asparagus plants, but they soon had to give it up, owing to its yielding such bad results. We are consequently obliged to fall back on the young plants brought up in the nursery for this special purpose; it is, in fact the only way to obtain good and abundant crops.

THE ENEMIES OF THE ASPARAGUS.

The principal enemies of the Asparagus are the Asparagus beetle (*Crioceris asparagi*) and the white worm or grub of the cockchafer.

Crioceris asparagi is a small beetle, long in the body, and of a red colour, speckled with grey and white spots. The larvæ are somewhat cylindrical, narrower towards the head, and are of a dirty olive-green colour, fleshy and shining. It only lasts in the larva state for about ten days, but during that time it commits the most formidable ravages. It deposits its eggs on the tenderest parts of the Asparagus, which are speedily attacked by the young larva as soon as it comes out of the egg. These destructive insects will devour a whole plantation in a brief space of time if their ravages are not checked immediately they are perceived. Incessant war must

be made against both beetle and larva. If there are only a few they may be crushed between the finger and thumb. They must especially be looked for during bright sunshine, which is the time they generally make their appearance. If they are too many to be destroyed in this way, we must take a bowl or other vessel full of water, and holding it under the Asparagus, tap the stems lightly, so as to shake off the insects into the water. As soon as they feel the blow their instinct teaches them to imitate death and drop off the shoot. When all have been caught the water may be thrown on the ground and the insects crushed to death with the foot; or, what is better still, the cold water should be strained off and boiling water poured on them. The Asparagus beetle lays twice a year—in the spring and in June or July.

The Mole.—The mole does not feed on the Asparagus plant, but it damages the roots by displacing them in forming its subterranean galleries, generally laying the roots bare by lifting them above the soil. The presence of the mole is easily discovered, and as soon as it is perceived, immediate measures for its destruction must be taken. We must either use mole traps, or else watch for its appearance hoe or spade in hand, so as to dig it out the moment it is seen lifting the surface of the soil.

The White Worm.—The white worm or cockchafer grub is one of the most dangerous enemies with which the gardener has to deal. The warmer the weather the better its appetite. If you see an Asparagus plant beginning to look withered without any known or apparent cause, gently turn up the soil at the foot of the stool, and the chances are that you will find a cockchafer grub feeding on the tenderest parts of the root. There is only one way to destroy it effectually, and that is to dig for it and crush the life out of it with your foot. Lime, sulphur, and other insect poisons have apparently no effect on it. Some growers sow Lettuces, in order to attract the cockchafer grub from the Asparagus, but the remedy is worse than the disease, for these pests flock into the Asparagus plantations from all parts of the garden, and attack the Asparagus as well as the Lettuces. GODEFROY-LEBŒUF.

THE POTATO DISEASE.

CONFIDENT as Major Hallet may appear to be in the efficacy of his "selection" plan for stamping out the Potato disease, I fear that he will find but few who will be as satisfied as he is as to the results. "J. S. W.," thinks the matter worthy of further enquiry, and so it may be, but all experience so far points to the conclusion that it has no sound basis. I should like to have exact answers to the following questions from Major Hallet. 1st. What were the sorts of Potatoes to which he makes reference? 2nd. Did or did not the haulm show the spot and die off as other Potato haulm has done? Or 3rd. Did he lift all his Potatoes before the disease appeared! 4th. At what date did he lift his stocks? And 5th. Since he lifted, what proportion have gone diseased? Now, with reference to the first question I may say that I have lifted some kinds that, at the time of lifting, did not show a single diseased tuber, but some have shown it since; therefore, at the time of lifting, I might have asserted as much as Major Hallet has done, without reference to selection at all. 2nd. I might have lifted every tuber before the disease appeared, and thus perhaps saved every one sound, but they would have been small and unripe, and this also includes the third question, and as to the last one I may say with the melancholy Jaques "Thereby hangs a tale." Now, if Major Hallet's Potato plants lost their foliage, even as others did, and yet not a tuber, as he asserts, was diseased, then stamping the disease out is wholly out of the question. In such a case any escape in the part of the tubers must be due to soil or some other cause. The Potato disease has not been known to us more than thirty-five years, and there is no evidence beyond that of mere assumption that before that time any exact symptoms of it were visible. It came and found the plant in a healthy and robust state, just the food upon which it loved to exist, and from that time to this, it has come in the atmosphere just as cholera would come and strike down even the strongest and most

robust. With the present race of Potatoes as they now exist there is no hope of counteracting it, but if we can produce altogether a new race that shall have the leaves and stems entirely impervious to the minute and destructive spores of the fungus, then we shall accomplish far more than Major Hallett will do in a hundred lifetimes of selection. As far as we yet understand the Potato fungus, it is wafted by the moving atmosphere, alights upon the foliage of the Potato plant, and, finding the required moisture to induce growth, it sends forth its minute mycelium, which enters into the internal economy of the plant, bursting and destroying the cells and the cellular tissue in its progress, and penetrating finally into the newly formed tubers more or less, just as the nature of the plant stems, or rather the woodiness of the cellular tissue may present obstacles to its progress. It is thus that plants grown in rich soil where the growth is sappy and soft, and the tissue thin and watery always are worse diseased than are those grown in poor soil; and without doubt it is for this very reason that *Mamum Bonum*, a kind that has the hardest and woodiest of stems, exhibits so little disease. It is idle to talk about hereditary tendency, inasmuch as up to the moment of the first appearance of the fungus there is not the slightest reason to suppose that there is the least taint of disease in the plant.

A. D.

Centennial Potato.—Results exactly identical with those experienced by "K." (p. 267) followed from planting this Potato in my case; only three came up out of fifty sets. This freak has before occurred to some others of the American sorts, and it is a difficult matter to explain, except on the assumption that the tubers had been during the winter sufficiently exposed to the frost to cause blindness without softening the flesh of the tubers. I quite think that such was the cause of the peculiarity in my own case, but if others were to show the same results as had befallen me, then I must, of course, conclude that some other cause must be looked for. In my experience I have never found any Potato to repeat this feature in successive years.—A. D.

Cucumber Sir Garnet Wolseley.—At a recent meeting of the Border Counties Horticultural Society, held at Carlisle, Messrs. Joseph Hamilton & Son exhibited a large collection of Cucumbers, amongst which I noticed a brace named Sir Garnet Wolseley, which struck me as being the handsomest Cucumber that I have yet seen. I also noted that the brace shown grew from the same joint, and that they were "as like as two Peas." If the flavour of this Cucumber corresponds with its handsome shape and its apparent prolificness, it will become a favourite.—A CUMBRIAN GARDENER.

THE LATE MR. WILSON SAUNDERS.

HAVING read your obituary notice respecting my old friend Mr. William Wilson Saunders, I think that some of your readers might like a few more particulars respecting so eminent and scientific a horticulturist. Mr. Saunders was the son of Dr. Jas. Saunders, Vicar of Kirtlington, Oxfordshire; he went out as an officer in the Engineers to India, and before long returned, married, and settled in Wandsworth, where he began his well known collections. As he had two relatives near, named William Saunders, he obtained his old friend my father's permission to adopt the name of Wilson; he was afterwards generally known as Wilson Saunders. After some years he removed to Reigate where his place became world famous for its garden, plant houses, and scientific collections. Many horticulturists will remember delightful days spent at Hillfield, where much was to be learned from the collection of hardy plants, many of them very rare, and all through the scientific care of himself and of his able gardener, Mr. Green, now at Pendell Court, models of health. His plant houses and frames were full of plant treasures. His great botanical and general knowledge gave him advantages in cultivation such as fall to the lot of few. His long and devoted services to the Royal Horticultural Society are well known; he was Chairman of the Council at the eventful time when the proposal of the Commissioners made by General Scott gave the power of securing the position both of the Society and of the debutante holders. Though at the time having many anxieties of his own, Mr. Saunders keenly felt the rejection by the General Meeting of so desirable an end to our troubles. At the Exhibition of 1851 Mr. Saunders showed a very remarkable collection of different woods, which excited great interest. I might go on describing his worth as an entomologist, and in the Linnean and other Societies, but had better confine myself to the work which comes most within the province of THE GARDEN. Botanists and horticulturists, English and foreign, will long hold in esteemed memory the name of W. Wilson Saunders.

Heatherbank, Weybridge Heath.

GEORGE F. WILSON.

MILDEW AND OTHER FUNGI.

THE life history, and conditions required to be present for the development of the various moulds, is a very interesting as well as an important study for the consideration of cultivators of plants, whether these happen to be of a decorative character or important as articles of food. One thing evident is that some of these blighting moulds, which stand out prominently as the most disastrous in their effects, need for their growth atmospheric conditions completely different from those wanted by others. The more the subject is studied, the more it becomes evident that the germs of these parasites are constantly existent, and only lay dormant until the atmospheric conditions requisite for their active growth happen to be present.

To admit of mildew being injurious one at least of two things must exist; first, the presence of the fungus in an active state, with in some cases a second condition, that is of the plants upon which it preys being in a state that predisposes them to its attacks. In dry seasons when through absence of enough of moisture at the roots the growth of Peas and Roses is weak and languid, then it is that they are most affected by mildew, at once leading to the supposition that the attacks are attributable to the weakened state of the plants. Even the least observant in such matters are now aware that the *Peronospora*, or Potato blight, needs a moist close condition of the atmosphere to favour its growth, whilst the Rose and Pea mildew spread and luxuriate under the opposite conditions of a dry soil and correspondingly dry air. The Potato fungus invariably makes its attacks when the weather has been of a character such as to promote strong active growth in the Potato, not when weak and languid, a difference completely opposite and at once pointing to a remedy so far as regards Peas and Roses, by supplying them with sufficient moisture in dry summers; this has been generally acknowledged so far as regards Peas, but not sufficiently so in the case of Roses. I have noticed the comparative absence of mildew on Roses this summer when growing in open situations where their roots were fully exposed to the rains, as also its presence in considerable quantities where the plants were upon walls and their roots to a great extent out of the reach of the rain, affording evidence that, although the mildew which preys upon them is in a living active condition, yet if the plants are moist enough at the roots they can resist its attacks. The Vine mildew appears to be very different from each of the foregoing, the conditions that favour its spreading to any great extent seeming to be a damp atmosphere and low temperature combined, and I have reason to think that where the opposite of these is maintained it cannot make much progress. In several places Vines have come under my charge that had previously been managed so as to come on slowly and ripen their crop late, but which were so affected with mildew as to make their fruit all but useless, yet when treated to more warmth by early closing in bright weather with less atmospheric moisture and a little fire when it was cold and damp, the mildew never did more than appear slightly towards the end of summer on a few laterals that were left, and in the course of an additional year or two it disappeared altogether, nothing being done to the Vines beyond the usual winter dressing.

T. BAINES.

The Gooseberry Gourd (*Cucumis Grossularia*).—This miniature fruited Gourd is a pretty object when trained to a pillar as it is in the Water Lily house at Kew, where it is now very attractive. It has leaves similar to those of the common Bryony. The fruits are about the size of a moderate-sized Gooseberry, globular in form, and studded with numerous short prickles. In their present stage the fruits are green, and furnished with silvery, longitudinal bands; but later in the season they assume a golden-yellow hue, when they are even more attractive. Its pretty congener the *Bryonopsis laciniata* is a suitable plant to associate with it, as they perfect their fruits about the same period and thrive in the same temperature, which is that of a warm greenhouse. The house should be kept moderately moist during the summer months.—W. G.

"Improvement" of Stephen's Green.—Allow me to thank Mr. Smith, of Newry, for his much needed exposure of the stupid planting in Stephen's Green, Dublin, once a fine open square. Nothing is more sad to see than what is often done in gardens under the name of "improvement." Would Mr. Smith kindly tell us what he thinks of the landscape changes in the same garden? Once one could see a fine sweep of green lawn, but in passing the other day I saw no more of this. At one point I saw from the outside a massive looking bridge, suggesting some expensive cutting up of the once fine free surface into some puerilities such as duck ponds and formal ditches. I had not time to go in and see for myself, and therefore I should be glad if Mr. Smith would tell us what has been done. How hard it seems to teach the lesson that we ought to preserve, not destroy, the freedom and breadth of our garden lawns.—H. T.

WALKS AND FOOTPATHS.

It might not be justifiable to make a distinction between a walk and a footpath as a feature of utility in the garden, still we think there is or ought to be some distinctive difference, in so far as the construction is concerned, between say the walks of a kitchen-garden which have to withstand the wear and tear of traffic, and the footpaths in a pleasure-ground which are made to be comfortably walked on and enjoyed. Some walks must be made to be wear-resisting as well as for comfort; others for comfort alone. The perfection of a footpath is one made of grassy turf, tough and dry, and closely shaven; the perfection of a walk is perhaps one made of asphalt, and peppered over with very fine gravel; but as neither of these perfections is always practicable, or possible, or even permissible, the best attainable must content us. It is remarkable that people will decidedly walk on grass in preference to the smoothest and best kept-walks, so that by the side of a frequented walk there will always be found more or less of a footpath running parallel, unless some obstruction is placed in the way; hence people in every public garden are requested to keep off the grass, an injunction repugnant to their inclinations. It will be remarked that the footpaths or portions of footpaths least avoided are those which are soft and elastic without being wet—the foot at once responds to the soft comfortable sensation; but when a hard harsh surface is encountered, the foot instinctively turns to the Grass. The formation of parallel footpaths is compelled when the walk is gravelled with a hard material, or where the bottom is hard and rough, even if blended with fine material.

In making footpaths and walks, it is not necessary to take the soil out deep, as is often done, and to fill up the space again with rough materials, with the idea of making the path dry; this is just frustrating in the very worst way the first object that should be aimed at in making a comfortable footpath. A deep bottoming of stones or shingle destroys all elasticity and softness in a footpath, and does not at all add to its dryness. The line of a footpath can be made thoroughly dry, so far as draining can do it, and provision can be made for carrying off the surface water; but in order to do so, it is not necessary to dig a ditch in the middle of it, and fill in with rubble-stones but rather to drain one or both sides and leave the middle intact, with just sufficient excavation, say 4 in., on which to lay a thin coat of fine-sorted gravel, thus preserving as far as possible the elasticity of the soil underneath the gravel. A walk made on the opposite principle remains permanently comparatively harsh and uncomfortable to walk on, and becomes aggravated in very dry weather. A fact not generally recognised is, that over-dryness is exceedingly detrimental to roads and walks as well as over-wetness; we have even found it necessary to water the walks of a pleasure-ground to preserve them from breaking up from excessive treading—just as the water-cart benefits a road on which there is much driving in dry weather. Even in the making of walks, where much traffic is expected, deep excavation should be avoided. Macadam depended not on a large quantity of materials, but on a thin coating carefully laid on after the foundation of the road was built and made thoroughly dry. The most enjoyable footpaths we ever knew were made over bog-soil, well drained and levelled, with just a thin coating of fine river gravel over the surface; and there seems no reason why bog-soil, where attainable, should not be substituted for harder material for the bottoming of footpaths. On the modern iron road, the different sensation of the stone sleeper and the wooden one is at once felt. We do not, however, wish to discuss the question

in detail how walks should be made; we only want to show that something imperfect in their construction, or something very wrong with their surface, compels people to take to the Grass, and so form the offensive footpath.

The direction which walks and footpaths should take about pleasure grounds and parks is a question that should be well considered, by landscape and other gardeners, in first laying out places; for this, if not attended to, will be a source of irritation ever after. These are often, indeed generally, laid down in an arbitrary sort of way, to complete the symmetry of a plan to be afterwards blotted out or abandoned and another course substituted. The current of humanity, like water, is difficult to divert from a natural channel. Footpaths are always an eyesore, especially when they cross fences; indeed nothing seems to impede the course of a footpath; one instance of this is daily under our notice, where the offensive line of marshcrosses a Grass plot over two iron fences, two walks diagonally, a shrubbery, a plantation, a wall 8 ft. high with two wires stretched on the top, and finally a deep fosse or ditch. It is just Suez or Nicaragua on a small scale—the path must be made sooner or later. In thus recognising the footpath as a route for the made walk, we

put an end to all stiff formalities in the matter of walk-making and in laying out grounds. A walk must lead to somewhere, and be for some use, and not a mere streak of gravel on which nobody has any desire to travel. It does not necessarily require to go straight—very few bye-paths do—but should rather have a tendency to curve right and left.

If the natural blending of the useful and ornamental were more generally recognised—always giving the useful the first thought—there would be fewer troubles with bye-paths. We could mention almost off-hand a dozen places where the kitchen garden produce cannot approach the kitchen without crossing under the principal windows, and being carried through the pleasure-grounds, unless a very wide détour is made. In other places the lines of walks are made to join at long acute angles, where the temptation is irresistible to cut across. Carriage-drives which people are expected to follow are made to deviate for some view or effective bit of scenery, and so in the end a bye-path is sure to be made. We could

name places with enormous expanses of sterile gravel walks leading to nowhere and useless, and where a constant war is waged with bye-paths in the shape of notice-board's, iron hoops, and stumps. No wonder a taste is growing up for the wild garden, the wilderness, and the woods, with cool and natural footpaths made at a fraction of the expense required for acres of hard gravel, and infinitely more enjoyable.—“The Gardener.”

The Gooseberry Gourd (*Cucumis Grossularia*).

The Old Double White Rocket.—I have a good plant of this which I brought from the neighbourhood of Manchester a year ago. It is dwarfer in habit, less spreading in growth, and with smaller leaves than the French white double Rocket so commonly grown about London. The flowers, too, are pure white. I have from time to time received many enquiries about this plant, and as to where it could be obtained, but this last question is a very difficult one to answer. I have now quite an interesting collection of Rockets; there are the white I have named, and, in addition, I have the old double purple, the new dwarf purple, and the new crimson. What these will prove to be I cannot say till they come into flower, which they soon will do, as I have good plants in pots. If they prove to be distinct they will make a very interesting group indeed. The dif-

ference in the character of the foliage of the two white types is much more marked than in the case of the purple varieties; and probably the last may not prove to be so distinct as they are represented to be.—R. D.

GARDEN DESTROYERS.

THE GARDEN CARABUS.

(CARABUS NEMORALIS.)

THE various members of the family to which this beetle belongs are among the gardener's most useful friends, as with very few exceptions they are carnivorous, living on small slugs, worms, caterpillars, and other insects. The garden Carabus (this insect is named *Carabus hortensis* by some authors) is one of the largest of this family, and is a deadly foe to the cockchafers, not only destroying their grubs, but attacking and killing the perfect insects whenever one comes within its reach. The females when laying their eggs in the ground often fall a prey to them. The benefit gardeners derive from these useful insects is simply incalculable, and it is the greatest pity that so many persons look upon them as unwelcome intruders in a garden, and kill them whenever they have an opportunity, instead of encouraging them in every way. The garden Carabus belongs to the family of beetles called Carabidæ, which are nearly all carnivorous both in the beetle and grub states. This family contains a great number of members, about 307 of whom are natives of this country. They vary very much in size and form, but are all very active, and can run with

Grub of *Carabus auronitens*.

Carabus nemoralis.

great rapidity. Some have well developed wings, and fly well by night; others have none, or merely the rudiments of them, and their wing-cases are, as it were, soldered together. They are nearly all smooth and glossy, and usually black, dark brown, or bronzy in colour. They may generally be found under stones, clods of earth, planks, garden rubbish, or anything resting on the ground under which they can creep, or at the roots of herbage, near the foot of walls, palings, &c. They may often be seen running quickly across roads or garden paths. The largest British members of this family belong to the genus *Carabus*, twelve species of which are found in this country. They all very much resemble the subject of this paper in general form and appearance, though they differ in certain particulars from one another. Owing to the habits and food of these insects, the grubs are very difficult to rear in confinement, and, consequently, it is by no means easy to determine the time they occupy in undergoing their metamorphoses, and I am not aware that it has been done in the case of this insect, the transformations of which, however, are probably as follows: The eggs are laid in the spring under stones or some other shelter, the grubs from which are now hatched, and in about two months' time attain their full size; they then bury themselves in the earth, where they form a smooth chamber, in which they become pupæ (chrysalides), only remaining in this state for about a fortnight, when they emerge as perfect insects. Many of the beetles of this family pass the winter under Moss or herbage at the roots of trees, palings, &c. The grubs are just as voracious as the beetles, and are, with very few exceptions, carnivorous. They may be found much in the same situations as their parents, but nearly always under some kind of shelter. The perfect insect is about an inch long, and is of a very elegant form when carefully examined. The entire insect is very hard and beautifully adapted to withstand the attacks of its enemies, and to resist pressure in its places of concealment. Its general colour is a dark greenish-bronze, but the head, antennæ, legs, and the underside of the insect are nearly black. The head is small, armed with a pair of powerful jaws, and furnished with a pair of long antennæ, composed of eleven joints; the thorax is squarish, the sides terminating at the base in an acute angle. The legs are long and fine, which enable it to run with great rapidity; each leg

is armed with a sharp spine at the end of the joint nearest the feet. The wing-cases form an oval, and entirely cover the body; they are slightly reflexed at their outer margins, and finely striated longitudinally, with somewhat irregular fine lines; on each wing-case are three rows of deep, well-defined punctures. The grubs are about 1 in. long, and are black and shining; their heads are provided with a pair of strong jaws and a pair of antennæ. Their bodies are composed of twelve joints, which are well defined, the first three of which alone bear legs; the last joint is forked. The figure of a grub which I have given is copied from Prof. Westwood's very valuable work, "Modern Classification of insects," and is the grub of *Carabus auronitens*, which very much resembles that of the garden Carabus, but differs from it in the terminal fork of the body; that of the latter insect is somewhat longer, and, instead of being toothed, merely bears a few stiff hairs. Any grub, however, at all resembling this figure or description should be spared when met with, as they are not only beneficial themselves in gardens, but will in time turn into beetles, which are among the most useful insects. The pupa (chrysalis), as is the case with all beetles, much resembles the perfect insect, with its head and limbs closely folded to the body and covered with a thin, tightly-fitting skin. G. S. S.

ANSWERS TO CORRESPONDENTS.

Diospyros Kaki.—I have several healthy young seedlings of this Chinese and Japanese fruit tree. Will some one who has had experience in its culture kindly give me a few hints? Is it not nearly hardy? I have some remembrance of its having borne fruit in the open air in the Isle of Wight. I know that it fruited with Mr. G. F. Wilson at Heatherbank, and I should be glad to know what conditions as regards temperature, soil, watering, and exposure, he finds to suit it best.—T. B. G. [Mr. Wilson's plants are about 5 ft. high, and are now maturing several fruits which strikingly resemble Tomatoes in form, especially those of the Criterion variety. The plants are in pots somewhat small for their size; they receive copious waterings and are otherwise liberally treated. They grow in a good-sized house which is devoted to orchard-house fruit trees in pots, Vines, &c.; and during the greater part of the year it affords protection to hundreds of Lilies; therefore it is cool and airy, and not shaded except by the Vines overhead.—W. G.]

Diseased Grapes.—I send some berries of the Muscat of Alexandria for examination, and shall feel much obliged if you will give me some information as to the cause of their shrivelling. The water used is of the same temperature as the house, and the atmosphere that of the general temperature for Muscats. The disease makes its appearance when the berries begin to colour. The wood was thoroughly ripened, and a constant flow of fresh air night and day was kept up at back and front. The Vines otherwise appear to be very healthy.—G. P. [This is a case of what is called "shanking," a disease caused in a variety of ways, but in the present instance probably from the constant flow of fresh air night and day at back and front of the house. No kind of Grape, and particularly the Muscat of Alexandria, will stand such treatment in a season like the present. At all times cold currents of air should be avoided, but more especially till the Grapes have passed the "shanking" stage, which is, when the berries first begin to change from the sour to the saccharine state. Overcropping, a cold, wet border, or the opposite condition of dryness, and, indeed, a severe check of any kind, all tend to produce the disease; hence the remedy is obvious, viz., to avoid all these.—W. H.]

Spring Flowering Plants to be Sown Now.—Will you tell me the names of a few permanent plants, the seeds of which may be sown now, for spring or summer flowering? Also if there are any seeds of climbing plants suitable for walls, that would come up in spring? Would it do to sow now *Nasturtium*, *Convolvulus*, *Canary Creeper*, &c.? Also will some one give me the names of some perennial climbing plants, the seeds of which may be sown now? Is October or November a good month in which to plant Jasmine, *Honeysuckle*, *Virginian Creeper*, &c.—E. [Hardy climbers may be planted in October and November, or as soon as their leaves have fallen. It will not do to sow the seed of such tender plants as *Nasturtium*, *Canary Creepers*, &c. now, as if they started at once the winter would kill them, and if the seed laid dormant the wet might rot it. Sow these in the end of April. Few perennial climbers are raised from seed. Ivies, Clematises, *Ceanothus*, *Passifloras*, and similar plants are usually struck from cuttings or obtained by layers. Sow in spring under glass seeds of *Ecer-mocarpus* scaber, *Canary Creeper*, *Tropæolum lobbianum*, *Colea scandens*, *Sweet Peas*, &c., for climbers; and for something more enduring, plant climbing *Roses*, *Ivies*, *Cotoneasters*, *Ceanothus azureus*, &c. It is practically too late to get seeds to grow of any good permanent plants. All these should be sown early in the summer. Primroses, *Polyanthuses*, *Fansies*, *Finks*, *Carnations*, *Pentstemons*, *Anemones*, *Alyssums*, *Arabis*, *Aubrietias*, and many other good permanent border plants should be raised from seed sown in May; then they are strong enough to stand the winter and bloom freely the following year.—A. D.]

Names of Plants.—G. S. W.—The name of the fungus is *Agaricus lacrymabundus*, a species sometimes mistaken for the true Mushroom. *Enquirer.*—1, *Adiantum veouatum*; 2, *Pteris quadriaurita argyrea*; 3, *Asplenium bulbiferum*; 4, *Pellea hastata*. *J. A. E.*—1, *Tropæolum tuberosum*? 2, *Titonia aurea*; 3, *Muhlenbeckia complexa*. *A. E.* *Phytolacca serratifolia*. *G. B. C.*—*Sedum Sieboldi*. The leaf of *Fuchsia* is probably from the variety *Sundry*, but it cannot be named correctly from such scraps. *E. H.*—1, *Rudbeckia Newmanni*; 2, *Aster Amellus*; 3, *Chrysanthemum Leucanthemum* var. *maximum*. *J. C. N.*—*Helichrysum rosmarinifolium*. *C. C.*—1, *Achimenes tubiflora*; *Tydaea gigantea*. *E. M. D.* *Nephridium Serra*. *E. St. A.*—*Rudbeckia Newmanni*. *S. S.*—A species of *Passiflora*, probably *P. Pfordti*, but we cannot name correctly without leaves. *W. C.*—The two *Conifers* are *Cunninghamia sinensis* for the light green kind, and *Sequoia sempervirens* for that with dark foliage; the others are *Atriplex Halimius*, and the leaf is apparently that of *Ilex latifolia*. *A. H.*—*Francoa sonchifolia*; the Fern root is *Platyloma rotundifolia*. *G. F. W.*—1, *Comptonia asplenifolia*; 2, *Quercus Robur pectinata*; 3, *Corylus Avellana laciniata*.

Insects.—D.—The long box contains a species of sawfly in all its stages. The round brass box a species of *Julus*; the round paper box bees.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NOTES OF THE WEEK.

Planting on Benches in Hothouses.—A very pretty and simple system of arranging the interior of a glasshouse is adopted at Eaton Hall by Mr. Selwood. On the stone benches, which are in most houses generally bare, or covered with gravel, he places a good bed of free soil fringed with stones, with a little elevation here and there, and occasionally a fine piece of rock. This surface is then planted with Maiden-hair Ferns, creeping variegated Grass, or other free-growing and graceful plants; and it is so done that, with a slight difference of surface, a very beautiful effect is afforded, the edge of the bench being furnished with creeping and other plants that hide its stiffness. So far we have only a beautiful groundwork for any additional effects that it may be desired to add in the shape of other flowers or rare plants which may be brought into the house from time to time. These are placed between the tufts of Ferns and other plants on the well-furnished benches. A few Orchids or other choice plants will produce a much better effect in this way than when the house is full of flowering plants arranged in the ordinary way. And the same plan is adopted in the central pit of the house with a like result. Occasionally an elegant climber can be planted in the mass of soil and allowed to grow up the rafters. The house soon gets into a state in which it is very ornamental, if for any such reason as the family not being at home no flowers in pots are added. When, on the other hand, it is desirable to embellish the house, it may be done with comparatively few plants in a very graceful and effective manner, the pots for the most part being hidden behind the tufts of Ferns, &c. This plan quite changes the stiff shed-like aspect that the house would bear arranged in the usual way.

Vaccinium rugosum.—A remarkably handsome shrub bearing this name is now in flower in the Temperate House at Kew. In its present state it is about 2 ft. high and twiggy in growth. The stalkless leaves are lance-shaped, slightly toothed, much wrinkled on the upper surface, and have veins prominent on the under side. The flowers, which are borne from the axils of the leaves in clusters of from two to six, are about 1 in. long, and have a bell-shaped calyx of a dull red hue. The corolla is urn-shaped, of semi-transparent texture, and has five longitudinal ribs which are much raised. The colour is a pale flesh tint marked transversely by about ten wavy lines of deep red. The teeth of the corolla are small and reflexed, and of a pale yellow colour. Clusters of flowers are also produced from the naked stems, a character often noticeable in the *Thibaudias*, and, indeed, this plant may eventually prove to belong to that genus. It was presented to the Kew collection by Messrs. Veitch. Near to this plant is one of the same family and equally interesting, viz., *Epigynum leucobotrys*, bearing clusters of pure white, waxy fruits, each having a conspicuous black blotch at the tip.

Aristolochia floribunda.—This very singular species is a highly interesting ornament in the stoves at the York Nurseries. The flowers are trumpet-shaped, with the inflated tube bent upon itself, like a syphon, and terminated by a widely-dilated mouth about 4 in. in diameter. The outside is remarkable for the network of prominent veins, which are longitudinal as well as transverse. The inside of the mouth is quite smooth, and most beautifully chequered with large irregular blotches of a rich chocolate colour on a creamy-white ground. As is usual with the generality of the species, the strong carrion-like odour is very perceptible. The remarkable tendency to produce its flowers from the old wood, and in such profusion, fully justifies the applicability of its specific name. With regard to the foliage and general habit, it is much in the way of the better known Bird's-head kind (*A. ornithocephala*).

Tea Roses at Eaton Hall.—In some climates a little warmer than our own, the Tea Rose is in favourable places happy enough all the winter, and flowers freely; but in this country the best way, generally, is to do what Mr. Selwood does at Eaton Hall—plant them abundantly under glass, and thus give them the climate which they enjoy. At Eaton Hall, where they do wonderfully well planted out in various houses, as many as a thousand buds may be gathered in a single morning. In North America, where there is a great demand for these things, and where the winter is very severe, they are also planted out systematically as Vines are with us; but for a private place, the way adopted at Eaton Hall, of putting them

here and there wherever the situation will suit them, and allowing them to grow freely, is the best.

The Nepalese St. John's-wort (*Hypericum nepalense*).—This remarkably pretty shrub is now finely in flower in Messrs. Backhouse & Son's nurseries, York. In appearance it is much in the way of *H. patulum*, but differs from it in having a more elegant habit, more slender branches, narrower leaves, and rather smaller flowers, but which are of the same rich golden colour. As to its hardiness there can be no doubt, as it withstood the last trying winter in the open air. Another extremely handsome species, and one that should be grown in every garden, is the oblong-leaved kind (*H. oblongifolium*), also a Himalayan shrub, but of erect growth, attaining 3 ft. or 4 ft. high even at York, and studded completely with bright yellow flowers, which are of larger size than any other cultivated kind, omitting the Rose of Sharon (*H. calycinum*). At the York Nurseries this species is not so fine this season as it has hitherto been, which is probably owing to its not having recovered from the severe test it experienced last winter.

Cryptomeria elegans.—To the lover of trees it is a great pleasure to see the beautiful and distinct specimens which this tree is forming in our gardens. Its peculiar brownish-purple hue, which, with its form, makes it so distinct, sometimes deceives. Messrs. F. & A. Dickson tell us that a healthy batch was sent back to them from a person who supposed they were dead, judging by their colour, and we hear of visitors to good places expressing concern for trees of it which they suppose to be injured, but which were really in perfect health.

Bauera rubioides.—Amongst the greenhouse plants now in flower in Messrs. Backhouse's nursery, York, is a remarkably neat shrub bearing this name, and as it is by no means a plant often met with it is well worthy of notice. The plants were 1 ft. or more high, of twiggy growth, and the slender branches are furnished with small lance-shaped and slightly toothed leaves in whorls of about six. The flowers are borne singly from the axils of the leaves on the upper part of the branches, and are each about the size of a six-penny piece, with eight rosy-pink petals encircling a tuft of golden stamens, rendering the plants very attractive and pretty. It is a member of the *Hydrangea* family and a native of New Holland.

Agapanthus Mooreanus.—This charming bulbous plant is somewhat in the way of the well known *A. umbellatus*, but it is smaller in all its parts. It is, however, quite as hardy as the latter, and withstands our winters out of doors—at least it has done so in Mr. G. F. Wilson's garden at Heatherbank, Weybridge, where plants of it are now in flower which have withstood the past winter. As regards the hardiness of *A. umbellatus* we may state that we saw a bed of it at Mr. Ware's nursery at Tottenham, which was planted a year ago last spring, and Mr. Perry assured us that it had withstood the last winter with only the application of a little mulching. Near this bed was one that had been planted the present spring and the appearance of the plants apart from their size was much in favour of those that had remained out during the winter.

Pelargonium Endlicherianum.—The number of species of *Pelargonium* which approach to anything like perfect hardiness in our climate is very small, and of these this is probably the hardiest. On the rockery at Messrs. Backhouse & Son's nursery at York it has withstood the past few winters, and is apparently well established. A fractional of the adjoining ground is now in flower, and has a remarkably pretty effect. The leaves are somewhat of a heart-shaped form with irregular serration, and have a hoary appearance. These contrast finely with the flowers, which consist of two large upper petals of a deep rosy hue, beautifully pencilled with rich camellia. The three other petals are apparently reduced to mere scales, for in none of the flowers were they conspicuous.

Mormodes pardina armenaica.—This beautiful new variety has for some time past been a great ornament in the Orchid houses in Mr. Bull's nursery at Chelsea. It has long, somewhat erect, racemes of flowers of the singular form which is characteristic of this genus. They are of fine texture and of a bright orange colour instead of pale yellow as in the type, and emit a delightful fragrance. As in the type the pseudo-bulbs are elongate and terminated by a few broadly lance-shaped leaves of a pale green colour.

The Phylloxera.—Mr. David Thomson writes as follows in the *Times* of Tuesday last concerning this pest: "Several years since, when scientific experimenters were busy propounding remedies for this fell destroyer of Vineyards, I printed a letter and addressed it to the Minister of Agriculture of France, in which I stated my conviction—from my own experience of the Phylloxera in Scotland—that no remedy that could be applied would eradicate the insect without at the same time killing the Vines. I recommended that wherever the Vines were affected they should be destroyed and the ground cropped with cereals for two or three years, by which time the insect would have perished, as I had proved that

it could not exist apart from the genus *Vitis*. It is so far satisfactory to me that it appears from the letter of your Geneva correspondent, under date August 27, that the opinion and advice I tendered to the French Minister of Agriculture seems to be in process of being proved correct; for, as shown by your correspondent, all attempts at checking the devastating ravages of the Phylloxera on the Continent have proved futile. Your correspondent's account of the attack in the Vineyards at Chambéry, 'where they were cut down and every branch burnt on the spot, and the ground sown with quicklime,' and that from that time there has been no further appearance of Phylloxera in the canton, so far proves my own experience and the advice I gave to be correct. Again I would reiterate my conviction that no remedial measures having for their object the destruction of the insect and the saving of the Vines will ever prove successful, and that nothing short of a simultaneous stamping out of the affected Vines will save the French and other Continental Vineyards from destruction as far as any human means are concerned."

Rogiera gratissima.—This old favourite certainly now-a-days needs but little recommendation, but the gay appearance which it presents at this season in the greenhouses at the York Nurseries, suggested the present note, as in few places is it grown so successfully as it is there. The plants under notice are planted in boxes nearly 3 ft. square, liberally treated, and grown in a well ventilated greenhouse. The result is abundant and continuous flowering, and complete immunity from the insect pests which infest the plants when grown in a high temperature. For cutting purposes there are few more desirable plants at this season, for combined with the delicate blush hue of the flowers, with their deep rosy tubes, they emit a delightful perfume which fills the houses in which they grow.

Oncidium dasystyle.—This singular Orchid is one of the prettiest and also one of the most uncommon amongst the large number of Oncidiums in cultivation. Its flowers are borne in the usual racemose manner, and are about 1 in. in diameter. Their ground colour is a creamy-yellow with the sepals mottled with chocolate, and the wings of the column profusely spotted with that colour, giving the blossoms a pretty appearance; but the most remarkable point about them is the rich black crest at the base of the lip partly brightly polished and partly velvety, which, taken together with the general form of the flower has the appearance of an insect. It is a native of the Organ Mountains; hence in cultivation it requires an intermediate temperature. It is now finely in flower in the Royal Exotic Nursery, Chelsea.

Aralia spinosa.—At this season, when the number of hardy shrubs in flower is but few, this *Aralia* is especially welcome, the huge plumes of white flowers terminating the branches, which are furnished with handsome, broad, pinnate leaves, having a striking effect. Another elegant shrub, and one that so closely resembles this *Aralia* that it is often mistaken for it, is the Mandshurian *Dimorphanthus* (*D. mandshuricus*), which has the additional property of being hardier, a decided advantage in the northern counties. In the York Nurseries we noticed grand examples of both shrubs, but the *Aralia* was considerably more injured during the past winter than the other, and bears at the present time unmistakable evidence of its severity; consequently it is not such a grand object as it has been in former seasons.

Tricyrtis hirta nigra.—We saw a few days ago a variety of the well known Hairy *Tricyrtis*, bearing this name in Mr. Stevens' collection, which is well worthy of notice. As regards size, habit, &c., it is the counterpart of the type, but the flowers are very much darker in colour, being a black purple mottled here and there with specks of a lighter hue. As an autumn flower it is a valuable acquisition; it is very floriferous, and grows vigorously when planted in a partially-shaded place in a damp border of peaty soil.

Monstrous Lily.—One of the most remarkable instances of the fasciation of Lily stems came under our notice a few days ago. It was a stem of *Lilium auratum* sent to Messrs. Veitch & Sons from Dr. Harris' garden at The Grange, Lamberhurst. It bore 150 flowers of moderate size closely arranged and formed a symmetrical cone 17 in. high and 16 in. in diameter at the base. Mr. Myles, the gardener, asserts that he had two such examples amongst his Lilies this season. A similar instance of this floriferous tendency was communicated by Mr. G. F. Wilson. The plant in question bore 123 blossoms on a stem 6½ ft. high and was twice the girth of a man's thumb at the base.

A Large Century Plant.—On the lawn of Mr. John F. Phillips, residing at Brooklyn, New York, may now be seen a magnificent specimen of the Century Plant (*Agave americana*), which will be in full bloom in a few days. This is believed to be the largest plant of the species ever grown in the temperate zones. It was brought here from Cuba, in 1874, since which time its growth in size has been scarcely perceptible, with the exception of the enormous stalk or flower-spike, which first made its appearance on the 12th of

July last. This has now attained the height of 22 ft., and the circumference at the base of 5 in. When fully grown it will fall little short of 30 ft. in height in all probability. Its thick lanceolate leaves are 7 ft. long, and the diameter of the plant is thus about 15 ft. At the top of this immense flower-stalk the flower-spikelets have already grown out at irregular intervals, some of these having reached 2 ft. in length. The late cool weather here has somewhat retarded the bloom, which is now most anxiously awaited. It is estimated that it will produce 1000 separate blossoms, and it is regarded by all who have seen it as a great floral curiosity. Large crowds of people are attracted to the grounds daily. If any of our European friends have succeeded in growing still larger specimens of this curious plant, we would be glad to hear from them.—H. HENDRICKS, Kingston, N. Y., U.S.A.

Campanula pyramidalis as a Border Plant.—The long and handsome mixed borders by the walls in the College Gardens at Dublin are now adorned by very striking pyramids of this fine old plant. Some of them are well over 6 ft. high, gradually tapering from a rather wide base to a pointed top, and furnished with myriads of blossom. They are effective at a great distance off, showing well against the foliage of the well-covered wall behind the border. The white variety is, if anything, more beautiful than the blue. Considering the value of this fine old plant, both for the outdoor and indoor garden, and also for rooms, halls, or windows, it deserves more attention and better culture than it usually gets.

The Rock Daphne (*D. rupestris*).—This miniature shrub has been aptly described as a "real Alpine Gem," and certainly it is a gem that cannot be too well known, whether it be for adorning the rockeries of those who especially love Alpine flowers, or as an ornament in an ordinary greenhouse, for which it is alike admirably suited. Its usual season of flowering is in spring and early summer, but the second crop of flowers, which render the plant beautiful at the present time, is no less welcome, and is further evidence of its high merits. In the York Nurseries it is now bearing its clusters of deep rosy blossoms on plants grown in pots, and their powerful yet delicate perfume is very grateful.

Japanese Privet as a Flowering Shrub.—Among the few flowering shrubs which the severe weather has left us we noticed this, very fine, in Messrs. F. & A. Dicksons' extensive nurseries at Chester; in the form of small grafted standards, and also as very dwarf plants on their own roots it seems to flower more effectively than is the case with ordinary specimens. Some plants, not more than 1 ft. high, had a good many flowers on them, and young standards were also full of them. It is a perfectly hardy shrub, having stood during the past winter when other new Privets perished.

Grouping in Greenhouses.—We noticed in the gardens at Browne's Hill near Carlou, a way of grouping the plants of various families together in the houses, which is an improvement on the ordinary mode of arrangement, or at least a desirable change. For example, the Coleuses were together on one bench, and the same plan was carried out with groups of Ferns, Dracænas, and the like. This prevents the monotony which results from the system too often followed, and which prevents much interest being taken in the plants. There is nothing like this prim dotting system in Nature. The grouping plan does not preclude effective mixtures when desirable as they would be if for contrast only.

Tropæolum Triomphe de Gand as a Roof Plant.—This has a wonderful effect in the great corridor at Eaton Hall, where it is trained on the roof, its shoots hanging down straight as cords for many feet, dotted with brilliant flowers—that is to say, it grows up 15 ft. or more to the roof, and hangs down 6 ft. afterwards. In the same position in the corridor grows the *Abutilon vexillarium*, which seems equally free and graceful.

Testimonial to the Rev. H. H. D'Ombraïn.—It is proposed to present the Rev. H. H. D'Ombraïn with some acknowledgment of the service which he has rendered to floriculture by his writings and practical support; and more especially to the culture of the Rose by establishing a "National Rose Society." The proposal has the assent of the Rev. Canon Hole, President of the National Rose Society (to whom subscriptions not exceeding one guinea may be sent), and other eminent Rose growers.

Ipomœa bona-nox.—It is surprising how seldom this remarkable stove plant is grown. Its large white trumpets are so valuable for taking indoors in the evening, when they open and have such a delicate odour, that it is used for this purpose at Eaton Hall; there it is trained along a wire in a warm house.

Fuchsia gracilis.—We notice a stock of this elegant hardy Fuchsia in Messrs. F. & H. Dicksons' nurseries at Chester. The Fuchsia called Tom thumb, though quite distinct, is sometimes called *gracilis*, though it has no claim to the name. Can any one tell us about the origin of this?

THE FLOWER GARDEN.

APONOGETON SPATHACEUM VAR. JUNCEUM.

THIS pretty addition to out-door aquatics was sent to Kew a year or two ago from British Kaffraria. It has since then been somewhat widely distributed in English gardens, owing to the freedom with which it may be raised from seeds which are produced each season in abundance. Unlike its better known congener, *A. distachyon*, it is of erect habit, and is altogether a smaller growing plant. Its flowers, which are arranged in a fork-like manner, are tinged with rose. They are, however, quite devoid of scent, a property so much appreciated in *A. distachyon*. Its varietal name is derived from its rush-like leaves, which in the type are considerably less terete. It thrives best in a shallow running stream, submerged about 2 in. It delights in any gravelly soil, mixed with fibry loam, and a small quantity of leaf mould. As to its absolute hardiness in this country

Aponogeton spathaceum var. *junceum*.

we are unable to speak, as during the last winter it was afforded the protection of a frame, on account of its comparative rarity. Our engraving was prepared from the original plant received from South Africa, which flowered in the out-door aquatic tank at Kew during the present summer.—W. G.

DUTCH BULBS FOR SPRING DECORATION.

(THE HYACINTH.)

JUST now, when the summer's hues are deepening to autumn crimson, and the great change which leads on to the decay of winter is slowly passing over the face of Nature, attention may properly be turned to the seasonable matters of selecting and cultivating the many sorts of Dutch bulbs that have found their way into the market, and for urging the necessity for losing no time in making selections, so as to ensure the highest degree of success at the blooming season. The bulb farms of Holland have been steadily increasing their acreage for this sort of produce year by year to meet the demands made upon them by this and other countries. The trade with Great Britain is enormous, and must be set down to the growing taste of the community for much that is beautiful and charming amongst flowers.

Of the many Dutch bulbs, the Hyacinth, Tulip, and Crocus are the most important, because the most ornamental and most diversified in colours of all the productions from Holland, and therefore better worthy of general cultivation, especially when growers have limited means and restricted accommodation. Such plants as the varieties

of the *Narcissus* are beautiful enough and rich in colour, but they are by no means so showy, neither are they so well adapted for what is technically termed indoor decoration, their foliage being apt to become spindled in a confined atmosphere—much more so than that of the *Hyacinth*—and the flowers proportionately weak and wanting in colour and substance. They do very well, however, for blooming in pots in March; but, with the exception of the *Polyanthus*-flowered types and the *Jonquil*, are not good forcers. These, then, form the most important bulbs for winter and spring decoration, for small growers more particularly. Those who grow bulbs more largely have their *Ixias*, *Sparaxis*, *Babianas*, *Nerines*, *Fritillarias*, *Tritonias*, and other miscellaneous subjects, some of which are not of Dutch origin, but all blooming in winter and spring, and forming features of rare beauty when in flower. Of course, the stately *Anaryllis* forms the most aristocratic section of all the bulb community, and where there is anything like warm greenhouse accommodation no person should be without a few, for they only require to be seen to excite admiration, and half the care and attention bestowed on *Hyacinths* will be productive of satisfactory results.

Hyacinths, *Tulips*, and *Crocuses* are bulbs for the million, because it happens to suit their constitution to a nicety to be in total darkness for two or three months during the growing season, and at the same time they are very convenient for all those who have nothing but window space for their disposal. The bulb, as soon as it comes in contact with a humid atmosphere, pushes roots into the soil in one instance and into water in another, and it is a very strange fact that the roots, in the case of a *Hyacinth* in a *Hyacinth* glass, will live and luxuriate in water alone, when they would perish in earth and water if the one was not properly proportioned to the other. This in all probability accounts in many instances for the oftentimes unsatisfactory yield of bloom for first-class roots. If cultivators would only reflect one moment upon the nature of bulbs they would perceive that a vast amount of nutrition is stored up in these concentrated layers of vegetable matter to be given out during the season for the benefit of both root and stem, and the wisdom of acting with intelligent caution would be more apparent.

It used to be laid down as an axiom that the bulbs will produce the best flowers that have not a single drop of water given to them for the first two months after planting. This refers more particularly to the case of *Hyacinths* in pots. The soil intended for their growth should be rich and open, full of fibre, and sandy in its nature. All ingredients likely to incline to a soddened character should be strictly avoided. In potting leave one-third of the bulbs above the soil, and the soil should be pressed firmly about it, but not immediately below the base of the root; why? because many of the *Hyacinths* throw out strong, thick, fleshy roots that, coming downwards in a mass, do not readily penetrate the soil beneath, and in consequence the bulbs are thrust up out of it, and have to be replanted again to the danger of injuring the roots. If the mixture be as it should be, of an elastic nature the roots will soon penetrate it, and one great secret of success in cultivating *Hyacinths*, whether in pots or glasses, is to get a good and free root action as soon as possible.

The previous remark about not pressing the soil too hard just under the base of the bulb applies to those who do not put their pots out of doors under a covering of coal-ashes or some such material. When the latter course is followed—either by placing the pots in a cold frame or on an ash bottom in the open ground—the weight of material resting on the surface soil of the pots prevents the bulbs being thrust up out of the soil when a strong root action commences. Some growers invert a small pot over the crown of the bulb before covering with *Cocoa-fibre*, *cinder-ashes*, or such like, and this should be put in to the depth of 4 in. The presence of the inverted pot prevents the covering from coming into immediate contact with the growing spike, and prevents anything like rot. When not so protected, the tips of the growing spike will become disfigured, and this disfigurement shows itself at the points of the main leaves afterwards. When once covered up snugly, the pots need not be looked at for six weeks or two months.

Hyacinths that are intended for exhibition purposes, or that are required to be grown as fine as possible, should be repotted about the middle of October, and another lot early in November. We have known very fine *Hyacinths* obtained from bulbs potted as late as the second week in December, but unless the roots are carefully preserved they are apt to become dry and shrivelled. *Hyacinths* and other bulbs that are exposed to drying influences in shop windows are apt to suffer in this way.

All who cultivate *Hyacinths* know that the varieties differ greatly in the matter of constitutional vigour. Some incline to large bulbs, producing, however, flower-spikes of medium size; and as in the case of *Tempel Van Apollo*, single red, many of them. Large fleshy roots are apt to do this. Others, of which a notable example will be found in *Duke of Wellington*, double red, never produce but an ordinary sized bulb, and yet it very frequently produces an immense

spike of large fully double flowers. It is a mistaken idea altogether to suppose that the largest bulb of any given sort produces the largest spike; and although it is quite true that a very good judge of what bulbs ought to be, could make a selection of capital flowering roots, it may and does happen that he has passed over some equally good and many much better. On the proper treatment of the bulb depends mainly its success, in a flowering point of view; but it must, however, be borne in mind that skilful cultivation is a powerful auxiliary towards bringing out the true character of the spike and the substance and colour of the individual blooms.

For the benefit of those who wish to have bulbs blooming from Christmas onwards, we may state that the roots should be potted forthwith. If planted in the proper material, and treated as already indicated, the pots will be getting tolerably full of roots by the second week in November. The grower can then select as many as are required of the earlier-flowering varieties, place them in a warm greenhouse temperature, there to remain for three weeks or a month; then they can be removed to a stove house, placing them as near the glass as possible, and allowing the pots to stand in saucers, which need to be kept in water. There are not many Hyacinths well adapted for forcing, but the following are most useful for the purpose: Homerus and l'Ami du Cœur, single red; Waterloo, double red; La Tour d'Auvergne, double white; Grand Vainqueur, single white; and Orondates, single blue. The pretty double white Roman Hyacinth should not be overlooked; it is valuable for its extreme earliness and pure white single flowers, coming into flower in October and November, and, with a succession on to February. Those who make a business of forcing Hyacinths, &c. for market purposes, and require to pot them early, get their bulbs over from Holland in August; they are then potted, and placed out-of-doors in long beds, and covered to the depth of 4 in. or 5 in. with a covering of spent Hops and rich manure. Under this covering the bulbs make strong roots, and as they grow upwards, they are taken to a warm house, and pushed on into flower. The Roman Hyacinths are generally potted and placed in heat at once, where they soon become active.

Some good Hyacinths will be found amongst the following, which are all moderate in price: Double red—Lord Wellington and Noble par Mérite; double blue—Blokberg and Laurens Koster; double white—La Tour d'Auvergne and Prince of Waterloo; single red—Emeline, Fabiola, gigantea, Duchess of Richmond, Macaulay, Norma, Robert Steiger, Sultan's Favourite, and Von Schiller; single blue—Baron Van Tuyl, Bleu Mouvant, Charles Dickens, Couronne de Lille, Grand Lilas, Marie, Mimosa, Orondates, Regulus, and Vulcan; single white—alba superbissima, Cleopatra, Grand Vainqueur, Grandeur à Merveille, Madame Van der Hoop, Seraphine, and Themistocles; single yellow—Alida Jacoba, Anna Carolina, and Heroine. Those who require some extra fine varieties for exhibition purposes will find them in the following: Single red—Fabiola, Garibaldi, Koh-i-noor, Lord Macaulay, Pelissier, Solfaterre, Von Schiller, and Vurbaak; single blue—Baron Van Tuyl, Charles Dickens, Feruk Khan, General Havelock, Grand Lilas, King of the Blues, Lord Palmerston, and Marie; single mauve—Haydn and Sir Henry Havelock; single white—alba maxima, La Franchise, La Grandesse, Grandeur à Merveille, Mont Blanc, Seraphine, and Snowball; single yellow—Duke of Malakoff (sometimes classed with the single reds), Bird of Paradise, and Ida.

R. D.

ENGLISH AND FRENCH FLOWER SHOWS.

It is eminently characteristic of English people that they are incessantly running down their own country; whether it be its climate, its constitution, the manners and customs of its people, or its productions, you are always sure to find plenty of detractors, according to whom it must be the most intolerable country for any one to live in. No art, no music, no drama, in fact nothing, what wonder is it that foreigners take us at our own estimate, and conclude that a glimpse of sunshine is a rarity, and fog the normal condition of our atmosphere—that we have no taste, and that if there be anything artistically good amongst us it is of foreign origin?

Now amongst the things of which we have continually read the cuckoo cry "They manage these things better in France" is that of flower shows. An English visitor happens to drop in upon a French flower show, he sees its pretty and tasteful arrangement, he contrasts it with some formal tent which he recollects in his own neighbourhood, and he immediately exclaims "What a contrast!" Why cannot we take a leaf out of their book and aim at something better than those long straight tables, or rows of green boxes? He does not look into the matter, and hence runs away with the notion that we are lamentably behindhand. I should like, then, as one who has seen perhaps as much of flower shows in this country as any one, and who knows a little of them also in France, to record opinions

which may be somewhat opposed to these views, but which are at any rate the result of careful looking into the matter.

I am quite ready to admit that, with an exception or two, formality is the rule at our flower shows. The Royal Botanic Society has for a lengthened period held its flower shows in a tent, where the endeavours to give an artistic appearance has been successful; the undulating ground and the absence of stages (the pots being placed upon the green sward) do this; and the Royal Horticultural Society has followed it; but even in these cases it is essentially different from a French flower show. All the groups of one kind are formed together; no effort is made to conceal the pots, and, although excessively beautiful, the beauty depends more on the plants than on the arrangement. In looking at French flower shows, we are struck I think with a few things essentially different from our own. In the first place, there is the almost entire absence of the amateur stand amongst exhibitors; they are, indeed, *rara aves*. To a Frenchman, especially to a Parisien, it seems utterly incomprehensible that a young fellow with means should think of devoting his spare time to the cultivation of his garden, or should go through fatigue and hardship, for the purpose of winning a prize which does not represent one-tenth of the expense that he has gone to for the purpose of obtaining it. It is not that he does not like flowers; on the contrary, they are a real pleasure to him; but to spend money, to go through the worry and anxiety that amateurs do with us, is something he cannot understand. To go through any amount of squeezing to resort to any dodge for the purpose of getting a place at a premier representation of a new play to be made into a pancake at the reception of some grand lady, is quite a different thing, for the other he has no inclination; the exhibits are, therefore merely confined to the growers for sale. When at a recent flower show in France, I mentioned that at the National Rose Society, while there were thirty-two growers for sale who exhibited, there were eight amateurs, some considerable amount of astonishment was expressed. I hope some believed me, but there was an incredulous smile on others, which betokened that I was perhaps drawing the long bow. For somewhat of the same reason we are, I think, able to account for the comparatively small size of the plants exhibited by nurserymen. Any one who expects to find such establishments as those of Veitch, Bull, Williams, or any other of our great London nurserymen in Paris or its neighbourhood will be disappointed, for, with the exception of Thibaut & Keteleer at Sceaux, I know of none that can lay claim to anything of the kind, and in going over their houses, you see none of the grand specimens which you will find in many of our first-rate establishments. An exhibit of a French nurseryman is composed principally of what are called with us, I believe, trade plants; the enormous plants (too large perhaps) which you will find in any great London nursery, or exhibited at our great flower shows are never seen, and doubtless these smaller-sized plants are more easily grouped and can be more tastefully arranged than the larger ones, although they do not exhibit proofs of cultivation and skill as the others do. The French nurserymen have no inducement to grow these large plants. The monied classes with them do not as a rule spend their money on greenhouses, conservatories, or stoves, and hence such plants would be a drag on their hands.

The whole system of a French flower show is different from ours, and is one that we could not ensure; take for example their judging. A French flower show is never a one-day affair, it generally lasts for three or four, and the first of these, or at any rate, the afternoon, is given up to judging. A jury as it is called goes round—this consisting sometimes of twelve or fourteen persons; the plants are looked at, and much pleasant gossiping takes place. When the decision is wanted, however, Mons. A. has recognised some one at the other end of the tent, and has to be brought back; after a time a show of hands is taken and the decision is made, but as the exhibition has been arranged for effect, the exhibits in the same class are all scattered. A considerable amount of walking has to be done; thus at Brie in the class for 200 blooms of Roses, the competing exhibits were as far from one another as it was possible for them to be, and of course, if there was any difference of opinion the ground had to be travelled over several times, and imagine Mr. Baker, who so recently described his method of growing Roses in your paper a little while ago, coming up from Exeter, placing his magnificent blooms before a jury such as I have described, and then obliged to leave them for twenty-four hours before any one looked at them, when the lovely bloom and freshness would have passed away. How very different would Mr. Fish's ideas of his forty-eight have been if he had seen them there even in this cool season.

I think these few facts will account for the difference between French and English exhibitions, and will show how impossible it is for one to copy the other. Each has its points of excellence, and each must retain them. You enter an exhibition in England, and your eye is at once caught by the marvellous excellence of culture displayed before you; be it Azaleas, Pelargoniums, Orchids, Dracænas, Roses, Crotons, or Grapes, Pine-apples, or Peaches, you at

once confess that you are in the presence of plants that evidence skill, patience, and intelligence. You say, perhaps, they are somewhat stiff and formal; that it is a pity they are so orderly arranged; but you see at once how necessary it is where the competition is so keen and close, and where it is needful to be able to compare one with the other. I shall never forget the utter blank astonishment with which some of the French Rose growers regarded the marvellous pot Roses at the exhibition of 1866; nor again the surprise of the Dutch bulb growers when they came over some years ago to see the competition for the prizes they had themselves offered. In truth, nowhere in the world can we see such splendid examples of culture as with us, and it would be I think an evil day when, for the sake of getting a little more prettiness into our exhibitions, we were to discourage that close attention to growth which at present we are enabled to show.

You enter a French exhibition, and you are at once taken by the exceeding taste displayed; there is always sure to be an artistic piece of rockwork and a fountain; then from this fountain a stream runs through a good portion of the tent, and plants are amazingly well grouped round it. Probably outside the tent a garden has been extemporised; beds of flowers are arranged both outside and inside, and one's first exclamation will doubtless be, "Why cannot we introduce such a

ANEMONES IN THE SOUTH OF FRANCE.

THERE are few prettier sights in spring than a woodland carpeted with the little Wood Anemone (*A. nemorosa*), a common native plant in this country and, indeed, throughout Europe and a greater part of North America. Of similar gregarious habits are many other species of Windflower which are indigenous to the south of Europe. The annexed engraving represents a field of the old *Anemone coronaria* and its forms as it grows in the south of France, and is used in this instance to suggest that similar effects may without much difficulty be obtained in our woodlands. A sunny piece of warm, sandy ground would grow these Anemones just as well in England as in the south of France or Italy. The only difference worth noting would be the time of flowering, which would be in spring with us. To make, in fact, a turf of the Anemones of Southern Europe would be a charming idea in the wild garden. The main thing is to see that the plants are masters of the ground, and not ousted by other and coarser ones. The selection of the ground is the main thing, that is, if the colony is to be established without expense. In many large places there would be little difficulty in finding spots where they would grow. Even in heavy soils one might find dry and sunny bits of hedgebanks where the Anemones, heretofore grown in gardens, could

Field of Wild Anemones in the South of France (from a photograph).

system of exhibitions in England?" But this will I think be modified when we look beneath the surface, and see the conditions in which it is arranged.

My simple object in this short paper is to induce us to be satisfied with our own arrangements, and in no way to disparage our neighbours. I am quite sure that we could display as much taste in arrangement if we could rest satisfied with the places; and I am equally sure that they could produce as fine plants as we do, if they had the incentive to it that there is amongst us; in fact, if it would pay, we should each probably keep to our lines, and the interests of horticulture in both countries will, I conceive be best served by our so doing.

DELTA.

Colchicums and Autumn Crocuses.—These interesting autumn flowering bulbs are now coming into bloom, but being destitute of foliage they look best when the ground under them carpeted with some dwarf evergreen plant, as on bare earth their delicate blossoms get splashed by heavy rains, and flowers without foliage are never satisfactory. Where permanent Ivy edgings are used such bulbs should be planted just inside them; the blossoms then rest on the Ivy leaves, which set them off to advantage.—J. G. L.

be easily established. Our engraving only shows the older garden Anemone, but the new scarlet Anemone would prove equally hardy and free in the wild garden. V.

MIXED FLOWER-GARDENING.

FLOWER-GARDENING has been, for the season which may be said to be now gone, gardening without the flowers. The spring gardening was only a partial success, or almost a failure, from the havoc the severe winter made among plants of a herbaceous and annual character, bulbs being also late, and the whole effect patchy and unsatisfactory. The summer bedding has throughout had to struggle for existence. Tender foliaged plants, both dwarf and tall, have been starved out; exotic succulents have been rotted out; and the flowers of Pelargoniums, Calceolarias, Violets, &c., have been washed out. Such is the tale which has generally to be told, especially on retentive soils. In situations where the soil is light and porous, a fair display of flowers may be found, though of a weather beaten and imperfect aspect. Flowering plants of the bedding section, on the whole, have had but a dragged time of it.

If anything has been more satisfactory than another, it is plants of the hardy herbaceous class, whether of the low carpeting character,

as Saxifrages, Sedums, and Antennarias, or of the Funkias, Bamboos, Begonias, and such like. Even the flowering herbaceous plants have all done well, especially those of any sturdiness and substance, such as the Delphiniums, Campanulas, Alstromerias, and now even the Phloxes and Dahlias. The Spiræas, among flowering shrubs, are making at the present time a fine show, with a great variety in habit of growth and colour of flowers. These, with their herbaceous relations, are really indispensable, and destined to be much more largely planted than hitherto. It is clear therefore that our flower-gardening is entirely dependent on the state of the weather, and that since forecasts of six months cannot yet be achieved, we ought to prepare a due proportion of dull weather as well as sunshiny beds, the former perhaps predominating.

Fortunately there is a growing taste for the interesting as well as for fine gaudy flower-beds, and these may be made both showy and tasteful by a judicious mixture of herbaceous and fine foliaged plants, banding them round with edgings of the summer bedders, or embroidering them with hardy carpeting plants; or more prominence might be given to tall foliaged plants, such as Solanums, Cannas, even hardy Ferns, banded with Pelargoniums, Calceolarias, Lobelias—in short, the usual summer bedders. Many of the hardy herbaceous class of plants have been quite gay this season, and point to the fact that, by planting in rich soil, with attention, abundant watering, and thinning out the shoots as they go out of flower, the season of bloom would be much prolonged. In this way, we think, many might be found to yield throughout the summer months quite as good a show as Pelargoniums, and Lobelias, and, as far as flowers are concerned, superior to the fine foliaged plants which we have just been noting. *Geranium sanguineum* is a plant which has been equal to most bedding plants this season, and might be used with advantage to fill the centres of large beds; it is all the better too, not to have too rich a soil to grow in. Its foliage is of a bright showy green, and the flowers of a brilliant purple red.

For a yellow flowering plant, *Corydalis lutea* has been and is fine. Its foliage alone recommends it, even if it were not so profuse and continuous in flowering. For a blue edging-plant, nothing can approach *Myosotis palustris*. This past season it has been a continuous sheet of the clearest blue since March. Another little plant which is suitable for edgings has been in bloom all the summer viz., *Erodium Reichardi*, quite a carpet-plant, and it is a wonder it has not been used for that purpose before now. These four common herbaceous plants—three of them British—we feel sure would have made this summer quite a showy and lasting bed, planted as noted: the *Geranium* for a centre mass, with the *Corydalis* to follow in a band around it, then the *Myosotis*, and last the white-flowering *Erodium*. These have been under our eye all the summer, flowering in patches, and we feel confident they will not disappoint any one trying them in a bed as indicated. We have no doubt other arrangements would occur to others better acquainted with herbaceous plants. The *Veronica*s contain a large number of tall as well as dwarf-creeping species of fine habit, and showy. Some of the Everlasting Peas are quite gorgeous on heavy rich soil, such as *Lathyrus grandiflorus* and *latifolius*, but especially the last. For large beds they should be allowed to creep over some Spruce or other branches laid over the surface of the bed in the same way as is sometimes done for *Tropæolum* and *Clematis*: they then make a close compact mass, with their flowers elevated above the foliage. We can vouch for their grand effect in the shape of well-established plants, and if growing in deep soil well watered or naturally moist, they last three months in bloom. Pity they are scentless!

Annuals of the hardier sorts have had grand opportunities this year of showing off their colours and characters to advantage. Tender annuals, such as Asters, Zinnias, and Everlastings, have shared the fate of the sub-tropical bedding plants, and have consequently pushed the hardier annuals into prominence showing what is really best and worth growing. There is a richness and variety of colour among annuals which is not approached among any other class of hardy plants, and such a season as the last should arouse cultivators to the claims of the much too neglected annuals of the hardy kinds.—“The Gardener.”

—The bedding system has been discredited by an unfavourable season, and the question will occur to many observers, What will become of it? During the past half-dozen years it has been declining in popular favour, and the introduction of leaf or “carpet” colouring has not tended in any great degree to either its revival or its permanency. In many great places where costly displays have been customary the geometric schemes have been reduced in magnitude by the excision of wings and the conversion of boundary belts into shrubberies, and other contrivances that are easily improvised where needful, but do not always result in the improvement intended. In many instances complete abolition of the parterre would have been in better taste than its restriction, but individual instances are of small consequence in the consideration of the general case and the

future of parterre colouring, which is certainly in a state of transition, and must be considerably influenced by the misfortunes that have made themselves so painfully manifest.

In many instances the bedding display will be displaced by something different, whether better or worse remains to be seen. One thing at least is certain, that for the gratification of the crowd, no less than for the finishing of a picture that is framed by the daily life of its possessor, we have at command an abundance of material. Not only so, but we have material that has never been employed as it might be employed, and, therefore, in addition to material, there is plenty of room for the exercise of invention. We have not seen Phloxes, and Carnations, and Gladioli, and Roses arranged in masses according to the laws of chromatic harmony. In the disposal of rockery and border plants we have not got beyond lines, and lumps, and dots. There has been but little done as yet to combine the stately with the gay in the display of vegetable beauty, but the “sub-tropical” notion went a long way towards the indication of what might be done when the masters, able to do it, should appear, and demonstrate the capabilities of common-place material. The style of decorating we have described as “arborescent” has met with but limited recognition as yet, and often the severe flatness brought about by the use of the shears has made it only a poor kind of carpet bedding when it might have been something better. There is no such great need for flat colouring as the artists appear to think; at all events there is no great gain in manipulating evergreen shrubs so that they look like drawings in coloured chalk that one sees on the London footways. A rich foreground is wanted everywhere, more or less, in every garden; and for the most part flowers are acceptable in almost any form, but a graceful variety is to be much more desired than flatness, repetition, and monotony.—*Gardener's Magazine*.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

The Ceterach as an Edging Plant.—There is a line of this native Fern fringing a rocky border in Mr. Wilson's garden at Llandegai nearly 6 in. high and forming a beautiful and distinct kind of edging. I have never seen it better grown, but what I write to point out is how effective groups of this Fern would be in the rock garden or on a slightly raised rocky border. In Mr. Wilson's garden it is fully exposed to the sun.—V.

Gold-laced Polyanthuses.—I do not consider “A. D.'s” remarks in reference to this matter (p. 285) an answer to what stated (p. 255), although it seems to be intended as one. Judging from what he has asserted, one would think that some of the northern growers had the best Polyanthuses in 1878, whereas it was Mr. Richard Dean, of Ealing, who gained the highest prize; and it was Mr. Dean who was second to me in 1879. I do not use a richer compost for my Polyanthuses than that employed by the northern growers, and they require a 7-in. pot to do what I maintain can be better done in a 5-in. one. Is “A. D.” prepared to say that if I had cut off all the trusses but one from my plants, that the truss remaining would have had more refinement than it had? I quite agree with “Brockhurst” (p. 286) that a mass of *Cheshire Favourite* is exquisitely beautiful; it is barbarous treatment to cut away masses of beautiful pips and leave only seven. I did not know why they were removed, but must now thank “Brockhurst” for his information on this point. If the schedule of the society says that the number of trusses must be one and the number of pips seven, an exhibitor will be at no loss as to how he should act.—J. DOUGLAS.

Tropæolum speciosum.—This seems to have been a particularly favourable season in this part of the Midlands (Buckinghamshire) for the growth and free flowering of this beautiful *Tropæolum*. Roots obtained late last autumn, planted in 6-in. pots plunged in a cold frame, and planted out this spring after having made a growth of about 6 in., have been a mass of flower and fine healthy foliage for the last two months, covering a wall to the height of 10 ft. Some roots planted in the ground at the time the others were potted have not done nearly so well; so the small amount of care and protection afforded the potted plants have been well rewarded. We had the roots from the north of Scotland.—J. M., *Winstow*.

Pink and Crimson China Roses.—These comparatively neglected Roses planted in beds have bloomed continuously throughout the season let the weather be what it might. They are too often allowed to become full of weak wood, whereas they ought to be well thinned out at the winter pruning and some good rotten manure should be forked in about their roots. Thus treated the blooms will be finer and of richer colour than those produced by starved plants. Where Roses are used in large quantities for table decoration these

free flowering varieties are most useful, as the colours of both kinds are bright and pleasing, and the blooms being of medium size are more useful than those that are larger. We find them excellent for forming miniature arches, or for filling baskets formed of green Moss the edging and handle being draped with the foliage and flowers of one kind, and the centre filled up with the blooms of the other. No flower used for table decoration looks better than Roses, and specially the small-flowered common kinds with buds and foliage attached to them. To any one seeking a good continuous flowering subject to fill up beds that too often but poorly repay the trouble and labour bestowed on them, when planted with ordinary bedding plants, I would strongly recommend the old Pink and crimson China Roses, they will be in full bloom both earlier and later in the year than most plants.—J. GROOM, *Linton*.

Aira caryophyllæa.—I have often wondered why this very pretty dwarf glaucous-silvery Grass is not more employed than it is in the various styles of flower gardening at present prevalent. For divisional lines, particularly among dark foliage, it is charming, and it even makes a neat edging for walks. In parks and such places, where belts and masses of shrubs are often spoiled in effect by having an edging of some particular plant; this is a capital plant for the purpose, as it will live anywhere, and is strikingly effective. It is perfectly hardy, and the poorer the soil the more dwarf and silvery the plant becomes. I feel certain that if used along with such plants as the Crimson Beet or the Purple Ajuga, very pretty effects may be produced. No weather seems to affect it, and a few plants may soon be worked up into a thousand.—THOS. WILLIAMS, *Ormskirk*.

THE INDOOR GARDEN.

JAPAN AND OTHER CHRYSANTHEMUMS.

Who that remembers what the flowers of these were some twenty or thirty years ago would have imagined that they could have been so greatly improved, and become such objects of beauty as the best among them now are, especially when we consider how shy-seeding they are, and the difficulty there is in raising them in that way? At the time alluded to, they were little thought of; but now almost every city and town has its Chrysanthemum show, and scarcely a garden can be found without Chrysanthemums. Indeed, what we would do without them for the embellishing of greenhouses and conservatories at this season I know not, as they are the veritable "friends in need," coming in at a time when there is little else to cheer and make gay, and lasting till nearly the turn of the year, when forced plants can be had to occupy their places. Not only have our hybridists been busy in improving these now popular flowers, but foreign parts have been ransacked likewise, those introduced from Japan being most noteworthy, and exceedingly showy. Although they are not exactly all that florists can desire, they make a fine display grown as pot plants, and being somewhat loose and irregular in their petals, they are in greater favour with some than those of more symmetrical form and shape. The best and most striking of these are Red Dragon, rich flame colour; Elaine, very fine white; Fair Maid of Guernsey, ditto; Abd-el-Kader, blood-red; James Salter, pink; Cry-Kang, pink and white; Erectum superbum, bright rose; La Negresse, velvety-crimson.

Although Chrysanthemums do not seed freely in our moist climate, so as to admit of raising fresh sorts in that way, they are fortunately somewhat sportive in character, and occasionally send forth blooms of distinct colour; and the branches or shoots that bear these if propagated from, soon afford a stock of the same kind. It was in this way that the varieties named Mrs. Rundle, George Glenn, Bronze Jardin des Plantes, Golden Beverley, and many others originated, which in form and other good qualities are almost the exact counterpart of those from which they sprang. These sports among plants are not only interesting in themselves, but are often of great value, and should in all cases be watched closely and taken care of, that they may, if possible, be perpetuated and increased if found deserving. Except in a few places, cultivation has in no way kept pace with the vast improvement that has been made in the flowers, and yet Chrysanthemums will stand as many hardships as most plants, and are even more easy to grow, and are certainly more difficult to kill; in towns they seem to lead a charmed life, as they may frequently be seen covered with soot and dust, and dried up from want of water, and yet somehow or other they struggle through it all, and make attempts to put forth at least a few stray blossoms. That Chrysanthemums may be grown successfully in an impure atmosphere, has been proved again and again by the fine examples to be seen annually in the Temple Gardens, where they are cared for and tended in a way their merits deserve. If they will do so well there, it is proof conclusive that they may be had at least in as good

condition in towns and about the suburbs of other large cities besides London; indeed, they seem specially adapted for such places, and, if only kept clean by good washings overhead, and a liberal supply of water at the roots, they are sure to make ample returns in the fine heads of flower they carry. Bundled up together, and tied something in the way birch brooms are made, they stand very little chance, as all the lower leaves are stifled through want of air and light, and the stems, instead of being strong and short-jointed, are weak and drawn to at least double the length they should be.

Plants of a year old do well for the foreground of shrubbery borders, and when done with for greenhouse decoration they may be used in that way. To start them fairly, dig large holes, so as to cut any stray roots that may have got possession of the ground, and in returning the soil, work in some rotten manure for the Chrysanthemums to feed on. Thus treated, they make a fine display; but, as they bloom late, sunny, sheltered positions should be chosen, or the autumnal winds and rains soon spoil the beauty of the flowers. Where blooms of large size are required for show or other special purposes, the best way is to plant at the foot of a south wall or building, where, when they are showing bloom, they can be protected by placing lights over them, and some canvas or other shelter in front. During their growth each individual branch should be made secure, and, in order to force plenty of strength into them, the plants must be well fed with liberal supplies of sewage or liquid manure, and have the buds thinned out, so as to leave only the central or main ones.

In regard to growing Chrysanthemums for greenhouse or conservatory decoration, it is surprising how much time and labour may be saved by planting them out, and lifting them again in the autumn—a plan that not only succeeds well with Chrysanthemums, but with many other soft-wooded plants. Any piece of open ground, if not near trees, will answer the purpose; but in order to get them of large size, the best way is to prepare shallow trenches for them about a yard apart, and 1 ft. or so wide, and in digging these, to work in a little rotten manure, so that, when finished, they are about 2 in. below the general level—which will afford increased facilities for watering during dry weather, as then it is easy to give them thorough soakings without any loss by the water draining away. Into trenches so formed the plants may, if properly hardened, be turned out by the middle of May, and, if duly attended to afterwards, they will grow at a rapid rate, and form fine bushy specimens by the autumn, when they will be ready for lifting. The proper time to do this is as soon as they have formed buds about the size of small Peas; but it is highly important for the welfare of the plants that a showery time should be chosen for the operation, as then they are less likely to flag or suffer a check by the removal. The best course to pursue to get them up with plenty of roots and a good ball is to give a heavy watering a few days before the work is taken in hand, which will help the soil to keep together; and the portion of this that is not required, or that will not go readily into the size 1 pots in which it is desired to have the plants, can be worked away by the use of a small fork or sharp pointed stick—in doing which, care should be taken to preserve as many fibres as possible.

In potting, the chief thing is to use a soil that contains plenty of thoroughly decomposed manure of a mild character, such as that from an old hotbed; and in potting, this mixture should be pressed or rammed in quite firmly, immediately watered, and afterwards kept in a thoroughly moist state till the plants go out of bloom. With Chrysanthemums that have proper drainage there is no fear of injury by keeping them too wet, and especially when they have a large head of flowers to carry. The potting complete, the best situation is under the shade of a north wall, where, to keep the leaves fresh, it is necessary that they be syringed two or three times a day till they will stand the dry air without flagging, when, just before the buds expand or frost is expected, they can be moved to the shelter of a cool house. Plants so managed are far preferable to any that can be grown in pots, and they may be had of all sizes by simply propagating at different times, and planting them out up to the middle of July.

S. D.

Climbing Plants in Hothouses.—We have often protested in THE GARDEN against the very common fashion of mutilating the few climbing plants growing in the open air by tacking them against walls, and continually cutting them, the result being that it is only by accident one sees a hardy climbing plant showing anything like its natural beauty. The same miserable system obtains indoors—everything must be tied to a beam or a pillar and trimmed with regularity. The opposite system is the best one; to let the plants "abandon" themselves to the most graceful and irregular trailings that they are capable of, preventing them, of course, from unduly encroaching on other things. Attached they must, of necessity, frequently be to a slender arch or beam, but that effected, the rest is quite easy. The Allamandas, now in flower in many houses, are frequently tied trimly; but at Eaton Hall their great flower-laden

shoots are allowed to hang as freely from the arches as in their native woods, and the effect is beautiful.

TRAINING AND TYING PLANTS.

As the time of the year is now at hand when the greater portion of pot-grown plants are tied and put into the shape they are intended to have when in flower, a few words on the matter may not be out of place. It is a subject that from time to time comes in for discussion, particularly as relates to the way some plants that make their appearance at horticultural exhibitions are trained. It may with truth be said that tying at all is a necessary evil, admissible for the simple reason that with the majority of plants grown in pots, and which are likewise by necessity cultivated under glass, the effect is to induce a weaker condition of the shoots and branches to an extent that necessitates support in some way; and it will not need much reflection, even on the part of those who are not conversant with horticultural matters, to perceive that the amount of support they thus require will be proportionate to the purpose they are wanted for. Little fault, I presume, can be found with such training and tying being carried out with any plant grown under the conditions above considered, as is found requisite to keep it in the shape or form it assumes when in a state of Nature. This, of course, refers to those subjects that are more or less of a bushy habit. In the case of climbing or twining plants, the necessity for training them in a form very different from that which they take when growing in their native habitats is obvious, if they are grown at all, except as roof climbers, or in some way akin that admits of their being supported in a manner to a certain extent in accordance with their natural habit. When plants are only wanted for home decoration, all the training they require or should have is enough to keep them in shape, and to support their branches so far as need be in whatever situations they may be destined to do duty, such as when removed from the houses or pits in which they are grown to conservatories, halls, corridors, rooms, &c. But with plants that are grown with the intention of being exhibited, which necessitates their being conveyed a greater or less distance, and subjected to the shaking unavoidable in a wheeled vehicle, even when only to be moved a short distance, it becomes requisite to secure all their branches sufficiently to keep them in their proper places, and to prevent the flowers, and with some subjects the leaves as well, chafing. The extent to which this is necessary is seldom apparent to those who have not been absolutely engaged in the work. I have often seen plants that had not to be conveyed more than a portion of a mile to the place of exhibition, in such a state when they reached that no one would have cared to own them or to have used them for any decorative purpose: and yet before they were moved they did not seem to need more tying than they had received. So far as flowering plants are concerned, it should not be forgotten that comparatively few admit of being used for exhibition, or would produce the effect required, that are not naturally of a bushy compact shape, the reverse of what is usually accepted as elegant in their collective outline. This I mention by reason of the objection we frequently hear raised to what is termed the dumpy appearance of many blooming subjects shown, but which in reality are very little different in general outline from what they would be found out-of-doors in their native country. In defending the practice of training and tying, so far as it thus becomes an absolute necessity, I have done and still cannot speak too strongly against the unnecessary and equally unnatural distortion of the shoots often inflicted, where the point of every branch that holds its head a little higher than the rest is bent and tied down, so as to present an even surface, as much as if they had been clipped over with a pair of shears. This is frequently done with Heaths, and is not at all needed, as most of them naturally grow as regular in their outline as a Rhododendron bush. The same holds good with almost the whole of the hard-wooded greenhouse plants that are generally cultivated in pots.

In the case of twining or climbing plants, that must, when to be used in this way, be trained on trellises of some kind, instead of the flowers being as often tied down close in with the leaves, the points of the shoots from which they proceed, or the foot-stalks which bear them, should be allowed to stand out or hang away loosely from the leaf-covered trellis, in which way the undue formality will be avoided, instead of being, as they are now frequently seen, the whole plant as stiff and uninteresting as a Cabbage devoid of its outer leaves. But the worst examples of training are to be met with amongst Chrysanthemums and zonal Pelargoniums, as these have for some years been managed for exhibition tied down on almost flat circular wire trellises only a few inches above the pots—whereon every shoot, and often the flower-stalks as well, are twisted and distorted so as to present an even surface of bloom, giving to each

specimen much the appearance of a gigantic overgrown Mushroom. Whatever can be said in favour of this system of tying as a means by which to bring the whole of the flowers most prominently before the eye, it nevertheless makes the tortured plants look so objectionably unnatural as to be intolerable to every one not oblivious of the fact that every plant, even under the altered conditions consequent upon artificial cultivation, should be allowed to exhibit as much of its natural habit as is consistent with the general effect which it is intended to produce.

Pyramidal-shaped trellises are frequently used for training Azaleas on, and, although less objectionable than the flat monstrosities employed for the Pelargoniums and Chrysanthemums, still, the plants so managed have such a formal, rigid appearance that, however profusely flowered they may be, they are painful to look upon. In fact, the use of trellises at all should never be tolerated unless in the case of such plants as already alluded to that do not well admit of being supported by other means. There can be no question that the stiff, unnatural contour exhibited in these overtrained plants has done much to lower horticultural exhibitions in the eyes of the many who are fond of gardening and willing to countenance as much of the artificial in the cultivation of the different subjects taken in hand as cannot for the purpose required be done without, but nothing more. There are those, I am aware; who eschew the idea of all training and tying completely, beyond perhaps the support afforded by a single stake or two even in the case of pot-grown plants; but this is the opposite extreme, and is simply impracticable, unless we are to return to the cultivation in practice a generation ago, when the wretched etiolated examples of by far the greater number of subjects grown under glass merely existed in name, and were more calculated to exemplify the tenacity of vegetable life under conditions of starvation than to illustrate what can be done by a close study of their requirements and equal attention to their wants.

In regard to growing plants especially intended for exhibition, the primary object should be to produce them in a condition that will bear evidence of the highest standard attainable of healthy vigour, which, with those cultivated for their bloom, will be evidenced by the greatest profusion of fully-developed, highly-coloured flowers. There will, I think, be no question that in the description of plants mentioned this should take precedence of the graceful elegance required, and also desirable, but usually present to a greater extent in plants of a different character, and which, in the case of these latter, the cultivator should make it his chief aim to display. Assuming that this is a common-sense view of the subject, it becomes evident that, in cultivating plants for exhibition, the training and tying requisite are such as best calculated to show the properties the different subjects are grown for. This will be found to lie in a medium position between the handiwork of those who over-tie and those who deprecate any tying at all. It may be well to remind those who entertain this latter view that horticultural exhibitions, to effect the object they are professedly organised to serve, must continue to shape their course so as to illustrate and encourage individual excellence in the cultivation of the different subjects invited to compete, rather than bring together an assemblage of indifferently grown plants that, however well adapted to form a pleasing and artistic combination collectively, have an adverse effect to the promoting of that high standard which has made the cultivation of plants in this country justly famous. I have thus attempted to draw the line in this often-discussed question of plant-tying in a way that avoids the intolerable formality so often met with and yet leaves the cultivator the requisite scope for showing to the best advantage the healthy development that it is possible to impart to plants grown under conditions by necessity artificial in the highest degree. T. BAINES.

New Fire-place Jardinière.—This, the invention of Messrs. Barnard, Bishop, & Barnards' of Norwich, consists of an ornamental cast-iron box provided with hooks suitable for attaching it to the bars of the Slow Combustion Stoves made by that firm. It is light and portable, and when arranged with flowers forms, as will be seen by the annexed illustration, a striking contrast to the hitherto unartistic arrangements resorted to for decorating stoves when not in use. Being made with that neatness and taste which characterises all Messrs. Barnard & Bishop's manufactures, it cannot fail to answer the purpose for which it is intended.

Rough Plate Glass.—I find that there is a general opinion among gardeners that this is a mistake. It does not quite do for shading in the summer-time, and it prevents the free admission of all the light wanted in winter.—B.

Sweet Peas in Window Boxes.—We have noticed a pretty use of these in which the plants are allowed to hang downwards from the box in windows. Would it not be a good plan to sometimes change the occupants of window boxes?

ORCHIDS UNDER COOL TREATMENT.

As the result of a little practical experience may be useful I send a few observations respecting the behaviour of cool Orchids here last winter both in a cool house and in a house altogether unheated by artificial means. I am the more anxious to furnish my testimony in favour of cool treatment when I consider that although almost all of the Orchids to which I shall allude were known to botanists for many years, and had been frequently imported in quantity, it was not until cool treatment was practised that they were seen in anything like good condition. So bad were they indeed under the old system that when they were imported in later years and grown to perfection in cool houses many of them were regarded as new plants, not being even recognised by those who had had examples of them in their care for years. I, myself, who was among the first to note the improvement which took place in such plants as *Odontoglossum* when placed in a cool airy house often think of the poor shrivelled specimens which I had 20 years ago in the so-called Mexican house, and wonder that tradition should have so long blinded me to their wants. I think, therefore, it is of the highest importance that it should be distinctly understood that notwithstanding their ability to withstand a high temperature for a time, owing to the ease with which they almost immediately start afresh after having completed one growth (a peculiarity which alone saves them), a high temperature is neither necessary nor beneficial. Excessive heat is not an assistance to plants to which it is not natural, neither in hastening nor improving the growth; as the result of careful observation I am prepared to say that the pseudo-bulbs of *Odontoglossum* are formed as quickly in a temperature of 55° as they are in one of 75°, while in the cooler temperature the leaves are shorter. All of us who have had the handling of Orchids for a number of years are aware that almost any Orchid if taken at the right time, *i. e.*, just as it starts into growth, will stand great heat; but in giving it the greatest watchfulness is necessary in order to keep the plants well supplied water, and in moving them to a cooler place as soon as they have finished their growth—attentions altogether beyond the reach of what have now become a large class of Orchid lovers; *i. e.*, those who cultivate a few Orchids themselves with the best means which they have at command. For a long time this class of cultivators were debarred from the pleasure of growing Orchids, thinking that they all require great heat; but now that we have found a section that will stand cold, and which are to my knowledge embellishing many a cool greenhouse, let us not replace them in the old, and to many objectionable, stovehouse.

I am aware that many good cultivators of *Odontoglossum* and *Masdevallias* give their plants much more heat than others, and to those who give heat and yet grow their plants well, I say continue to do so; but to publicly advocate the maintenance of a high temperature to plants which will thrive well in a cool house is a dangerous thing to do. I have known houses in the same establishment in one of which Orchids would thrive in a high temperature, and in another, into

which the same plants had been put and subjected to the same temperature, they would not, but when subjected to cool treatment they succeeded in each house equally well. Cool treatment, therefore, in this case is the proper treatment to advocate, and it suits small growers, who derive as much pleasure from their collections when in thriving condition as the possessors of large collections do from theirs.

Let those who have appliances and experience (particularly experience in their own houses) grow their plants as they find them do best. For my part I practise what I preach, and, while I can show one of the healthiest and most vigorous houses of cool Orchids one would wish to see, on which insect of any kind has never been (except an occasional and inevitable green fly), I can point to more than one collection grown on the other system which are in anything but a happy condition. It is pretty well known that I place the minimum night or day temperature at 45° Fahr., and I am happy to

be able to say, from my experience of last winter, that no harm will take place if the house gets as low as 40° (provided the plants have been previously kept cool); indeed, my cool house last winter, when I went in at night, was frequently down to 37°, and it would have rather startled some growers to see fine *Pleiones* on a shelf with their naturally withering leaves frozen against the glass in ice about $\frac{1}{4}$ in. thick; those plants are now in very fine condition, showing well for flower. From this fact, and from experimenting in the house without a heating apparatus, in which *P. maculata* and *P. humilis* wintered fairly well after being subjected to from 5° to 14° of frost for weeks, I am sure that we cannot put the loss of the many cartloads of these plants imported down to cool treatment; I feel certain that they would pass the winter far better in a cold frame on a raised stage and covered lightly with about 3 in. of very dry Moss than they would in the heat to which they are generally subjected. In the cool house which ranged from 5° is the proper 37° (4 number) to 55° were over 500 plants of *Odontoglossum crispum* (*Alexandra*) and *Pescatorei*, 300 *Halli* and others of the *O. luteo-purpureum* section

Fire-place Jardinière.

500 *O. cirrhosum*, *O. naevium*, *O. gloriosum*, *O. odoratum*, and others of that section; some hundreds of *Masdevallias*, and more or less in quantity *O. pardinum*, *O. nehnosum*, *O. maculatum*, *O. madrense*, and indeed some of almost all of the *Odontoglossum* and *Oncidium* species said to like cool treatment, notably *Oncidium macranthum*, *O. Phalaenopsis*, *O. cucullatum*, and *O. tigrinum*, which did remarkably well; *Celoglyne ocellata*, *C. harbata*, *Cymbidium eburneum*, *C. Mastersi* (these are now showing flower), *Epidendrum syringæthyrsum*, *E. erubescens*, *E. vitellium majus*, *Lælia majalis*, *L. autumnalis*, *L. anceps*, *L. furfuracea*, *Mesospinidium vulcanicum*, *M. sanguineum*, *Dendrobium Falconeri*, *Maxillaria grandiflora*, *M. venusta*, &c. Far from being injured all these and many others continued in the most robust health, their pseudo-bulbs swelling and shining and the *Sphagnum* growing until it was beautiful in itself, the only precaution taken to ensure such a happy state of things being to take care and not have much water about, particularly in the afternoon. These plants have now a mass of roots; so well rooted are they that

one may lift them up by the leaves without disturbing them, and many of them are now in flower. I shall be glad to show them to anyone interested in cool treatment, and who can spare an hour to inspect them. I may add that I never allow our cool Orchids to be syringed or watered over the foliage at any time.

In the first week in May, or as soon afterwards as the season will permit, it is my rule to have the coolest Orchids placed in a north house in which there is no heating appliance of any kind, and there they remain until the first week in September, when they are moved to a heated cool house for the winter. On removing the bulk of them last September it occurred to me to leave one of each kind in their cold quarters throughout the winter, in order to test their powers of endurance. All went well up to the time when the thermometers inside registered 2° of frost, and I verily believe that the whole of the plants experimented on would have passed a short period at that temperature in fair condition. At from 2° to 5° of frost first went *Mesospidium sanguineum*, then *Odontoglossum Lindleyanum*, followed by *O. cirrhosum*. At from 5° to 7° of frost *O. Hallii*, *O. roseum*, *O. gloriosum*, *Masdevallia Harryana*, passed away in the order in which they are named, soon followed by *Odontoglossum Pescatorei*, and *O. Alexandræ*; and I was pleased to note that these two last, which were the most beautiful, were the hardiest of the New Granada *Odontoglossums*, and really seemed at one time likely to pass the winter in a living state. What surprised me most was the extraordinary hardness of the Mexican Orchids, *Lælias*, *Odontoglossums*, &c., which, notwithstanding that the thermometers inside the house on one occasion (on Christmas eve I think) registered 14° of frost, all passed the winter alive, but most of them dropped off one at a time during the summer. Singularly enough, two of the most frail looking are the only *Odontoglossums* left alive, viz., *O. Rossi* and *O. Cervantesi*, and these are in a healthy condition and growing well; they were small plants when the winter commenced and they have only lost two or three old pseudobulbs each. *Dendrobium moniliforme* (*japonicum*) is in as good condition as those in the cool house, and *Calanthe Sieboldi* and that bought as *C. japonica* is in a much more vigorous state than those left in the cool house and evidently consider they have been properly treated. *Pleione humilis* and *P. maculata* are living and sufficiently well to prove that they can never be stove plants. Knowing that they did not require heat, two-thirds of the bulk of *Disa grandiflora* were left in the unheated house, and the result was that they passed the winter in from 5° to 14° degrees of frost, frozen for weeks as hard as frost could make them, in better condition than those in a cool-heated house, and flowered beautifully; so satisfactory indeed was the experiment that I shall never again feel justified in placing these plants in heat while I have a quiet sheltered unheated house in which to put them. These results will, I think, warrant my saying that Orchids of the classes just named do not require much heat, they cannot be grown in heat, in fact, unless in houses exceptionally well adapted to their wants, and by experienced growers, these I leave to themselves, I write only to those who love Orchids and have but little or no experience in their culture. *Odontoglossum vexillarium*, *O. Roezli*, *O. Phalenopsis* I always keep in the intermediate house.

Pine-apple Nursery, Mañila Vale.

JAMES O'BRIEN.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

The Fuchsia-like Begonia Round an Arch.—This well known *Begonia* is planted on each side of a large arch in the great glass covered corridor in the gardens at Eaton Hall. The two plants meet above the span of the arch, which is 10 ft. high, covering the whole beautifully and producing a remarkably pretty effect.

Jasminum Sambac.—It is so seldom that one sees a stove Jasmine well-grown that we had the greater pleasure in noting a vigorous specimen of this in the warm house at Eaton Hall planted out in a bed of earth on the raised pit of a lean-to house. Mr. Selwood tells us that it bears racemes of flowers nearly 18 in. long, and it is as free in growth as a Privet.

Carnation La Belle.—I was pleased to see in THE GARDEN a short time ago a note on this the most useful of all white Carnations. When at Croome Court the other day I saw some plants of it trained on an iron rod, over the pathway of a light span-roofed greenhouse, doing well. They had been in the same pots two years, and blooms could be cut from them every day in the year. They are useful for making button-hole bouquets, and I would recommend everyone to grow this Carnation wherever white flowers are in demand.—J. C. F.

Salvia splendens.—This useful autumn-flowering plant will now be coming into bloom, and, being rather tender, should be at once moved under glass. The brilliant colour of its blossoms makes it an

excellent plant in conservatories and other plant houses during the duldest months of the year. If kept in an intermediate temperature and well supplied with weak liquid manure, it will continue to produce a succession of flower for a long period. Mixed with *Chrysanthemums* it produces a striking effect, and, being very easily grown, it should be included in even the most limited collections.—J. GROOM.

Todea superba.—Many cultivators of Ferns are deterred from growing the beautiful Filmy Ferns under the impression that they require to be grown in air-tight compartments. I have some healthy specimens intermixed with ordinary Ferns in a house with a north aspect that has had both doors and windows open whole weeks together, and yet they are as healthy and vigorous as need be.—J. GROOM, *Linton.*

TREES, SHRUBS, AND WOODLANDS.

WOODLAND WORK FOR OCTOBER.

FINISH pitting and other preparations of the land for late planting, and clear up arrears of ditching, hedge-brushing, and the erections, repairs, and painting of wood and wire fencing; also cart all road and fencing materials and remove timber from the rides wherever such is left. While dry-weather continues tree-washing may proceed; fences intended to be game-proof around nurseries and young plantations may also be examined and repaired. Stake and tie trees and tread or well ram up the soil around large and early transplants. But the principal work of the month should be planting; and to prevent a recurrence of the casualties of last winter this should be got in hand early. Where the trees are obtained direct from the home nursery they may be raised and replanted the same day, and if the work is carefully done and the soil dry and warm, they will feel the change very little. In order to preserve the roots uninjured the first row to be raised should have a good deep trench thrown out alongside it, sufficiently deep to undermine the roots, and this operation should be continued for every succeeding row. There should be no violent pulling at the stem and no chopping of roots with the spade; but every part of the work should be conducted with care and deliberation.

The tools required for raising and planting are simple, but they should be handy in size and of the best materials. The following will be found useful: A small three-pronged fork, light enough to be used with one hand, for lifting seedlings; a larger fork for trenching alongside the rows and opening out the plants; a light handy spade for notching and for refilling the holes with soil; a dibble or planting iron for opening up the ground which has already been notched for the reception of the plants; a pick and mottoek, which may be combined in one implement, for use in stony or upon very hard ground.

In notch planting with small subjects, and upon very thin and light soils, a marker precedes the planter, and with a cross cut of his spade indicates the position of the tree. The planter afterwards drives his iron into the ground at one extremity of an arm of the cross-cut, presses down the handle, and thus opens the slit at the centre, into which the carrier pushes a plant, and the ground is afterwards closed by the foot. In this way from 1200 to 1500 small trees may be planted in a day by an active man and a boy. Wherever large plants are pitted in prepared holes, care should be taken to put them very little, if any, deeper than they stood in the lines of the nursery; and while the soil is being filled in, the holder should by a slight vertical motion of the plant settle the soil well under the roots and scatter these regularly throughout the soil. Where the soil is light and dry some treading may be necessary to steady the tree in its new quarters; but wet soils are best untrudged at the time of planting, though they may be subsequently rammed down and consolidated in dry weather. The collection of tree seeds will demand attention during the present month. Among the first trees to drop their seeds are the Norway Maple, the Walnut, the Birch, and the Sycamore; then follow the Alder, the Ash, Beech, the Chestnut, and the Oak. Where any of these are intended for planting during the coming season they should be put into the ground as soon as they fall; for unless they are properly harvested or sufficiently dried without artificial means being resorted to, few seeds afterwards germinate freely. None of them will keep well in boxes or bags, though they may be spread out to dry and kept well turned, or stowed away in dry earth, sand, or sawdust. A good loam is suitable for planting out Acorns and Chestnuts, and almost any deep and well-tilled soil will do for the Ash-keys.

Make and plant out cuttings of various kinds—Dogwood, Ribes, Portugal and common Laurel, Alder, Lime, Poplar, Plane, Willow, and Elder; also layer Maples, Elms, Limes, Rhododendrons, &c. Mark all trees for cutting down in mixed and ornamental planta-

tions, that the work may be commenced next month. Collect Hips, Haws, Yew and Holly berries, and commit them at once to the rot-heap. Dibble Acorns into all vacant spaces in Oak plantations, having first lightly pared off the surface and well stirred the soil.

Land recently cleared of timber and intended to be replanted, may at once receive a good trenching, so that all roots and remains of the former crop may be burnt up or cleared off. Nothing proves so injurious to the roots of young trees as old wood left to decay in the soil. As the nursery plots become cleared, have them well dressed with lime or compost, and roughly dug in preparation for the next crop of trees or vegetables. Strong layers may now be removed from the stools and planted out, and the stools dressed preparatory to future layering. Strong plants of Ash, Oak, and Chestnut, which will not go out for another year, may be undercut in the lines. October is a good time for planting young Hawthorn hedges upon fairly dry soils. Three or four years' old plants which have been twice transplanted, may be put in triangularly in a double row, and afterwards cut down tolerably close to the ground. By allowing these to grow freely for the first two years, and then trimming them back to within a foot of the ground, and afterwards switching the hedge once a year, leaving each time an additional 6 in. of growth at the top, and about 2 in. or 3 in. on each side, a strong and impenetrable fence may be obtained in about seven years from the time of planting.

A. J. BURROWS.

THE SCARLET BERRIED ELDER.

(SAMBUCUS RACEMOSA).

THIS fine shrub should be seen in its native habitat in order to form a correct idea of its decorative merits. Though it is met with growing freely in both British and Continental gardens, it rarely produces its clusters of fruit in such quantity as it does in a wild state. It is a true Alpine shrub, occurring frequently at an altitude of 4000 ft. to 5900 ft. on the Bernese Alps, where during the months of August and September—its fruiting season—it forms an object of great beauty. On the steep slopes of the Brunig Pass, and along the route from the lake of Brienz to the lake of Sarnen, at this season it keeps up a continuous display, and has the appearance in the distance of well-berried specimens of the Mountain Ash. It varies considerably according to the amount of nourishment which it receives; where the soil is poor, consisting for the most part of disintegrated rock and sand, the foliage is scanty and light coloured, and it bears small globular clusters of fruit; but where there is more fertility the foliage is luxuriant, and the clusters of fruit resemble miniature bunches of Grapes, measuring from 4 in. to 6 in. in length, with berries of a bright scarlet. It forms a large bush some 10 ft. to 12 ft. high, and about as much through with numerous arching branches, bending to the ground at the extremities, from which arise a number of erect ones, which in turn bend downwards as their laterals assume the erect position. The leaves have from five to seven elliptic-acuminate serrated leaflets, which when the plant is in a vigorous state are bluish-green above, and light glaucous green beneath. The flowers are greenish-white, and are borne in erect terminal and lateral racemes, which as the berries enlarge become pendulous. It differs from the common Elder in having a smooth dark bark with few fissures, in its more shrubby habit, narrower leaflets, racemose flowers, and scarlet fruit. It seems to thrive best when growing in a rich moist soil upon a rocky subsoil, and probably if the conditions under which it is found in its native habitat could be successfully imitated, it would become quite as effective an ornament in our gardens.

C. M.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Euonymus radicans variegatus as a Wall Plant.

—This plant covers a wall 12 ft. high in the gardens of Penrhyn Castle with its silvery foliage and shoots which cling to the wall like those of the Ivy, and yet it is only a short time since we knew it only as a dwarf trailing plant.

A Distinct Hardy Shrub (*Diplopappus chrysophyllus*).

—We noticed a considerable stock of this very curious and beautiful shrub in Messrs. Francis and Arthur Dickson's nursery at Chester, in which it has proved quite hardy. It belongs to the natural Order of Composites. All its branchlets, as well as the undersides of the small leaves, are covered with a golden dust or powder, somewhat like a golden Fern. It is a very desirable and distinct plant.

The Oak Leaved Hydrangea.—This is only occasionally seen, and regarded partly as a curiosity, but it really is a fine shrub. A very large specimen of it now in the gardens at Rhianna has many of its leaves a claret red, and of various shades. It is also in bloom, and in all ways is a remarkable shrub. In the same garden a specimen

of the *Hydrangea* with all the central florets perfect is very handsome, and in charming contrast to the ordinary form in which all the flowers are monstrous. In the perfect flowered form the heads are blue and pink, and that often on the same bush. How is it that this beautiful form is so seldom seen?

The Cut Leaved Elder.—Is this shrub enough grown? I passed a specimen of it the other day, which I mistook at first for a very fine specimen of the Japanese Maple, but Japanese Maples very rarely attain such a stature.—V.

Rhododendron virgatum.—This *Rhododendron* stands quite alone with respect to its early-flowering tendency. A large proportion of a batch of seedlings, only two years old, have bloomed freely this spring. It is a charming species, and one which should be useful for purposes of hybridisation.—T. SMITH, *Newry*.

Solanum crispum.—There are two shrubs bearing this name, at least in some places: one a dull purplish colour, and very inferior to the handsome blue bush we have mentioned as so beautiful at Glasnevin. The last winter and spring injured it, but a short time suffices to establish other strong plants.

Fraxinus concavifolia variegata.—This deserves a passing word of praise. The tree is somewhat upright in habit, and its growing points are always variegated with white, making it look in the distance as if it were covered with white flowers.—T. SMITH.

St. John's-wort an Enemy to Trees.—An undergrowth of St. John's-wort has caused the death of a variety of well-grown trees at Penrhyn Castle. It is such a vigorous and constant grower that all the moisture needed by the trees goes to the *Hypericum*.

Eurybia gummosa.—On a wall this has proved to be quite hardy, and it has been completely covered with pretty white Aster-like flowers, which are also delicately scented. The specimen in question is about 4 ft. by 3 ft., and when in blossom it was very conspicuous.—T. SMITH, *Newry*.

Spiraea japonica in the Wild Garden.—Mr. Ellam planted out some spare stock of this in a wood at Bodorgan, and with the happiest effect. The plant grows and flowers freely, the flowers appearing a fortnight later in the moist cool wood than on plants of the same kind on a north garden border; therefore they prolong the season of this favourite flower. They are planted in an irregular group, as such things should generally be, the effect being much better than that obtained by the common dotting plan.

Draining Bog Land by Planting.—The following is a successful and profitable method of effectually draining bog land: Upwards of forty years ago Mr. Murray, then land agent to the Earl of Jersey, planted a bog near the Button Ferry Station, South Wales. This bog was quite useless and even dangerous, as people often lost their cattle in its wet quagmires. Mr. Murray planted it with Black Italian Poplar, which we supplied, and the trees made such extraordinary growth that at the end of fifteen years, when they were cut down, the produce realised something like £13 per annum per acre for the whole period of fifteen years during which the crop had occupied the ground; it luckily happening that the poles were just wanted in the neighbouring copper works. However, this was not all the benefit or profit derived from planting the bog with these rapid-growing trees. Their strong roots running through the underlying clay thoroughly drained the bog, letting off the water in a way that no other process of draining could accomplish. Beneath all bogs, which are formed of decomposing vegetation, there lies a bed of clay, and below that comes a bed of gravel. The strong roots of the Poplar will run down through the soft bog to a depth of many feet, and pierce through the bed of clay some feet thick into the gravel. In these days of great demand for packing cases, &c., the wood of this Poplar is very valuable, and the tree has the additional property of arriving at a fit state to be cut down in a man's lifetime. When the timber was removed, a charge of gunpowder was inserted in each stool, which effectually burst them up and rendered their removal easy. After the ground was cleared, a beautiful rich, firm pasture remained.—WM. MAULE & SONS in "Journal of Forestry."

Canadian Forests.—The soil of the eastern townships is very fertile and susceptible of the highest degree of cultivation. The features of the country are rolling, having the appearance when viewed from an elevation of an upheaval of an immense wave suddenly stilled; and these slopes and valleys, before they were cleared, were covered with a luxuriant growth of those kinds of forests which in America are known as a sign of naturally drained soil and great fertility. There are many kinds of wood found in the eastern townships forests. Among these the following may be enumerated: Maple (hard and soft), Birch, Elm, Ash, Spruce, Bass wood, Butternut, Hickory, Cedar, &c. It is also to be noticed that contiguous to these woods are numerous water powers which may be utilised in manufactures. The country is literally intersected with streams and rivulets, the waters of which are cold and clear and the home of

the red trout. In the north-west territory of the province of Manitoba nearly the whole of the fences are composed of posts of Spruce and Poplar, the latter of which, with the bark removed, will last twenty years. Pine and Bass wood lumber are also used, the former ranging from 20 dols. to 60 dols. per 1000 ft. Poplar and Oak are in sufficient quantity to supply the present demand, but I fear there is not enough to supply a very large population, in which case there might be a scarcity of Bard wood, but plenty of Poplar and Tamarac, the former of which is reproduced very rapidly. Coal is not known to exist in the province of Manitoba, but is said to be found about thirty miles west of the boundary of the province. In the Peace River country five-sixths of the timber is Poplar. Balsam Poplar is very abundant on the islands in all the north-western rivers, often attaining a diameter of from 6 ft. to 10 ft. White Spruce grows to a very large size on all the watersheds and the slopes of the south bank of the Peace River, on islands in all the rivers, and very abundantly on the low lands at the west end of Lake Athabasca. I have often seen it over 3 ft. in diameter, but the usual size is from 1 ft. to 2 ft. White Birch is not abundant along the Peace River, but is common on the Athabasca and Mackenzie Rivers. The Northern Indians make large quantities of syrup from its sap in spring.—A. J. B.

Effect of the Late Season on Forest Trees.—Enough has been already said about the deficiencies of almost every kind of autumn fruit, but I have seen little reference to forest trees. Here, near the sea coast in Cornwall, I observe that the foliage is fairly good on Ash, Beech, Elms of several sorts, Horse Chestnuts, and Lime; whilst it is very small and stunted on English and Turkish Oak, Spanish Chestnut, Plane, Poplars (various), Alder and Walnut. Scarcely any Acorns are to be seen even on young and vigorous Oaks, and where they occur, they are so small, that fifty Acorns in their cups, freshly picked from a healthy Oak of about thirty years' growth in a sheltered and sunny situation, (pedunculate?) weigh less than one ounce and a half; whilst the largest I can find among 300 Acorns is only $\frac{3}{4}$ in. in length with its cup. All Conifers seem to have suffered also, though in a less degree. The season of 1784 seems to have been very similar, for I find Dr. Johnson thus complaining to a friend, in a letter dated August 26, 1784: "Is not this strange weather? Winter absorbed the spring, and now autumn is come before we have had summer. But let not our kindness for each other imitate the inconstancy of the seasons."—J. J. R., *Penrose, Hilston.*

Suitable Trees for Smoky Climates.—In parts of the country where most kinds of trees are perishing from the effects of smoke and deleterious gases given forth by the factories, there are two species of trees that seem absolutely unaffected by them, and these are the Sycamore and the Spanish Chestnut. At one place near Sheffield, where there are extensive manufactories of coal and iron works all round, most of the trees are either dead or dying, especially the Oaks and Firs, but not the Sycamores. Within the last twelve years a group of these trees has sprung up naturally where other species are dying, and have grown quickly to the size of trees, and are thriving amazingly, visibly laying wood on the trunk every year. And it is the same all over. Seedlings spring up everywhere, and have to be extirpated in places where they would do injury by crowding other things out. The Spanish Chestnut is just about, if not quite, as vigorous as the Sycamore, and trees perhaps 100 years of age, or a little under, do not show a dead twig, while young ones soon grow up and ornament the landscape. Of the value of these two trees for timber I cannot say much, but I suppose they are both extensively enough used to pay for their culture in places where more valuable trees will not thrive, and they have the advantage of being rapid growers and coming early to timber size. Another tree which may be observed springing up naturally, and in great abundance, where the Oaks have perished, is the Birch. In some tracts in the woods here the Birch bushes form quite a thicket, and look healthy and growing, though exposed to the same influences that are killing or injuring their neighbours. While speaking on this subject, it may not be inapt to remark that one of the worst features of English woodcraft is the leaving of so much dead and dying timber standing, while cutting down trees annually for sale which are healthy, and the removal of which is not urgent. On plenty of estates the quantity of timber left to decay of its own accord is quite prodigious, and it never seems to occur to the woodman to cut it down and turn it to account while he may, unless it be such as happens to be included in the "annual felling" on some portion of the estate. Crowding of old but healthy trees is another evil. Sometimes they are left to stand through the aversion of the owner to their being cut down, but often they are left through neglect. Thousands of pounds worth of good timber might be removed from estates where it would never be missed, and at the same time greatly relieve the trees that were left by giving them more room and light.—C.

PLATE CC.

RHODODENDRON KATE WATERER.

Drawn by MRS. DUFFIELD.

THIS variety, which was raised at Bagshot by Mr. John Waterer is certainly one of the most beautiful and distinct Rhododendrons which have been introduced for some time. It possesses, as will be seen, fine foliage, is of good habit, free flowering, and thoroughly hardy, qualities which render it most desirable in any situation in which it may be placed. It is the custom at Bagshot to cross all the best kinds, collecting the seeds indiscriminately, and sowing all together, therefore it is impossible to say with certainty from what source this variety originated. Its colour is distinct and bright, and the spotted yellow blotch sets off the flowers to increased advantage. The following excellent Rhododendrons have also been raised within the last few years by Mr. John Waterer, viz., Duchess of Bedford, Lady Tankerville, Bai Waterer, Mrs. Arthur Walter, Baron Schröder, B. W. Currie, John Walter, W. E. Gladstone, and Jack Waterer, all kinds worthy of being added to any collection.

DOUBLE AND SINGLE FLOWERS.

BOTANISTS put little value on double flowers, however attractive in appearance they may be, looking upon them as simply abortions, and in this they are consistent, for their estimate is taken from a natural stand-point, double flowers being merely the result of high cultivation, which, when continued through successive generations of plants raised from seed, often results in the flowers undergoing a transformation in the organs of reproduction. On the other hand, this condition in plants is looked on by florists very differently. With them the majority of double flowers are held to be improvements, coming nearer to the standard which they, the florists, have set up, and which has generally, even outside their body, been accepted. Again, the duration, that is, the time a flower will last, is a matter worth taking into account, by the majority of cultivators, as there is no doubt that double flowers possess the advantage of lasting considerably longer before they fall than such as are in a natural state. Yet the subject presents itself in another light. The greater number of flowers when they become double lose much of their simple beauty and elegance. Take, for instance, the double-flowered Anemones, Fuchsias, Pelargoniums, and Petunias, and the last to make their appearance, double Begonias, in all of these the eye has not become so used to see the double forms alone as to lead people to forget the attractions of the flowers in their single state. Even Roses that we have been so long accustomed to see held in estimation proportionate to the extent of the doubleness of their flowers, no one can hold that from a purely artistic view these are nearly so beautiful as the flowers that are much more single. The looser-flowered Tea varieties, for example, although a further amplification of their petals would perhaps improve them for exhibition purposes, yet it would have a contrary effect as flowers for the many. These views were further impressed upon me from a sight of the beautiful single Dahlias that have within the last year or two been brought under notice, after being all but lost sight of except with the comparatively few individuals who look upon the merits of a flower apart from the fashion of the time being. So far from the cultivation of plants, when carried in the direction of producing their flowers in a double state being a desirable consummation, I look upon it, with few exceptions, as a step in the opposite course. T. BAINES.

Paraffin and Woolly Aphis.—I should have been equally unwilling as Mr. Douglas to try this, had it not been recommended to me by so experienced a horticulturist as Mr. Llewellyn; and with the assurance that he thought his plants were rather benefited by it. It was said in the hearing of one of our most distinguished vegetable physiologists, who stated that from its chemical components he could quite understand this. I do not find that the roots of my plants so treated have suffered in the least, and unless Mr. Douglas can back his warning by some valid reasoning, I do not think it is of much value. I do not see much connection between an untidy garden (which I am sorry to say mine is) and an inability to grow florist's flowers; in fact, it might be put the reverse, that the owner's time is so occupied with these that he had no time for the other; but the truth is, "it is my poverty, and not my will consents." Were I a head gardener, with any amount of labour at command, I might keep my garden as neat as Mr. Douglas does his, but being only an amateur, who does a good deal of his garden himself, the weeds must sometimes have their way; and indeed this year if everyone who allowed weeds in his garden was to be set down as inefficient, it would seal the doom of many a horticulturist.—DELTA.

RH. I. DENLON FATS WATERER

GARDENING FOR THE WEEK.

Flower Garden.

Owing to falling leaves, worm-easts, and decaying flowers it is now difficult to maintain neatness in ornamental grounds, but, as no enjoyment can ever be derived from an untidy garden, an effort should be made to do so. The scythe, lawn mower, roller, and broom will need to be kept going daily, and, though the ground may not continue long tidy, we shall have the satisfaction of knowing that we have done our duty as far as endeavouring to maintain neatness is concerned. The finer weather which we have had during the last two or three weeks has infused a degree of brightness into the flower beds that has not been exceeded the whole season, and this we must try to keep up as long as possible. Tender plants that are to be preserved for stock another year, and which cannot yet be lifted, ought to be covered up with some light material every night; tiffany, hexagon netting, or Frigi Domo, are all excellent materials for the purpose. The season has been of such an exceptional type that those bedding plants that have succeeded well in spite of bad weather should have the greatest prominence, and with this intent I name the following, all of which have been exceptionally good, viz., *Ageratum* Cupid, *Tropeolum Lobbianum* Perfection, *Tropeolum Bedford* Rival, *Lobelia* Brighton, *Viola* Blue Bell, *Verbena* Purple King, and *Mesembryanthemum* conspicuum. Of flowering Pelargoniums the following sorts have stood all weathers best, viz., *Vesuvius*, *Bonfire*, *Happy Thought*, *Master Christine*, *Nora*, and *Waltham* Seedling. Plants with the brightest foliage have been: *Mesembryanthemum cordifolium* var., *Veronica* incana, *V. repens*, *Kleinia* repens, *Echeveria* secunda glauca, *Sedum* acre elegans, *S. glaucum*, *Herniaria* glabra, *Mentha Pulegium* gibraltaria, *Gnaphalium* lanatum, and *Pelargonium* Manglesi variegatum, and *Crystal Palace* Gem. *Pyrethrum* Golden Feather has for the first time failed to be satisfactory; the excessive wet has caused it to damp off. The superiority of leaf arrangements over beds of a flowering character has been most marked throughout the entire season, and still continues to be so, and if we could but find a substitute that would give us the colours of the tender *Alternantheras* we might almost defy our fickle climate, and yet have effective beds, not only throughout the spring and summer, but during the entire year, provided a little supplementary planting of small shrubs, &c., at the end of the bedding season was carried out. The following are amongst those that are most suitable for this purpose, viz., *Retinosporas*, small variegated *Hollies*, variegated *Euonymuses*, the dwarf *Thujas*, *Cypresses* and *Junipers*, variegated *Yews* and *Aucubas*, *Heaths*, *Japanese Honeysuckle*, and *Periwinkle* (*Vinca elegantissima* variegata). The propagation of plants for another year will still require attention; of course all the more tender kinds ought to be in safe quarters, as frost may visit us at any time. *Calceolarias* and *Violas* will now strike freely and winter well—indeed best—in a cold frame. Hardy plants may be divided and pricked out on a dry bank. *Mentha Pulegium* gibraltaria may thus be safely wintered, but if left thick on the ground as it now stands it will succumb to damp, as will also *Cerastium tomentosum* and *C. arvense*. Contemplated alterations and improvements may now be carried out. All such works should be taken in hand early in autumn in order that they may be completed before the busy spring time interferes with their further progress. Walk making, turf laying, and levelling, draining, grubbing, and trenching, and shrub and tree planting, are some of the operations that are best and most conveniently done in the autumn and winter.—W. W.

Auriculas.—If either seedlings or named varieties growing well are in pots that are not considered to be large enough for them to flower in, they had better be potted, although it is getting late in the season for that to be done. Such late-potted plants, should, however, have no surface dressing in February. We find slugs very troublesome, and the only way in which they can be destroyed is taking pains to catch them at night under lamplight. Seedlings are now coming up rather freely, and it is necessary to be careful with regard to giving water; just allow sufficient to keep the soil moist. Many keep their plants on a cool bottom during the summer; but this is just the place in which worms are likely to get into the pots. I generally set them on trellis-work, in order to keep out the worms; but if they do get in, the best plan is to turn the plants out and search for them. It would be much better for the plants to shake all the soil from their roots than it would be to allow the worms to remain in the pots.

Carnations and Picotees.—No time should now be lost in getting off layers and repotting them. Instructions as to this matter have been previously given (p. 288). See, too, that slugs are not allowed to prey upon the leaves of those that have been layered in the open ground; the leather-coated grub also eats the leaves greedily, and should be looked for at night. Rabbits are likewise remarkably fond of the leaves. Tree Carnations now re-

quire considerable attention; the plants must be removed under glass, and the stems carefully tied to sticks. Those that have not been repotted should be seen to at once. It is easy to err on the side of too large pots. Those used here are from 6-in. to 8-in. A very large plant can be grown in an 8-in. pot, and such a plant will produce a very large quantity of flowers. When the pots are well filled with roots, and it is seen that the plants lack vigour, weak manure water can be supplied to them—say about once a week.

Hollyhocks.—Seedlings may be planted out in their permanent quarters, but before doing so see that the ground is in good condition. Perhaps there are few plants that can assimilate so much gross food as the Hollyhock, and to have good results from seedlings the ground should be deeply trenched, and have at the same time plenty of rich manure worked into it. When the spikes are exhausted they may be cut over near the ground, and the roots may be lifted at once, or allowed to remain for a few weeks as it may be convenient. The commoner varieties can be planted out close together in a frame, but scarce, choice sorts had better be potted for the convenience of placing them in a warmer house early in January, with the view of obtaining cuttings from them. Until that time they may be kept in a cold frame.

Pansies.—If it is intended to flower any of these in pots no time should be lost in getting them potted into 3-in. ones. Place them in a frame quite close to the glass, and draw the lights off them both day and night, while the weather is favourable, as the heavy dews on calm nights are beneficial to them.

Polyanthuses.—If these are not potted let it be done at once. "A. D." (p. 285) misunderstands what I said about potting. He says I "favour the growing of these in pots large enough to enable the plants to carry several trusses, a course different from that acted upon by the old northern florists." It is they who use large pots (7-in. ones) to produce one truss. I advocate the use of 5-in. pots, which I consider large enough to produce and bring to perfection four and five trusses of bloom. Leaf-mould may be added to the compost, although I cannot agree with "Broekhurst" (p. 286) that it is the "natural soil for both Polyanthuses and Primroses." Who ever found them growing wild in leaf-mould?

Primulas require putting right for the winter. Most of them succeed well under the same treatment as that given to Polyanthuses and Auriculas. Strong growing species such as *P. denticulata*, *purpurea*, *Cashmeriana*, *rosea*, *Munroi*, *luteola*, *sikkimensis*, and a few others may be potted into 8-in. pots, and the smaller growing sorts into 4-in. or 6-in. ones. Some varieties are much more attractive to slugs than others, and these pests often do much damage if great watchfulness is not exercised to keep them in check. The pretty little *P. minima* and *glutinosa* seem to afford the best feeding ground for them. I place the plants in frames along with the Auriculas, and in all respects the instructions given for them apply to the Primulas.

J. DOUGLAS.

Orchids.

At this season the plants, especially the intermediate heat requiring species, and also the cool section, will need to be differently treated. *Cattleyas*, such as the different varieties of *C. Mossie*, *C. Aelandia*, the various forms of *C. Triane*, *C. bulbosa*, and *C. Warneri*, that bloomed in the early part of the spring, will by now have completed their growth, and to prevent their pushing afresh must be kept considerably drier at the root; but I would caution beginners in their cultivation to always be careful not to completely withhold water too soon, that is, before the pseudo bulbs have got to their full size, and attained that stout plump condition present when they receive the requisite treatment. Where the application of water to the roots is not continued long enough, the result is, that the season's growth does not produce anything near the full complement of flowers, rarely breaking strong, or making double growths the ensuing spring in the way common with vigorous healthy plants. Examples of the above that have flowered later, as also of the two-leaved kinds such as *C. guttata*, *C. intermedia*, *C. Loddigesi*, *C. Skinneri*, and others of like habit, must for some time yet have sufficient root moisture to keep them on until growth is finished. The autumn blooming *C. labiata* with *Lælia Perrini* will now have their flowers pushing up inside the sheaths, and require to be in a temperature such as is necessary for the kinds that are growing, keeping the roots slightly moist.

Lælias of the *purpurata* and *elegans* sections require to have the treatment similarly varied according to the stage of growth they have arrived at. The autumn blooming *L. aneeps* and *L. autumnalis* will be pushing up their flowers to assist the development of which the temperature of the intermediate house will be necessary, at the same time remembering that the slower they are brought on, provided there is enough warmth for the healthy development of the flowers, the longer the individual blooms will last.

Cœlogynes.—*C. cristata*, *C. fimbriata*, *C. Gardineri*, and other species requiring similar treatment should be liberally supplied with water, and kept on growing until their pseudo bulbs have reached their full size.

Dendrobiums grown in the same house will need even much more diversity of treatment as to moisture at the root in accordance with the condition of growth they may be in. It is highly necessary also in the case of these, which are essentially water-loving plants during the time of their growth, that the pseudo-bulbs should be quite plump before they are kept dry at the roots; yet if water is continued too long most of them have a disposition to commence growing again, which is anything but desirable unless in exceptional cases, such as of small plants, when instead of managing them with a view to producing flowers, it is looked upon as more advisable to allow them to make a second growth, which may be kept on slowly moving through the winter, although this course is often a questionable gain. The different forms of *D. Wardianum*, *D. nobile*, *D. Schröderi*, *D. pulchellum*, *D. Pierardi*, *D. moniliforme*, *D. heterocarpum*, *D. Farmeri*, *D. Falconeri*, *D. chrysotoxum*, and many others requiring similar treatment, must, as their growth is completed, be reduced to a perfectly dry condition of the roots, but keeping them in the house in which they have been grown until their growths have time to get well ripened, a condition upon which their flowering much depends. All such plants that are approaching a state of rest should be placed, so far as possible, at the coolest end of the house, keeping the warmest end for those that have yet some growth to make.

Oncidiums and Epidendrums, along with Schomburgkias, *Trichopilias*, *Zygopetalums*, *Cymbidiums*, *Bolleas*, *Brassias*, *Barkearias*, and others wanting a like temperature, require close watching, especially by beginners, in their cultivation, so as to withhold water at the right time from the plants as they complete their growth. More observation is necessary as regards this matter at this time of the year than at any other by reason of the need for yet keeping up a moderately brisk temperature for the many plants that will still not have finished growing.

East Indian House.—Those species of *Dendrobiums* usually grown in a high temperature, as the different forms of *D. macrophyllum*, *D. fimbriatum*, *D. Griffithianum*, and *D. chrysotis*, with *Cattleya superba* and other Orchids that form pseudo bulbs and require a temperature such as the East Indian house, must have water withheld as they finish their growth. The greater portion of the occupants of this warmest department, comprising most of the species of *Aerides*, *Saccolabiums*, *Vandas*, *Phalanopsis*, *Limatodes rosea*, *Sarcanthus*, *Galeandras*, *Bolbophyllums*, and *Angræums*, will not yet have their growth completed, and should be treated to a sufficiently high temperature to keep them growing freely, but by no means err in keeping them too hot, especially in the nights now fast lengthening; better be content with slower and less growth than to over-stimulate the plants by too much heat. Keep all according to the respective requirements of each sufficiently supplied with moisture at the roots, but reduce the atmospheric moisture proportionately with the diminished sunlight. In respect to this latter, moisture in the atmosphere, those amongst Orchid growers who have through this exceptionally sunless summer proportionately restricted the amount they have used all on through the season, will have their plants in a more satisfactory state, with a view to the endurance of the foliage and continued healthy condition, than where the ordinary routine has been followed of a fixed course of treatment during the growing season, independent of the kind of weather we happen to have.

Cool Orchids.

Odontoglossums, in like manner, will, as a rule, need to be treated in accordance with the state of growth they are in. Although plants that do not require nor can bear drying at the roots to the extent that many species will, even when their growth is finished, still they are better with their roots in a drier condition than when active growth is going on. Let those that are in full growth have sufficient root moisture, with enough air to keep the atmosphere of the house fresh and sweet; but I should advise the ventilators, or other places where air is admitted, being closed on all nights when there is a likelihood of the temperature running low, as although so much is frequently said about these plants bearing all but being frozen, still no possible good can come from subjecting them to such treatment at any time, and more especially whilst growing.

Masdevallias, *Epidendrum vitellinum*, *E. aurantiacum*, *E. erubescens*, such *Lycastes* and others as are grown in the *Odontoglossum* house, will in cases most be benefited by now being kept at the warmest end and supplied with root moisture in accordance with their more or less advanced state of growth.

Shading.—In each of the departments, hot, intermediate, and cool, the shading should now, so far as possible, be dispensed with,

only running down the blinds when the sun happens to be bright. Where the *Odontoglossums* are grown in a lean-to house with a north aspect there will be no further need for any shade at all.

Ferns.

Where separate houses exist for the cultivation of the species of Ferns that require more or less artificial heat to grow them, it often happens from the absence of their needing, as in the case of flowering plants, treatment to ripen and mature their growth, that they are kept on growing through a greater portion of the year further than is necessary, and also that considerably more heat is frequently used than is beneficial. The confused mass of over-lengthened fronds the plants often make, both under pot culture and when planted out, necessitating a frequent reduction in the number grown, and thereby diminishing the interest attached to the collection, is frequently as much traceable to over-excitement by the use of more heat than is requisite, as it is to another cause which I have before referred to, that is, too much root-space. Another result of over-much warmth accompanied by a too confined atmosphere is that although the fronds, whilst in their younger stages have a fresh and luxuriant appearance yet through the winter and up to the time of growth in spring taking place, they lose colour and become much more unsightly than when grown cooler. Ferns more than any plants we grow should always be confined to such conditions in their cultivation as are calculated to ensure a stout, comparatively short, robust state of the fronds rather than undue extension. Not only is this essential for the general appearance of the plants from a decorative point of view, but also for the purpose of intermixing with flowers in the various ways they are employed, as growing Ferns in the manner which renders them the most durable for cutting is equally worth consideration. Although the strong-growing kinds with large fronds are generally not so much used for cutting as the *Adiantums*, *Pteris*, and similar small-growing species, yet there are many of the larger growers which have more or less elegantly sub-divided fronds, that where large vases and other similar arrangements of cut flowers are needed not only give variety, but are better adapted than the small-growing species alluded to. With a view to securing these conditions, I should advise Ferns, where grown in houses by themselves principally, being now through the autumn treated to considerably more air, accompanied by a drier state of the atmosphere, as well as dispensing with shading, which will have the effect of discouraging further growth, and will also help to solidify the fronds that are already made, but this is as far as it is safe to go in this direction, for the nature of Ferns is such that they will not bear the soil in which their roots are placed being allowed to get dry without more or less disfiguring the fronds, a result that has invariably followed attempts made by some growers of submitting some species to the dry state of the soil which they were naturally subject to in their native countries, but which the very different condition of their growth produced under cultivation makes them unable to bear. Ferns are admittedly very easy plants to grow, but to have them in the state which admits of their retaining a fresh handsome look through the dormant period, they need to be treated during the summer and autumn in a way that gives the most endurance to the fronds. It is scarcely necessary to say that the clear manure water that has been advised to be given through the growing season to those plants that are confined in small pots with little root room, should be now altogether discontinued until the time for growth commencing again comes round, substituting clean water in its place. In the case of Ferns, as with other cultivated plants, in addition to the vigilance necessary to check the quicker breeding kinds of insects as they make their appearance, such as aphides, it is well from time to time to go over all the occupants of the house to free them from any of the more persistent species like scale, mealy bug, or thrips; and if at the same time all unsightly fronds are removed, and the pots washed clean, it adds much to their appearance. It is through the dormant season now beginning that insects of all kinds can best be got under with a view to reducing the labour necessary to keep them down, whilst the plants are in active growth, at which time insect life is also most active.

Filmy Ferns.—These exquisitely beautiful plants were at one time considered very difficult to cultivate, an impression that no doubt originated through their failing to thrive when grown in the warmth usually applied to the heat-requiring kinds. But they are just as easy to manage as the generality of other Ferns when treated in accordance with their requirements, and there is no doubt that many species of *Hymenophyllum*, such of the *Trichomanes* as reniforme, *pyxidiferum*, and the different varieties of *T. radicans*, along with the charming plume-like fronded *Todeas*, may be grown by any one who has an ordinary greenhouse, or they will even do in a cold frame, as in several parts of the kingdom, north as well as south, numbers of full-sized beautiful specimens were kept successfully through the last severe winter without any artificial heat, and no

protection beyond a few mats not sufficient to keep them from being frozen through both fronds, and a considerable portion of the soil which contained their roots. Plants so subjected show no further injury from the cold they have been submitted to than a partial disfigurement of their old fronds, and have grown freely during the summer. To those who have not had any experience in the cultivation of these plants, it is necessary to point out that although nearly hardy their nature is such as to render their existence impossible where the atmosphere that surrounds them is not to a considerable extent saturated with moisture; consequently it is useless attempting to grow them in frames along with other plants, as it is needful to keep them all but closed with a view to avoid the drying influence of the external air. They must always be kept moist at the roots, and the bed of coal ashes on which the pots during the summer ought to stand, and in winter be plunged, must likewise be kept moist. The light also needs to be much subdued by tolerably thick shading when the sun comes at all upon the glass, as well as smearing the glass with thin green colouring during the summer months. If grown in a greenhouse with other plants they should occupy the most shady position in the house, placed on the floor enclosed within an ordinary frame or glass case made for the purpose, and also shaded when the weather is such as to require it. Single plants of *Tokeas*, the hardier *Trichomanes*, and *Hymenophyllums*, do very well in rooms where little fire is used, especially near windows with a northern aspect, as a matter of course covered with bell-glasses, or in glass cases, and kept moist. So treated, with the little attention which they at all times require, they will go on increasing in size for many years, and are most interesting.—T. BAINES.

Hardy Fruit.

The harvesting of Apples and Pears now requires daily attention; our rule is to devote a couple of hours every fine afternoon to such work, carefully examining every kind, and gathering only those that part readily from the tree, or that the birds or wasps have attacked, the latter especially being no mean judges, both of quality and maturity; the birds are not such infallible judges, for Tomtits will attack all and sundry, if left unmolested, so that the birds must either be destroyed or the fruit must be netted up. Pears have increased in size marvellously during the last three weeks, and the latest kinds are still swelling fast, so no undue haste should be made to gather them; indeed most of them will need to be left on the trees till there is danger of injury from frost. As soon as the fruit is gathered all trees that have borne heavy crops or that seem weak from exhaustion should have the surface soil cleared away from about the roots and replaced with fresh compost, consisting of loam, with a slight proportion of lime scraps, and charcoal intermixed, the whole to be made firm about the roots, and then mulched with good stable-yard manure. If such dressings could be given to free-bearing fruit trees every autumn we should have little cause to complain, either of size or quantity of fruit, this at least is our experience, for on trees that have been regularly dressed we have never yet failed as regards having plenty and fine fruit, and the present unfavourable season is no exception to the rule. This month is also the best time to root-prune all trees that require a repression of growth, in order to make them more fruitful. Young trees that have not been planted more than three years had best be lifted entirely; their strong roots should be shortened back, and any that have been injured by digging them out should be cut clean off. The trees should then be replanted in the same soil. Large or older trees may have their roots bared, a trench cut out a few feet from the stem, and all the roots met with in the trench cleanly cut off, after which refill the trench, ramming the soil as firmly as possible, thus causing a certain amount of resistance to be encountered by the roots, which will conduce to the formation of numerous small branching rootlets that are of much more importance than strong non-lateral roots. For any new plantations that are to be made, the ground should first be thoroughly drained, and in heavy retentive soils each tree should have a few inches of additional drainage in the form of brickbats, charcoal, and mortar-rubbish. Of course, on gravelly or sandy subsoils such drainage is not required, and the trees may be planted level with the ground-line, but on heavy soils a slight elevation or mound is desirable. If the weather be favourable, and the ground in good working order, the end of the present month is the best time for planting all the following kinds of fruits, viz., Apples, Apricots, Peaches, Pears, Cherries, Plums, Gooseberries, and Currants. Clear runners off old plantations of Strawberries; lightly point over the surface-soil, and redress with good rotten manure. Young plantations should also be kept clear of runners, and those that are fruiting should be carefully protected from heavy rainfalls by means of handlights or frames. The plants of *Vicomtesse Héricar de Thury* that were planted out after forcing are now fruiting as freely as at the proper Strawberry season.—W. W.

Parks and Open Spaces.

The wet weather has kept grass in a continually growing condition, rendering mowing and rolling frequently necessary to maintain it in good order, and as it will probably grow rapidly for some time to come, I would advise that although mowing should still be frequent, rolling should only be done when the surface is in a comparatively dry state and not as hitherto when wet. The grass will be much benefited by allowing the soil to become partially dry before rolling, as whilst it is very necessary in summer to assist in retaining moisture it would now be injurious in preventing free evaporation, more especially on damp and cold soils. Grass seeds should be sown at once on bare places, or where the sward is thin and poor, choosing dry weather for the work; the quantity sown may be from one to two bushels per acre; in the case of bare places the surface should be broken up about an inch deep, adding soil if necessary where the grass is weak; a dressing of rich soil will be very beneficial; after the seed is sown the surface should be thoroughly bush-harrowed and finally rolled. A dressing of soot, salt, and lime during the month will greatly assist in destroying injurious insects and act as a fertilizer. This work will be especially necessary upon cricket and croquet grounds which have been much used during the season. Where very large spaces have become bare, turfing is the most desirable and expeditious method of dealing with them. The advantage gained by doing this work at the present time is that should we experience a favourable winter the grass will be stronger and therefore resist wear in a greater degree than if done in the spring; during the operation grass plots should also be freed of weeds as far as possible. The month of October is an excellent time to commence the re-arrangement of shrubs, a work which becomes periodically necessary in consequence of some varieties overgrowing others, over-crowding, losses, and other causes. Care and judgment must be exercised in order that a natural arrangement may be maintained, mixing the various kinds of foliage harmoniously, and having special regard to the different heights the shrubs are likely to attain. Should we be fortunate enough to have fairly dry weather during October and the early part of November, the soil will work very much better than later on in the year; nor are we likely to have very hard frosts during that period. If ordinary care be exercised not to injure the roots, and the shrubs are planted immediately after being taken up, they will in no way suffer from the effects of transplanting. New subjects may be added as required at the same time. Advantage of the season should also be taken to commence preparations where it is intended to form new plantations; the sites for these should be trenched not less than 3 ft. deep, taking care the bottom of each trench is well broken up. By so doing, great benefit will result to trees and shrubs; it assists drainage, and allows the roots to descend freely. Generally, however, the sites for plantations are more or less raised by carting soil upon them, in which case deep trenching is unnecessary. The surface should always be broken up before placing the soil thereon. Where the soil is very poor, manure should be trenched in or mixed with the soil; the manure must not be buried too deeply, 6 in. beneath the surface being quite sufficient, as it should be borne in mind that the benefit is derived from its gradual decay, the soluble portions being carried down by rains to the root in a condition most suitable for its absorption, whilst it maintains the surface in an open and healthy state.—C. DENNIS.

Extracts from my Diary.—October 1 to October 7.

VEGETABLES.—Earthing up Celery when dry. Tying and stopping Cucumbers. Trenching ground and otherwise preparing it for Cabbages. Hoeing amongst Spinach. Cutting fresh Mushrooms from bed spawned on September 3. Trenching border for Cauliflowers. Planting Potatoes in boxes, and placing them in Mushroom house. Digging south border for Lettuces. Manuring and trenching borders for spring cropping.

FRUITS.—Thrashing Walnut trees, and laying the nuts in heaps to cause them to shell. Looking over Muscat Grapes, and cutting out shanked berries. Placing boards under Melons swelling and fertilising their flowers. Sweeping the leaves off Peach trees with the view of assisting the wood to ripen. Getting pot Vines out of house, and nailing them on a south wall to harden them off before starting. Gathering remainder of Pears, viz., Glou Moreau, Beurré Rance, Easter Beurré, Bergamotte d'Esperen, Uvedale's St. Germain, Catillae, Ne Plus Meuris, Napoleon, Eyewood, and Chaumontel and Sturmer Pippin Apples. Surfacing and top-dressing pot Vines. Storing Walnuts packed in sawdust away in barrels. Looking over Apples and Pears in fruit room. Pruning first batch of Red Currants on border. Thinning superfluous shoots from Melons.

FLOWERS.—Taking Iresine and variegated Pelargoniums into the greenhouse for the winter. Re-arranging plant houses. Tying Stephanotis and Allamandas to roof of stove. Staking Poinsettias,

and placing them in stove. Also staking Mignonette. Weeding border on which are Stocks and Pyrethrums for spring bedding. Moving Primulas from pits and frames into warmer quarters. Taking shading off houses, and storing it away in sheds when perfectly dry. Taking Eucharis amazonica from pits, and placing them in stove for flowering.
R. GILBERT.

ASPARAGUS CULTURE.

(Concluded from p. 250.)

THE ASPARAGUS GROWER'S CALENDAR.

January.

Culture in the Open Ground.—Finish manuring the trenches which have not received their proper share earlier in the season, and level the mounds. Prepare the ground for fresh plantations in the spring, and finish the hoeings and diggings in those places where the trenches are to be opened at the end of the month.

of forced Asparagus if you have not already begun to do so in January.

Forcing in Heat.—Keep warm those beds intended to yield at the end of February and the beginning of March.

March.

Open Ground.—Continue planting in dry situations, beginning only at the end of the month in damp soils. Begin to earth up at the end of the month those heads which show signs of appearing. Earth up in the trenches to a depth of 2 in. or 3 in. if you have not done so in February. Begin cutting the early varieties.

Frames in the Open Ground.—Take away the frames and stable manure towards the end of March. Empty the trenches and fill them with soil.

Forcing in Heat.—Towards the end of the month break up the beds, the open-air culture taking the part of forcing in heat.

Fig. 1.—Bun-ling Machine.

Forcing in the Open Ground.—The beds of the first season are nearly exhausted by this time; we must therefore prepare others, so that we may have Asparagus in January, February, and beginning of March. On days when the sun shines we must uncover the frames; if the weather is cold increase the quantity of stable manure, and, if necessary, put some inside the frames.

Forcing in Heat.—Make new beds for Asparagus to be gathered at the end of January and the beginning of February.

February.

Open Ground.—Begin planting in dry situations, and open up trenches in moist ones, so as to expose the soil to the action of the air. Manure those soils which have become poor with well-rotted stable manure, artificial manure, ashes, composts, &c., and replace the soil dug out before the winter sets in.

Forcing in the Open Ground.—Continue the work of the preceding month, and begin gathering the second batch

April.

Finish planting and earth up those stools which have been left open during the preceding month. Continue to gather, hoe and weed the beds and the mounds. Keep a sharp look-out for the *Crioceris* and other insects. Destroy snails and slugs, both of which are particularly fond of the young heads just at the moment when they show their tips above the surface of the earth.

May.

Continue to gather, hoe and weed the beds and mounds. Wage incessant war against the Asparagus beetle and other enemies of the plant. In young plantations especially keep a sharp look-out for the cockchafer grub. Sticks are placed at the foot of the stems of the young plants to which they are tied with rush or bast; or else they are left unearthed, which is quicker and easier when Asparagus is grown on a large scale. If the season is dry, from 2 in. to 3 in. of soil is placed above the stools planted in the spring, so as to keep them fresh. When once they have begun to show any heads above the

ground, the stools may be covered to the depth of 6 in. without harming them.

June.

Discontinue gathering about the 10th of the month, or even earlier. We must cease gathering in those plantations which show signs of weakness, as well as those in which very early varieties have been planted, according to the season. A falling off in the thickness and length of the heads is a sure sign that the plantation wants repose. Continue to hoe. Let the young shoots be attached to training sticks, as directed in the preceding months. A sharp eye must be kept on the enemies of the Asparagus grower, the mole, the Asparagus beetle, and the cockchafer grub.

July.

This is the period at which the Asparagus beetle lays its second batch of eggs. This insect must therefore be well looked after, whether in the beetle or larvæ stage, or in

the attacks of their usual enemies. At the beginning of the month, however, a sharp look-out should be kept for any straggling beetles or white worms.

October.

In light and dry situations we may begin planting, but only in warm localities. In the north and centre of France, and *à fortiori* throughout the whole of England, it is better to wait for the spring. We should also towards the close of the month cut down the old heads and begin to unearthen, dressing heavily with well-rotted stable manure, artificial manure, oil cake, wood ashes, compost, &c. Damp soils are drained if they are intended for spring planting. Mixed mould, manures, and composts should be prepared for use in the coming spring, and a good supply of young plants should be secured beforehand.

November.

We now begin to force Asparagus in the open ground and in

Fig. 2.—Tying Machine.

the egg. War must also still be waged on the white worm. Hoe and weed where necessary. Young plantations in gardens in very light and dry soil must be watered, if the weather is very dry and hot, at least every fortnight, if possible. Young shoots should be tied to training sticks.

August.

Insects and other pests must be hunted down. The trenches and mounds must be hoed and weeded if necessary, and the taller shoots of the plants supported by sticks, so that the wind may not break them down. This is only necessary in situations which are exposed to high winds; in sheltered positions it is unnecessary.

September.

The work to be done during this month is very small. When Asparagus is planted in vineyards the work is limited to tying the long overgrown shoots to training sticks to keep the wind from blowing them down, or to prevent them from keeping the sun and air from the Grapes, and so preventing them from ripening. Weeding and hoeing operations are carried on if necessary weather permitting. At this period of the year the young plantations are usually free from

heat. The stems of the plants above ground are cut down to the height of 12 in., and then tied up in bundles for burning. The mounds are dug up and lowered, so that manure may be brought within reach of the roots. We continue planting during the first fifteen days of this month in dry lands. In the south of France we may plant during the whole of the winter. Unearthing is also continued, as well as manuring. The ground may also be prepared for the spring plantations. Borders and mounds and trenches are prepared for forcing.

December.

The work indicated in the month of November is continued, and unearthing and manuring are discontinued. Composts and manures are prepared for spring plantations and good plants are secured, if that has not been done already. Fresh manure should be added to those beds in the open ground where forced Asparagus is being grown, if the weather is excessively cold. Hotbeds are examined and, where necessary, fresh ones are made.

M. PARENT'S BUNDLING MACHINE.

The operation of packing the gathered heads into bundles has already been described as it is performed in the ordinary

bundling machine; but M. Parent has invented a bundling table which is in every way superior. It consists of a table provided with rising edges like a gardener's potting table. In the middle of it, as shown in the figure, a hollow has been cut to allow the packer to reach over his work. The gathered Asparagus is arranged on the table. In front of the workman is a semi-circular upright piece, as in the ordinary packing table. This slide is movable backwards and forwards, according to the length of the heads. At the further end of the table there is an upright frame, firmly fixed to it. In this frame is a slide with a backwards and forwards motion, and provided with a series of circular holes of different diameters, intended to receive the tips of the heads of the Asparagus and regulate the size of the bundles. These holes are cut into the slide but not through it, and have a depth of 1 in. or $1\frac{1}{2}$ in. In the upper part of the circumference a hole is cut so as to allow the last heads of the Asparagus to enter without any damage. If we want large bundles

Pinching off the Tips of the Shoots of Asparagus.—This operation is intended to do away with the necessity for supporting the young Asparagus shoots with the training sticks used to prevent them from being broken or blown down by the wind, and, according to M. Parent, to give greater strength to the stool. It is performed three weeks after gathering, the tips of the shoots being cut off by the aid of the *sécateur*. This cutting should be made between the twentieth and twenty-fifth branch in the case of female stools, and between the twenty-fifth and thirtieth branch for male stools, which are generally much the stronger of the two.

An attentive perusal of previous notes on the use of the plough will show the Asparagus grower that by following M. Parent's directions implicitly, he will save time in hoeing and digging, in planting, in earthing up, which can be done at the rate of $1\frac{1}{2}$ acre a day, in unearthing, which is performed with equal rapidity, in gathering, in packing, and in doing away with training sticks. The intervals and part of the

Fig. 3.—Asparagus Plough.

of Asparagus, we slide the frame backwards or forwards until the hole required is exactly opposite the semi-circular upright piece. The bar of the circular mould is marked with a line, a corresponding line being made in the upright fixed piece, so that the particular mould desired may be quickly brought into the proper position. The tying machine is also an ingenious contrivance, and is shown separately in figure 2. It consists of two handles, provided with rackwork at the base, and connected together by a leather strap. This table is so simple that it may be worked by a woman or child. The woman or child seizes the heads of Asparagus and arranges them in such a manner that the largest are outside, and lays them on the semi-circular upright piece with their heads in the mould. The mould being full, the strap attached to the left-hand handle is passed round the bundle and attached to the right-hand handle. By pressing lightly on the strap by means of the handles, the bundle is held tightly, the handles being kept in their places by the rackwork. A couple of strings are then passed round the bundle and tied firmly, the strap is released, and the bundle is fit for market.

pathways being under cultivation, the crops grown on them almost pay the rent of the land. The art of growing Asparagus still requires to be greatly improved, but it has made great progress during the last few years. By the plough system the Asparagus produced is not so fine as that grown otherwise, but it nevertheless yields excellent results and leaves a good profit to the producer. GODEFROY-LEBEUF.

THE LATE INTERNATIONAL POTATO SHOW.

FROM the following list of Potatoes exhibited at the Crystal Palace on September 17 and 18, it will be seen that no fewer than 2101 dishes were staged as compared with 1539 dishes last year, and 1744 in 1876. Of this total there were 1541 dishes of English and 560 of American varieties as compared with 1076 dishes of English and 668 dishes of American sorts in 1876, and 1039 dishes of English and 500 dishes of American varieties in 1878. These figures are interesting, as they demonstrate pretty clearly that the Potatoes of American origin are less popular for exhibition purposes than they were two or three years ago. The number of varieties exhibited were 152, as compared with 204 in 1876 and 168 in 1878, and of those 29 were of American origin, or 5 less than in 1876, and 8 less than last year.

In point of numbers International Kidney is at the head of the list, for no fewer than 108 dishes of it were staged, or an increase of 42 dishes on the number of this variety shown last year, and surpassing by four the number of dishes of Snowflake exhibited in 1876, when that variety was at the zenith of its popularity. Next on the list is Magnum Bonum with 96 dishes, or an advance of 34 upon the number staged last year, thus showing that this famous variety is held in high esteem by cultivators for exhibition, as well as those who grow Potatoes simply for home consumption. Snowflake, which stands third, was represented by 69 dishes or four less than last year. 54 dishes each were staged of Grampian and Porter's Excelsior as compared with 59 and 40 respectively last year, or a decrease in the one case of 5 dishes, and an increase of 14 in the other. Schoolmaster and Early Vermont were the only other varieties of which more than 50 dishes were staged, the actual numbers being 58 and 54 respectively, or a decrease of 12 dishes in the case of Schoolmaster, and an increase of 48 in the case of Early Vermont. The varieties forming the Lapstone race, which have hitherto figured prominently at the International Shows, were but sparingly represented, as a glance at the following list will show:—

Gardener's Magazine.

Potato Magnum Bonum.—This Potato with me has been very free from disease. From 28 lb. of seed I dug 8 pecks of good-sized Potatoes, amongst which I found only three diseased tubers. The haulm of this Potato was the last to become affected by the disease.—J. T., *Abwalton*.

DISEASE PROOF POTATOES,

This subject has recently been revived, and we are recommended to grow the variety called Magnum Bonum, which is declared to be disease proof. A writer in the *Standard* says that "our only remedy against disease is to return to natural propagation by crossing the best and strongest growing varieties." The same authority also adds that this system has already brought us one disease resisting Potato, and Mr. Shirley Hibberd writes to the same paper to explain that this Potato is Magnum Bonum. I do not know the history of that variety, but there can be no doubt, I think, that up to the present time it has escaped disease; that, however, is no proof that it is disease resisting. Its immunity from disease is due, I imagine, to its lateness, in which respect it may be compared to the Red-skinned Flourball, which is also disease resisting in the same way, but it is not such a good Potato as Magnum Bonum. I think it is generally admitted by both practical men and theorists that all kinds of Potato escape the disease till they approach the ripening period. As soon as they have done growing and begin to ripen then disease makes its appearance. This is exemplified every year in every plot of Potatoes where two or three varieties are grown, and it is also clearly exemplified in the same sorts in different localities. When they are late the disease is late in attacking them, and *vice versa*. For example, in our very late locality the Dalmahoy escaped disease this season up to the middle of the preceding month (Sept.), while in earlier places it has been completely destroyed sometime ago, and since the date just quoted it has gone quite bad with us also. I have carefully noticed the progress of the disease among our Potatoes here since it began, and I find it just to follow the varieties according to their earliness. It began with Mona's Pride, and took the following varieties in rapid succession and in the order named, viz:—Common Ashleaf, Rivers' Royal Ashleaf, Porter's Excelsior, Schoolmaster, Dalmahoy, the Grampian, and York Regent. The two last are the least affected yet, and Champion and Magnum Bonum are still quite free from disease, but far from ripe, the leaves and stems being still as green as a Leek. Magnum Bonum has just reached the turning stage when the skin begins to harden. Part of the crop we shall leave in the ground, and if October is mild, and it passes through that month without becoming affected, it will deserve the name of "disease proof," so far as this district is concerned, but I doubt it will go the way of the others when the critical period of growth has fairly turned. The variety which has produced the greatest proportion of sound tubers after lying in the ground for awhile after the haulm was ripe is Schoolmaster. The best croppers this season with us are York Regent and Magnum Bonum, but the last would require twice as much room as the first to do it justice. Champion is quite a disappointment as regards crop.

J. S. W.

DEPTH AND FIRMNESS IN SOIL ESSENTIAL.

The adaptability of the earth's surface for the production of the many forms of vegetable life must vary according to the depth and character of its permeable crust. Nature, in her cropping arrangements, notes this fact, and always plants the crop that is most suitable for the time being; but all things are progressive, and the first crop is only a preparation for the next; for as the character of the soil changes, so also do the plants it bears. Look at the crumbling ruin! first comes the grey lichen, and spreads itself over the face of the stones, gradually eating into their surface; then, as damp and frost, and the other forces Nature brings to bear upon all things in order to provide food for the myriads of mouths waiting to spring into active life, have performed their mission, other plants of larger development establish themselves, and the work of destruction and decay goes rapidly on. In the case of the drained swamp or marsh, the forces of Nature, aided by man, are working to the same effect, but in an opposite direction. In this case the strong-rooted semi-aquatic plants first appear, perform their work of assisting in the draining and aeration of the land, then disappear, and are succeeded by others of fibrous root growth, and finer but more nourishing herbage. So it is everywhere; when Nature is left to herself, the fittest only survive. In our cultural operations there is also a certain fitness of things that should never be ignored or lost sight of. We should imitate nature so far as to select the right plant for the position, or else fit the position for the plant; and both of these questions are worthy of much careful study. Some years ago, in carrying out some alterations here, I had an opportunity of increasing the depth of all our beds in the flower-garden to something like 3 ft. of good soil. The work was heavy, but I am sure the expense was a good investment, as a much better result, with less labour, has been obtained since; and what is perhaps of greater importance, we are pretty well independent of the seasons. For this year, which is an admittedly unsatisfactory one, our beds have never been better filled; the greater depth of soil has supplied perfect drainage, and

consequently warmth; and, although the growth was slow, yet it was continuous and of a floriferous character. The improvement wrought by deepening the soil is great, and there are collateral advantages connected with it which all who have had much to do with the cultivation of land will readily admit. Shallow soils must be fed continually, or they lose their power of production; for we have otherwise no hold upon their fertility. The manurial matters are either quickly washed out, or the vegetable matter they contain is dried like tinder by the fierce heat of the sun. When the soil is deep it has greater power of retaining whatever is given to it. As both temperature and moisture are more equable, being less influenced by external circumstances, and if only a loose friable surface is maintained, other cultivating operations are never so urgent, and may be—in fact, are best done in winter, which gives plenty of time for consolidation; and this latter condition (firmness) is quite as essential in most soils as depth; for unless the land is reasonably firm, the plant or tree cannot get a good grip of it, so as to produce short-jointed growth. Most plants when growing in a bed of loose soil will make long soft fibreless roots, and the top growths always, in some degree, corresponds with the progress of the roots. And where the latter rushes away in a bed of soft earth, the top is usually as bare of branches at the base as the main roots are of fibres. This is a matter that should be allowed to have some influence upon the construction of Vine and other fruit tree borders. Where these have to be made, the most perfect plan would be to adopt a piecemeal system. Plants are like most of the lower animals, they have no power of self-control when exposed to the temptation of high living; and under our artificial system of cultivation of the choicer kinds of fruits, success will in a great measure depend upon the control the cultivator keeps over their food supply.

E. HOBDAV.

THE FRUIT GARDEN.

ROOT PRUNING.

At this season of the year one would imagine, judging from the many directions given for root pruning, that it was an operation of daily occurrence, whereas its beneficial effects are by many not only doubted, but it is thought that positive injury is in many cases inflicted on healthy trees through its being injudiciously performed. A fruit tree may be observed to be making extra vigorous growth, and forthwith the inexperienced cultivator having read of the wonderful results of root pruning, proceeds to cut off a quantity of its roots, whether that is necessary or not. Root pruning is certainly useful in some cases, but from my own experience in various soils and localities, I am convinced that in nine cases out of ten, if a tree cannot be got into a fruitful condition without perpetually lifting, replanting, and root pruning, the sooner it is uprooted and thrown away the better. I well remember the time when it was considered unsafe to manure fruit trees, but now they are proved to repay generous treatment equally well as any other kind of tree. In this neighbourhood fruit culture for market is one of our largest industries, and a large amount of capital is invested in it by men who have followed it as a profession from boyhood, and who lose no opportunity of putting anything into practice likely to make their trees more prolific and remunerative. But root pruning is not practised, and I may say is unknown, worthless or worn-out trees that are not vigorous enough to graft being grubbed up and burned. The secret of the Kentish fruit grower's success, in addition to a naturally strong soil, lies in enriching it well before planting; indeed, the majority of young orchards hereabouts succeed old Hop plantations that have been highly cultivated and manured for years, and the growth which the young trees make under such conditions would alarm the advocates of root pruning. By carefully selecting sorts, however, that do bear crops, the owners, as a rule, get well rewarded, and if a crop happens to fail it is not superabundant vigour that is blamed. The pruning is varied according to the habit of each variety, and as regards the Apple, truly the king of fruits about here, very little pruning is done in reference to it after the tree commences to bear. The ordinary mode is not to prune at all the first year after planting; but the following year, and for four or five years afterwards, the leading shoots are thinned out and shortened until a well-balanced head is formed. After that the trees are looked over every alternate year with the view of keeping their centres clear of useless spray, but the outer portions are left quite thick, forming regular umbrella-shaped heads, varied only by the natural growth of each particular variety, and as the trees are generally planted in rows of distinct sorts, any one may distinguish the kinds that are most esteemed by their numbers and habit of growth alone.

If a tree of any kind does not prove to be fruitful the remedy consists in sawing off the whole of the outer branches when they are

about the size of a broom handle and putting two grafts on each. Thus a good-sized tree may have fifty or more grafts upon it, and owing to comparatively young wood being used they seldom fail; on the contrary, they grow vigorously and quickly cover the cut portion with new wood, leaving no decaying dead wood, as is the case when the trees are headed down low and large limbs grafted. It is astonishing how quickly fine, free-bearing trees are obtained in this way, and common strong-growing kinds make the best of stocks on which to work better kinds. Thus double grafting almost invariably produces fruitful trees, and the more vigorous they are the finer is the fruit.

I may mention that many of the largest growers have a special plot or trial ground for proving new or but little-known sorts, which receive liberal root treatment. I lately saw a quantity of young pyramids which, the first year after bearing, were carrying excellent crops of finely-coloured fruit that looked as if it had passed through a favourable summer, so bright and clear was it. The soil in which they grew was well cultivated and manured and only lightly cropped between the trees, while two and three-year-old trees were generally carrying good crops of such fruit as the starving and root-cutting process could never have produced. My impression is that fruit trees of all kinds are more frequently induced to become barren and to make gross, watery shoots instead of fruitful spurs by starving than by over feeding, as if they cannot find soluble food near the surface they are sure to root down into the cold subsoil. I have tried mulching the roots of Peach and other tender wall trees that had for years produced gross, immature wood and no fruit, and without any interference with the roots beyond forking up the surface and adding a little fresh loam in autumn, and a good mulching of partly decayed manure in the early summer months; they have soon filled the walls with good bearing wood. I am aware that soils and seasons vary greatly, but I never yet could see the benefit of taking any kind of tree up to examine its roots, as the character of the top-growth will, as a rule, determine that matter. If every means is taken to get healthy, fruitful wood, roots of a similar character are sure to follow, and if well treated they will take care of themselves. The orchards here are cultivated and enriched the first few years, and when laid down with Grass are grazed with sheep. It has been amply proved that if the Grass is cut and carried away the trees soon deteriorate, but if grazed with oil-cake fed sheep they improve and bear heavy crops. If one looks at the weight of fruit which in favourable seasons a healthy tree will produce, it follows that the soil must soon become exhausted if means are not taken to replenish it through the application of rich food applied on the surface. I would strongly recommend any one wishing for fruit in abundance to let the roots of healthy trees alone, and try mulching and top-dressing, and only practice on old or useless trees by wholly uprooting them to make room for young ones.

JAMES GROOM.

Linton.

NOTES ON FIGS.

Negro Largo.—Some time ago I was assured by Messrs. Veitch & Son, of Chelsea, that the Negro Largo Fig was likely to prove an excellent forcer, like the Brown Turkey; and, after a short trial, I think I can indorse that opinion. There are great differences in Figs in this respect, and it is important to know what sorts force freely in the case of plants that have to be forced for two or three crops in the year. Some kinds are not worth the place they occupy for this purpose. I received two small plants of the Negro Largo last year early, and this season I put both plants into 20-in. pots at once, with the object of making big plants of them quickly, and not thinking of a crop. They, however, showed a quantity of fruit on the last year's wood, which did not all drop, though the plants had been shaken out just before being started, and later on produced a better second crop, every fruit of which has come to maturity and proved excellent. I consider this good promise in a plant that has plenty of root room and is being encouraged to grow strongly at the same time, for nothing is more inimical to fruitfulness in a Fig than free root action. The fruit is good-sized and of a purplish black colour.

Raby Castle.—This is another extraordinarily prolific variety, and produces two or three crops in close succession; fruit moderately large, not very high flavoured, but very sweet and agreeable. When planted out in the border, the fruit is much larger, and produced more freely than with most kinds under similar treatment. I believe there is a fine old plant of this fig at Raby Castle, from which the name is derived. In the "Gardeners' Assistant," new edition, this Fig is described as synonymous with White Marseilles; but those who have seen the two grown together would never confound them. The Raby Castle is larger than the Marseilles. In some cases we have seen it as large as the largest Brown Turkey; but it bears such

a quantity of fruit that, unless thinned, they do not attain to their true size.

Peyusota and Grosse Bourgassotte we have also tried during past years, and find both to produce fruit of excellent quality; but they do not suit our purpose so well as the old Brown Turkey or the Negro Largo. J. S. W.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Hedge Nuts.—When recently in Kent, I examined a large number of small Nuts gathered from the hedgerows, and found that three-fourths of them were devoid of kernels; indeed, the inside was quite black, although the shell was perfect. I fear those who have been reporting the abundance of small Nuts will find that the crop is after all but a very poor one. That the trees should in this way produce shells or the woody portion of the fruit without any corresponding edible part is singular, and probably entirely confined to Nuts. Plums, Peaches, &c., never produce the luscious fleshy portions of their fruits, except the kernel is entire, and any deficiency there renders dropping of the fruit inevitable. It is almost strange that the same result does not follow to hard-shelled fruits. The experience of the present year will make us chary how in future we report early in the season upon the Nut crop.—A. D.

Grapes Shankng.—In one of our Vineries here we have about half-a-dozen bunches badly shanked, and the shoot on which each of them is growing happens to have no leaves or wood beyond the bunch; other bunches with plenty of leaves beyond them show no signs of shanking, and judging from this, one would be inclined to think that close pinching is one of the causes of shanking.—CAMBRIAN.

Autumn Treatment of Raspberries.—Those who wish to give their Raspberry canes a fair chance of producing a good crop of fruit next year should lose no time now in cutting away all the old canes which have been bearing this season, and in tying the young ones into the places in which they are to fruit next year. At the same time all small growths that are not wanted should be cut away so as to let as much air in as possible to ripen the fruiting wood. We adopt the above plan annually and find it to answer admirably. We always tie our Raspberry canes with small Willows, which we find both cheaper and more durable than twine or matting.—CAMBRIAN.

A Word about Apricots—Since 1854 there has been no more trying season for Apricot trees than this, the trees dying while in flower and in fruit. It is peculiar to find Apricots grown so generally as they are in Cleveland; about Great Ayton, and other villages they may be seen on almost every house, and without much regard to aspect, but in most cases they have suffered much; indeed, in many cases quite killed. In front of the Workhouse at Stokesley the Apricots used to be quite a sight, their fruit bringing a return of from £10 to £12 per year; the trees now, however, seem to be quite wrecked. This week I have examined about thirty of them, chiefly planted against cottages, and I have found them to be all less or more in a decaying condition, and in most cases there is the appearance of bad grafting. In trees where the union of stock and graft appears sound they are clearly in better health. It is to be regretted that so little attention is paid by cottagers to planting healthy young trees. It is assumed by every one about here that Moorpark is the best variety, and mere fragments of trees of it are planted which remain for years in an unfruitful state. The Royal Apricot is, however, the most fruitful and most healthy in Cleveland; this season on young trees of the Early Oullins the fruit ripened well, but it is not much planted. From a tree of the Royal variety on a cottage in Stokesley, planted in a paved yard, I have seen gathered this season over 240 fair-sized Apricots, the market value of which was thirty shillings. The tree in question was planted five years ago by Mr. Barker for one of his workmen, and for three seasons it has produced fair crops. It is worthy of note that rider-trained trees are decidedly the best for yards or road-sides in villages.—CHAS. McDONALD, *Stokesley*.

The Hail-storm Relief Fund, 1879.—The large number of applications which have been sent in to the committee for relief from the fund—sixty-eight in number—is indicative of the great amount of suffering caused by the hail-storm of August 3. Many of them are piteous appeals for assistance, if only small in amount, to meet pressing necessities, and it is an indisputable fact that a large quantity of broken glass remains to be repaired from want of means to replace it. The sixty-eight applications for relief represent an aggregate amount of stated damages, amounting to £3,600. In addition there is, on the part of some members of the committee, knowledge of sufferers who are too modest to advance requests for assistance, but whose cases will not be overlooked. £800 (the pre-

sent amount of the fund, and from which the working expenses have to be deducted) is but a small sum comparatively with which to relieve so much pressing necessity, and the committee are now making a further appeal for subscriptions. The sixty-eight applicants for relief reside in so large a district that it has been found necessary to sub-divide it into four divisions, and an investigation sub-committee has been appointed for each of them. Such sub-committees are now at work examining statements, overlooking breakages and repairs, and collecting reliable information so that each applicant may have his case fairly set forth. The work is heavy, but it is being readily and gladly done by properly qualified practical business men. It is important that the fund should be shortly closed so that, concurrently with the consideration of the reports of the investigation sub-committees, the existing committee can make their awards and administer relief. Will all who are willing to help be good enough to contribute the same without delay; The sooner the work can be brought to a close the more welcome will be the relief to be administered to those who are sorely in need of it.—RICHARD DEAN, *Ranclagh Road, Ealing*, EDWARD KING, 14, *King St., Richmond*, Co. Hon. Secs.

GARDENING IN SOUTH AFRICA.

THE following interesting remarks on this subject have been forwarded to us by Mr. James O'Brien, of the Pine-apple Nursery, Maida Vale, for publication in *THE GARDEN*:—

“Kraggakamma, March, 1879.—I think you know that our ship on her way from London to Algoa Bay called at Cape Town, where we stayed three days; during that time I went on shore and had a look at the town. From its situation, facing the midday sun, it is exposed to great heat, and is immediately backed up by naked mountains; quite close to it is the much-talked-of Table Mountain. Over the top of the mountain hung a beautiful white mist or cloud, but nevertheless I had an irresistible longing to go up to see growing wild the glorious *Disa grandiflora*, about which I had heard so much at home. Therefore, on the day of my arrival in Table Bay I made arrangements with a native guide to ascend the mountain the next day, and accordingly on the Wednesday morning (Feb. 19) we set off. When about half way up we halted, and after resting about half an hour we made a fresh start, and after about three hours' hard climbing we reached the summit. Although the mountain is only about 3600 ft. high, I found that I had much underrated the task which I had set myself; but I was intensely gratified on my way to find growing wild several species of plants which I had had under cultivation at home. If I may venture to name *Heaths*, *Erica gracilis* was growing by the side of the path for a mile or two, and also a scarlet variety. Of *Pelargoniums* I only saw a very small zonal—as small as *Harry Hieover*, and with flowers of the quercifolium type. *Crassula coccinea* was very bright and striking, and I also noticed a dwarf *Agapanthus* with very short foliage and flower stems about 15 in. high, very much resembling a tall-growing *Scilla*, such as *S. campanulata*. There were not, however, many plants in flower, as February is the end of the summer here. I found several *Sedums*, a very dwarf *Crassula*, *Santolina erecta*, *Asperula montana*, also a plant exactly resembling *Leucophyton Browni*, great quantities of *Pachyphyton roseum*, several *Everlastings* (*Helichrysums*, *Xeranthemums*, and *Aphelexises*), a few *Ferns*, *Blechnum Spicant* (true), and *Asplenium Belangeri*; but these were not what I had in view, so I pressed on and found myself on the so-called Table. Here a scene of indescribable grandeur presented itself. This was the first time I ventured to look around for a few minutes; then, continuing on our way, we came to what I will call a very rough meadow, the whole surface of which was covered with coarse Grass and other plants just gone out of flower—not a small space of ground, but several acres in extent, with rock rising up all round it; and wondrous were the grotesque-looking forms of the rocks. Travelling across this meadow for half a mile or so, we came to a small stream 8 in. or 10 in. deep, seemingly formed out of the solid rock. Here you may imagine my delight, when I had wiped the mist away from my eyes and beheld the wonderful *Disa grandiflora* in full flower. The *Disas* grow just in such places as one would expect to find the *Myosotis sylvatica* or *palustris* wild at home, that is, just on the edge of the water, which at times overflows them; and the soil consists of decomposed rock, in which the bulbs are fixed so tightly that to get any quantity of them one has to use considerable force to get them up. Where they grow, too, the air is very cold, so much so that I was glad to put my coat on, and there were several heavy clouds overhead, which kept the atmosphere quite moist. I followed this stream about two miles, and found flowers here and there the whole distance, and when we had gathered as many as we could fairly carry in our hands, I took a few tubers. We then retraced our footsteps, gathering as we went along some other plants which quite filled our

baskets. Passing down the west side of the mountain, we got the full benefit of the afternoon south-west African sun, and by the time I reached Cape Town I had had quite enough of Table Mountain for one day, the distance travelled being about 20 miles. I was very fortunate to ascend the mountain when the Disa was in flower, but, at the same time, I must say that there are many other plants well worth going a long way to see that blossom early in summer in this latitude, *i.e.*, judging by the numbers of dead stems to be seen among the rough Grass. I must not forget to mention that on the slopes of another mountain adjacent to Table Mountain, called the Lion's Peak, is growing the Witteboom, or Silver Trec, conspicuous for the beautiful silky whiteness of its leaves. My guide went over and brought me a branch, and told me that it was much used for church decoration.

Next day (Feb. 29) I visited the Museum and Botanic Gardens, Cape Town, and here I was introduced to Mr. Johnson, the manager of the glass department in the gardens. I was first conducted to the conservatory, which is filled with a general collection of stove plants, all in robust health and beauty, proving that a master hand was at work amongst them. In the centre transept is a large bed a trifle higher than the floor. In this some plants are planted out and some in large pots. Palms in particular are very good. But the crowning plant in this part of the house was a handsome young *Musa Ensete*, which Mr. Johnson told me he planted ten months ago, when it had only two leaves, while at the present time it has fourteen, each measuring from 18 ft. to 20 ft. in length and 2 ft. 6 in. in width. On the roof were several climbers in fine condition with the exception of one, which covered part of one side, *viz.*, *Clerodendron splendens*. This was past its best but was flowering most profusely. There were also *Telfairia pedata*, *Allamanda Hendersoni*, a fine *Antigonon leptopus*, and the old-fashioned yet handsome *Combretum purpureum*. Turning from the centre transept into the north-west wing there is a general collection of young stove or warm house plants. The south-east end or wing of this house is filled with an excellent collection of specimen plants, amongst which variegated plants were unusually bright, a circumstance which Mr. Johnson attributed to the extra light enjoyed here. I also noticed some good Ferns and a fine collection of established Orchids; some of them had finished their growth, and others were making such stout well-formed growths as I never saw before. And here in my ignorance I looked round for the heating apparatus, but found none; none of the houses here are heated, but a certain share of sun heat is husbanded, so to speak, and other matters of detail are skilfully managed by shutting out the hot, drying winds, and cold winds too, the winds here being very strong and cold at times, especially in the evening in autumn. In the show house, amongst plants in flower, was *Hydrangea Dr. Hogg*, a kind of which Mr. Johnson speaks very highly. Leaving the houses I had a look round outside; there I saw good collections of *Azaleas*, *Camellias*, *Fuchsias*, and *Pelargoniums*, and in frames *Gloxinias*, *Gesneras*, *Tydeas*, *Bouvardias*, *Poinsettias*, and *Hydrangeas*, which, I was informed, were to be grown largely for decorative purposes.

Port Elizabeth is 500 miles from Cape Town, and when we left for that port I heard it remarked by more than one that steady persevering working gardeners were much wanted about Cape Town, vegetable growers for market in particular, a fact which may be welcome to some of the stout-hearted young gardeners who are waiting in nurseries for places. I am sorry I did not come here myself twenty years ago. Crops come up here much quicker than at home; it is possible, for instance, to get three crops of Potatoes in twelve months off the same piece of land. Radishes sown on March 4 were ready to draw on the 26th out quite in the open garden; Potatoes planted in January will be lifted to-morrow (March 31), and we are now busy planting Potatoes which will be ready in July, the depth of winter here, but which is never so sharp as to destroy a *Heliotrope*.

Let me now enumerate a few plants that I have found growing here, some wild, some in gardens. First on the list is *Plumbago capensis* in endless profusion, all through the bush everywhere; even garden fences are formed of it. Next comes a green *Tradescantia* with large blue flowers, quite a pest all over my garden. *Callas* abound in the ditches, and here and there *Mesembryanthemums* are plentiful; also *Lobelia speciosa*, and another kind which I never noticed at home, with beautiful dark blue flowers borne on rather long stalks. *Lithospermum prostratum* too grows here, and its growth is quite as hard as well-ripened *Rosemary* branches, but it does not grow more than 3 in. or 4 in. high. I also found a dwarf *Tritoma* in flower, and we have the *Boussingaultia baselloides*, *Alonsoa incisifolia*, *Gazania*, and some thousands of small bushes, about 18 in. high, very much resembling *Leucophyton Browni*. We have three plantations of *Bananas*, and three varieties which, I believe, have been planted where they are. Of flowering plants that have been planted, first on the list stands *Bougainvilleas*, three varieties; next *Oleanders*, pink and white, in company with *Gardenia*, *Weigela rosea*, *Syringa*, *Sweet-scented Verbena*, and *Poinsettia*.

Stove plants planted out here without protection thrive wonderfully well. I am going to try *Hoya* and *Stephanotis out-of-doors*; also *Dipladenia*. *Aloes* are not so plentiful here as at Cape Town. I have a very fine old plant of the *Prickly Pear* in my garden. Of this I see the farmers make hedges. I may mention that I saw a very fine old plant of *Opuntia eocinillifera* in the Botanic Gardens of Cape Town, with a swarm of cochineal insects feeding upon it. I have no Palms, neither have I seen one growing wild here. I have in my flower garden three splendid plants of *Enccephalartos* planted out on the lawn. The "Bast" hereabouts consists of low-growing, stunted, very hard-wooded deciduous scrub. There is very little timber here, but what there is very valuable. We have one variety in particular called *Yellow Wood*, which is very durable. I find this wood to possess great heating power, judging from the short time it takes to heat water to the boiling point.

As regards my home garden, I must admit that I am favourably situated in a vale with plenty of water; I have I ought to say, several natural springs, one of which in particular has never been known to fail; and what we grow is simply the same kind of produce that we grow at home, both as regards fruits, flowers, and vegetables; the only difference is that everything grows much better here than at home, and very much quicker, and we are not required to protect anything from frost. The Melon is grown here in open fields; sometimes a spadeful of manure is put in at the time when the seed is sown, which is in August. I have just now a fine lot of *Roses*, and our *Chrysanthemums* are coming into flower.

Kraggkamma, Port Elizabeth.

J. HALL.

ANSWERS TO CORRESPONDENTS.

Artificial Bog.—What is the best way to set to work to make an artificial bog in which to grow *Bamboo*, *Gunnera Osmunda*, &c. in the centre; and towards the margin *Sarracenia*, *Cypripedium*, *Pinguicula*, *Drosera*, &c.? I have a piece of ground about half an acre, with a few moderate sized Oak and Chestnut trees, and also a few evergreen shrubs thinly scattered over it. A ditch about 18 in. deep runs along one side; in this there is a very small but never failing stream of water. The ground is nearly level with a slight fall to the south, the soil a good but rather stiff loam.—E. G. L. [Most of the hardy sub-arctic plants will thrive if planted at the edge of a stream in peaty soil, and so arranged that their roots can penetrate a constantly sodden soil. To make a separate bog garden the best way will be to cut a ditch at any point of the existing ditch at a sharp angle with the direction of the current, so as to divert its course a little. The island space thus enclosed will make a capital artificial bog if the soil be taken out a little lower than the newly formed ditch, so as to allow a slight fall for the water to drain to the main ditch. At the bottom of this bed place a layer of rubble, such as clinkers, so that the water may drain through; upon the top of this lay the soil, which will be found to keep constantly moist, and bog plants will delight in it. About 1 ft. or 15 in. of soil will be enough for the large growing kinds, and a proportionately thinner layer for those of smaller growth.—G.]

The Silver Lime.—The enclosed leaf and flowers were plucked from a Lime tree in full flower on the 7th inst. The foliage differs entirely from that of the Lime trees in the neighbourhood (the common variety which flowers in July). The leaves and flowers, particularly the latter, are larger. The flowers are more scented, and different in colour from the usual ones. The leaves, moreover, are very light in colour on the underside, and smooth on the upper surface. Can you name the variety? The specimens enclosed come from the park near Ely Cathedral.—GILBERT R. REDGRAVE *Summerville, Muscull Hill.* [Your Lime is the beautiful *Tilia argentea*, a tree much too rare in this country. There is a good coloured plate of it in "Reichenbach's Flora Germanica," VI., t. 324. It is a native of S. E. Europe and Asia Minor.—H.]

French Marigolds.—J. C.—Both the yellow ground, maroon flaked blooms sent, and also the dark self-coloured ones are the best of their kinds which we have ever seen. They show in a striking manner the good results arising from careful selection.

Twinn Cucumbers.—F. G. C.—These are not uncommon, but it is seldom one sees so fine a specimen as that which you send.

Double-flowered Fuchsia.—G. Fry.—Your seedling named Miss Lizzie Vidler is a large and fine flower, very double and striking in colour, the sepals and tube being bright crimson, and the petals violet shaded purple.

Auricula.—Mr. Robert Trail's address used to be Aberleidy, N. B., but he has been dead about twelve years.—J. D.

Names of Plants.—E. D.—1, Probably a species of *Pleurothallis*, but too much damaged to name correctly; 2, *Epidendrum cochleatum*.—S. W. B.—1, *Coprosma Baueriana variegata*; 2, next week.—A. X. Z.—The *Procumbent Pearlwort* (*Sagina procumbens*), a common native weed. It is doubtful if any seedsman could supply seeds of it.—E. H. W. E.—(*Alceolaria chelidonioides*.—R.—The Marsh *Hypericum* (H. Eloles).—T. T. W.—*Euonymus europaeus*.—V.—*Berberidopsis corallina*.—M. B.—1, *Hypericum oblongifolium*; 2, *Aster Amellus*; 3, *Chironia decussata*.—Devon.—1, *Adiantum Capillus-veneris*; 2, *Asplenium Ruta-muraria*.

Questions.

Heating.—How many pipes should be used for a brick pit 6 ft. wide to give sufficient heat for the moderately early forcing of Cucumbers and Melons? I want to work half the length at a time. Also the best material with which to cover the bottom pipes? And would the top pipes be the better for being furnished with evaporating troughs? Also what distance should they be from the glass?—B.

Asparagus Dying from Wet.—I hear of great destruction of *Asparagus* in North Wales owing to the heavy rains that fell in the autumn of 1877. Have any of our correspondents noticed a similar loss in other parts of the country? Has Mr. Godfrey Lebouf heard of it in northern France or Belgium?—B. H.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NOTES OF THE WEEK.

Kiosque in the Regent's Park.—It is very doubtful if this is an improvement. It is certainly not so from a landscape gardener's point of view. Every brick raised on another in a public park is a nuisance in itself, and may also prevent improvements. It is a most doubtful innovation; no matter how well done, it tends to give a tea-garden aspect to a fine public garden. Granting that such things are really necessary, the proper place in which to erect them is the outskirts of the park, or even entirely outside it. Very near the structure recently put up there are two small gate lodges, with either or both of which it might have been connected. If this example is much followed in other parks we must bid farewell to their quiet beauty. Such tea-houses and the like might be necessary in the middle of Epping Forest, and would be very welcome in the desert, but they are not a necessity in parts of the parks only a few minutes' walk from houses and streets.

Pictures in Leaves.—On these fine October days one may look in vain in some of our large public gardens and parks for a good illustration of the great beauty of tree foliage in autumn, artistic attempts to show it being very rare. This is a pity, as there is no effect of the year more beautiful, even as often shown by a few native trees. The advantages the planter has in selecting trees from various countries, with the habit of dying off in rich or deep colour, are so great that he ought easily to charm us, especially in large public and other parks where there is plenty of room. But perhaps we are asking too much, especially in days when so much thought and labour are bestowed on the many edgings of the little yellow Feverfew, which produces such a ridiculous uniformity round the smaller plantations in many gardens, public and private, now. When Mr. Elliot found this little variety he probably never imagined how much thought and taste it would save.

Beloperone oblongata.—A flowering spray of this beautiful Acanthaceae shrub has been sent to us from Sir George Macleay's garden at Pendell Court, Bletchingly, where it has for some time past enlivened the stove by its long wreaths of pretty rosy-purple flowers. The following note respecting its merits from Mr. Green, the gardener at Pendell Court, accompanied the specimen: "Although this interesting plant is said to have been introduced from Brazil so long ago as the year 1832 it seems as yet but little known, and not so much I think as it really deserves. It is a very desirable plant and forms a compact bush about 2 ft. high. When planted in a rich border in a warm house it will flower freely for several weeks together; the flowers are of a rosy-purple colour. It also makes a neat pot plant when treated in a similar way to *Justicia speciosa*, so well known in gardens."

Philydrum glaberrimum.—This is a handsome plant now in flower in the Temperate House at Kew. The leaves are sword-shaped, nearly a yard long, leathery in texture, of erect habit, and arranged in a manner similar to that of an Iris. The flowers are pure white, small, and wax-like, but very numerous, placed on long, branching spikes, which considerably over-top the leaves. It is doubtfully considered a native of Polynesia. It derives its specific name from the shining surfaces of the leaves, whereas the only other species of the Order has the leaves covered in dense woolly hairs. It forms a handsome greenhouse plant, and one that deserves more extended knowledge. It is such fine plants as this, and there are many equally beautiful that flower occasionally at Kew, that need to be better known and cultivated, in order to infuse greater interest and tend to relieve the monotonous effect of the ordinary types of greenhouse decorative plants.

Australian Oranges.—A consignment of these has been received by Messrs. Howeroft & Watkins, Covent Garden, from Adelaide, which is probably the first importation of the kind in quantity that has reached this country. The experiment so far is most successful, as the fruits are in excellent condition. They consist principally of Madeira and Naples Oranges and a smaller quantity of Palermo Lemons. Various modes of packing have been resorted to for experiment; in some cases the fruits were packed in sawdust and paper; in others half paper and half sawdust, whilst the main bulk was packed in sawdust only; and these were in the best condition. On several of the fruits wrapped in paper were specks, caused probably by dampness in the paper. Forty-two days only

elapsed from the time when they were shipped until they reached Covent Garden Market. At this season, when Oranges are retailed at high prices, no doubt large shipments from Australia would prove remunerative, if similar success could be ensured as has attended this experiment.

Nepenthes villosa.—Some of the finest examples we have met with of this extremely rare and distinct pitcher plant are growing in baskets in the stoves in the York Nurseries. We counted as many as thirteen fully developed pitchers on some of the specimens, varying from 6 in. to 9 in. long, with a diameter of 2 in. to 4 in. They are pale green in colour, covered on the outside with soft reddish-brown hairs, which also cover the under surfaces of the leathery leaves. The two hairy-edged wings on the outside of the pitchers are narrow, but the unfolding ribbed margin round the aperture is unusually broad. The lid is oval in shape, and raised high above the aperture, and in mature pitchers they assume a deep crimson hue. It is also known under the names of *N. lanata* and *N. Veithei*.

Gardening in the Parks.—This has been a wretched season for "sub-tropical plants" in the parks. Perhaps a few more such seasons may teach the lesson that, as regards our public parks, it were better to attend more to hardy trees, hardy flowering shrubs, hardy florists' flowers, and the numerous herbaceous plants now in cultivation than to spend so much money in the erection of villages of costly glasshouses which are devoted to the culture of the tender exotics. These, after all the trouble and expense they occasion, often present a miserable aspect, even for the few months they are visible.

Samolus littoralis.—Conspicuous among the bog plants that are placed along the edge of the hardy aquatic tank at Kew is this pretty plant, which is now very attractive. It has slender, trailing branches 1 ft. or more in length, furnished with small narrow leaves, from the axils of which are produced the rosy-pink blossoms, which are round and about $\frac{1}{2}$ in. across. Flowering at this season, and bearing a succession of flowers for a considerable period, renders it a very desirable plant for growing with other moisture-loving plants by the edge of a pond or ditch, or in pots partly submerged. It is a member of the Primrose family, and is found abundantly in marshy places near the sea in Australia and adjoining islands. It may be easily propagated by seeds or by layers, as the tips of the branches root freely when in contact with soil.

Primula capitata.—Of this charming Primrose there appears to be several forms in cultivation, differing from each both by the size of flower heads and the intensity of the colour of the flowers. One of the finest varieties we have seen is now in flower on the rockery at the York Nurseries. The pips also are larger than the ordinary varieties, and of the deepest purple colour, which beautifully contrasts with the white mealy substance in which the flowers are invested, and the rich green of the foliage. This is certainly one of the finest Primroses we have from the Himalayas, and one that should be included in every collection.

The Showy Meadow Saffron (*Colchicum speciosum*).—We have received from Mr. Stevens, examples of an unusually fine variety of this beautiful bulbous plant (Plate lxxi, Vol. XIV, of THE GARDEN), which has for some time presented a gay appearance in his garden at Byfleet. The divisions of the flowers are considerably longer and more pointed than in the type, and moreover it possesses a brighter tinge of colour. It is to be regretted that these fine autumn-blooming bulbs are not more frequently planted than they are, for they are very welcome at this season when the majority of other hardy flowers are past their best.

A White Watsonia (*W. alba*).—A border skirting a wall near the herbaceous ground at Kew is devoted to a collection of tender bulbous plants, principally from the Cape. Amongst them is this beautiful kind which, from its large and pure white blossoms, is one of the most desirable we have seen in flower amongst them. From the old and better known *W. Meriana* it differs by the pure white colour of the flowers, which are also much broader in proportion to the length, and also by the leaves not having such shining surfaces. It is the same as we saw at Mr. Ware's nursery last year, but, owing to the unfavourable season, the plants there have not flowered this year.

Yellow Bands Round Beds and Shrubberies.—It is an odd thing that people do not see how much harm they do their gardens by putting those yellow bands of Feverfew round shrubberies, &c. Everywhere throughout the land you see a miserable yellow line of this poor little plant, well enough in itself, but alas! prostituted to a poor end; for any beauty or variety that might be in your border is of course neutralised by these bands. It is, if anything, more sad than the poor bedding *Perilla*, another plant spoiled by being over-planted.

The Colchicum Family.—The last number of the "Journal of the Linnæan Society" is devoted to a synopsis of this family and some tribes of the Lily family, by Mr. J. G. Baker, of the Kew Herbarium. The value of this and similar treatises issued previously by the same author to plant cultivators can scarcely be over-estimated, as it gives an account of all the known species and principal varieties, together with their synonyms, a matter especially useful, as there are few genera of cultivated plants in which so much confusion exists in regard to nomenclature as the Colchicum.

Early Flowering Chrysanthemums in Finsbury Park.—A good effect is made in Finsbury Park by plants of early flowering red, white, and yellow Chrysanthemums being dotted about in little mounds on the turf. They occupy a position at the foot of an undulated bank—just such a place, in fact, as would be chosen for the more tender Palms and similar plants used during summer in the sub-tropical garden. This arrangement suggests what might be done in such places by using in a similar manner some of the best hardy spring and autumn flowering plants. As in the case of the Chrysanthemums in question they might be grown in pots and plunged in the turf when commencing to bloom. Some of the best of the Michaelmas Daisies, for example, would make excellent subjects for this purpose; as would also the Japanese Anemones, and some of the hardiest tuberous-rooted Begonias, which naturally flower best at this season of the year.—S.

The Dwarf Chionodoxa (C. nana).—In the present number of the "Botanical Magazine" this pretty species is well figured. Though the name may be new to the majority of cultivators, the plant is by no means a novelty; indeed, it is one of the oldest introduced kinds, and has been long known under the name of *Puschkinia scilloides*, which, however, is incorrect. The plant to which the latter name was originally applied is now generally known as *P. libanetica*, or *P. sicula*. It is stated by Mr. Baker to be a native of the mountains of Crete, where it is found at an altitude of from 5900 ft. to 6000 ft. above sea-level. It is a rare kind in cultivation, and well worthy of culture. It produces its pretty lilac-blue flowers in May, but they are much inferior in point of size and brilliancy of colour to the beautiful *C. Lucilia*, which was introduced by Mr. Maw from Smyrna about two years ago.

Bouvardia Humboldtii corymbiflora.—This is one of the best white flowered plants at present to be found in the London flower markets. It is there seen in the form of neat bushy plants in 6-in. pots, thickly furnished down to their bases with deep green healthy foliage, each shoot being surmounted by a beautiful head of large snowy-white, sweet-scented blossoms. Such results may be brought about by plunging the plants out-of-doors all the summer, or by turning out the plants into beds of well-prepared soil, mulching the surface with well-rotted manure, and affording the plants liberal supplies of water both in a pure state and in the form of liquid manure during hot weather. Early in September the plants are removed to a cool airy frame or house, where those which have been kept in pots speedily open their blossoms; those which were planted out, having been duly potted and kept close for a few days until re-established, flowering a little later, and forming a succession. For associating with Chrysanthemums, Salvias, and similar subjects, few plants are equal to this *Bouvardia*, and few are more easily grown.—S.

Orchids at Chelsea.—In the Orchid houses at Messrs. Veitch & Son's nursery may now be seen in flower a fine example of the lovely *Lælia elegans Turneri* bearing eight flowers from one sheath. The blossoms are large with a brilliant amaranth lip, the sepals are of a duller hue. *L. devoniensis* is another superb kind with smaller flowers than the last, but of a colour equally as beautiful. *Cattleya bicolor* and *Loddigesi* are fine autumn-blooming kinds and ought to be more generally grown. A fine variety of the Khasian *Vanda (V. coerules)* is gay with large racemes of flowers of a pale blue—a colour quite unique among Orchids. Amongst other attractive kinds are *Dendrobium formosum*, one of the finest of its section, and the beautiful Australian *D. bigibbum* with its variety *superbum*, which is, both in the size and colour of the blossoms, much superior to the type. The pretty *Lælia prestans*, a kind much in the way of *Cattleya marginata* and *Dayana*, is also finely in flower, together with other noteworthy kinds.

Ampelopsis Vitichi on the Thames Embankment.—This is very effective as seen growing over the tops of the walls along the Thames Embankment. Whilst the common Virginian Creeper has in most cases lost its leaves, at least in towns, this excellent close-growing variety will retain its cheerful and richly-coloured leaves for some weeks yet to come. Wherever bare walls in towns need to be covered this hardy climber cannot be too largely planted.—S.

Blue Cinerarias.—These are most acceptable just now, either in the greenhouse, conservatory, or window. Their flowers possess a colour which is especially scarce at this time of year, and if ar-

ranged in masses along with some of the newer kinds of zonal Pelargoniums, Chrysanthemums, &c., they would help to make a brilliant display, even at this comparatively flowerless season. We find abundance of them in Covent Garden Market, associated with Lilliums, Asters, and similar plants. In order to obtain Cinerarias thus early, the seed must be sown early in spring, and the plants must be grown in small pots only.—C.

Ivy Edgings.—Some of the Ivy edgings in London are very badly managed. In the picturesque garden or shrubbery the best way with an Ivy edging is to let it alone. In the trimly kept garden to do so is ruinous. If allowed to grow and then cut in several times the effect is very ugly. They should never be allowed in this case to grow strongly at all, but be pegged closely and regularly to the ground, and neatly and judiciously cut in once a year and pinched afterwards.

The True Water Melon.—We find good examples of this Melon in Mr. Garcia's shop in the Central Avenue, Covent Garden. They are round in shape, contain black seeds, and the flesh is very juicy and refreshing; very different to the oval-shaped, green and yellow Spanish Melons, of which there is now such an abundance in the markets. It is unfortunate that the true Water Melon does not appear in larger quantities earlier in the summer.—S.

The Blight of Statues in Dublin.—Dublin is beginning to suffer under a plethora of statues; some of them costly productions. If artistic or otherwise they are of little importance; they occupy space in important and crowded parts of the city, and lead to the expenditure of money which in this case would be better employed in the cleansing of what is in various parts the most foul smelling of cities, and that of which the death rate is so alarmingly high.

The Hesse Pear.—In seasons like the present this is probably one of the most profitable of market Pears, for if all other kinds fail this is almost sure to bear a large crop. The high aromatic flavour of the fruit is its chief recommendation, for its skin is tough, and its flesh, if allowed to become at all soft, turns mealy. Bushels of this Pear have been sold daily for some time past in Covent Garden at the rate of 2d. to 3d. per lb.—S.

The Embankment Trees.—The persistent rains and winds of the season have had no bad effect on the plants along the Embankment. They seem quite as happy as under their own clear summer sun. Every second tree ought to be removed this year. Damage often begins among trees before they seem to everybody to require thinning. The trees removed should be replanted elsewhere, and many places would be the better for such fine specimens, still young enough to be removed with safety.

Brunsvigia Josephinæ.—A fine specimen of this noble South African bulbous plant is in flower at the Pine-apple Nursery, Maida Vale. The flower-spike is 14 in. long, bearing a large head of flowers (about seventy) of a red colour, each one on a foot-stalk about 1 ft., making the cluster over 2 ft. in width. The plant was induced to bloom by being kept without water for seven months, until the flower-spike appeared, and doubtless by following a similar course the monster bulbs which are in the country could be made to flower equally as well.

The Round-leaved Catchfly (Silene rotundifolia).—This, one of the showiest of the North American *Silenes*, is finely in flower on the rockery at Messrs. Backhouse & Sons' nursery, York. It is nearly allied to the Royal Catchfly (*S. regia*) and to the Fire Pink (*S. virginica*), but the flowers are somewhat inferior in point of size to those of the latter species. They are, however, of the same brilliant scarlet hue, and the petals have deeply jagged margins, so that the outline of the bloom is not so symmetrical as in the others. It is a native of the shady banks of the Ohio and in Kentucky. Under culture it thrives on a rockery in a partially shaded position.

Michaelmas Daisies.—Mr. Stevens sends a collection of Michaelmas Daisies from his well-stored garden at Byfleet, among them being a bright and good variety called *Aster coccinea*, which is probably a variety of the New England Aster. There are some very good plants among these Asters, and we hope to figure some of them and enumerate the best kinds. There are also many weedy and indistinct species in cultivation, which would be better left in their native wilds.

The Closed Gentian (Gentiana Andrewsii).—Of this singular and rare species a fine specimen is now in flower on the rockwork in the Newton Nurseries, Chester. It has thirteen flower-stems, some 15 in. in height, and is bearing 140 blooms.—E. J.

Hardy Plants from Seed.—If the seeds of such hardy herbaceous plants as Larkspur, Columbines, Bellflowers, and Pentstemons be sown as soon as they are ripe, we get good plants before winter sets in, and many of them, too, will blossom the next summer. In fact, the fresher the seed is, the more readily will it germinate.—*American Agriculturist*.

THE FLOWER GARDEN.

GIANT GRASSES.

THE Grass family, besides being eminently serviceable to man by yielding so many useful products, is also rich in the possession of numerous stately habited plants. In cold climates the majority of them are herbaceous and of low stature, while in warmer regions they frequently become arborescent, with stems of perennial duration. The graceful proportions of many render them highly effective either as isolated specimens, or associated with the varied foliage of the shrubbery; and few subjects are more suitable for planting in the vicinity of ornamental water. In gardens having glass structures sufficiently spacious to accommodate plants of large size, several of the tropical Grasses might be grown with advantage, where their slender drooping foliage would have a striking effect. The hardy perennial species thrive best in a light moist soil, to which an occasional mulching of leaf-mould or decayed manure is added. The annual kinds, in order to obtain a fine development of their foliage, require to be sown early and treated similar to tender annuals before planting out. The places they are intended to occupy during the summer should be previously pulverised and enriched, and during the dry season they require frequent waterings, but a constantly wet condition of the soil should be avoided, or otherwise the foliage becomes sickly, and the inflorescence perishes before it emerges from the sheaths. The perennial kinds with creeping rhizomes are increased chiefly by division or by offsets, or, in the case of the branching sorts, by cuttings. The Sugar Cane, however, which rarely branches, may be propagated from the latent buds situated at the joints of the stem. Those that have a tufted rootstock are best increased by seeds, as they can seldom be divided so as to leave sufficient roots to sustain life on the detached portion. When it becomes necessary to transplant large clumps of the tufted kinds, such as *Gynerium* and *Arundo conspicua*, the places where they are to be planted should first be prepared so that they may be replanted with as little delay as possible, and in lifting them great care should be taken to keep the main body of the roots intact. The most suitable time for transplanting is between the middle of March and the end of April, at which season their growth commences and continues until the flower heads are developed. After this the plants remain inactive, and no more young foliage is produced until the following spring. Success rarely attends their removal at any other season, unless the soil be retentive and the greater part of the roots remain uninjured in the operation; but even then, the plant suffers from the check, which invariably causes the succeeding crop of flower-heads to be small.

The Japanese Eulalia (*E. japonica*).

Though ornamental Grasses are frequently recommended as eligible water-side plants, several, if planted in such positions, would require to be raised on mounds, so as to prevent their roots from coming in contact with a wet subsoil, which though it might be beneficial to them during summer, would, if combined with severe frost, prove fatal to them in winter. The flower heads of those intended to dry for winter bouquets or room decoration should be gathered just before flowering, as when left until later the spikelets break off in those kinds that have the florets connected by joints, and in the process of drying they should be kept in an erect position, so as to allow their branches to remain open, and not suspended head downwards, as other Everlastings require to be. The dead flower stems should be removed in the

autumn, but the basal tuft of leaves should in all cases be left until spring; though, should it succumb to the severity of the winter, it affords protection to the crowns. The dead portion, however, should be cut away previous to the young growth commencing, but not too closely—the stout bases of the leaf should remain permanent. Where the drainage is good, a covering of leaves is all that is necessary to protect the tenderer of those that die down in winter; but the evergreen sorts, when not sufficiently hardy to withstand the winter fully exposed, may be protected with mats fixed over stakes arranged in a conical form.

The number of Grasses at present in cultivation which exceed the height of 5 ft. is large, and among them there exists a great diversity in foliage and habit, the most desirable of which are included in the subjoined selection:—

The Bulbous-rooted Panicum (*P. bulbosum*).—The Panicums are widely distributed in all except the very coldest climates. This species is a native of Mexico, and attains the height of from 6 ft. to 8 ft., and has light green, narrow, arching leaves upwards of 2 ft. in length. The flower-stalks, which rise well above the foliage, bear conical branched clusters, which are from 12 in. to 15 in. in length. The branches have an upward tendency, and the spikelets are of a reddish-brown. The bases of the stems are swollen, a character which gives rise to the name. It requires a light and rather dry soil.

Large Panicum (*P. maximum*).—This has more slender foliage than the preceding, but under similar conditions exceeds it in height. The leaves are glaucous beneath, and are produced very near to the panicles, which have hair-like drooping branches with light brown spikelets. This is also known as Guinea Grass.

Plaited-leaved Panicum (*P. pllicatum*).—Though sufficiently hardy to live in the open air during summer, it requires

a stove temperature to develop its superb foliage. Under these conditions it attains the height of from 6 ft. to 7 ft. Its leaves are lanceolate, and from 12 in. to 15 in. in length, and about 3 in. broad in the widest part, with prominent ribs. The foliage is covered thickly with dense short hairs, which causes it to feel soft to the

Large Horse-tooth Maize (*Zea Mays* var.)

touch. Each leaf is ornamented with a distinct white line down the centre. The panicles are slender with spikelets of a greenish-white.

Deep-veined Panicum (*P. nervosum*) is a taller-growing plant than the preceding, with much longer and narrower leaves, of a brighter green. The plant is quite destitute of bristles, but the margins of its leaves are armed with fine teeth. In the young state this and the preceding make useful decorative plants.

Millet Grass (*P. miliaceum*).—This is a showy annual Grass, growing to the height of 5 ft. to 7 ft., with a stout, branched, hairy stem. The leaves are of a light green, with wavy margins and recurved points. The panicles, which are produced both terminally and laterally, have numerous slender pendulous branches, bearing a great weight of roundish spikelets, which are of a very ornamental character when ripe. It is a native of East India, and requires a well drained soil.

Japanese Eulalia (*E. japonica*).—The typical plant, as shown in the figure, frequently attains the height of 7 ft., and forms a fine tuft of erect stems, which are furnished with foliage from the ground to the extremities. The leaves, which are from 3 ft. to 4 ft. in length, and rather less than 1 in. in breadth, are rigid and channeled with a conspicuous white groove down the centre of each. In colour they are dark green, with a purplish tinge above, and glaucous green with a few silvery hairs beneath. The flower-heads are fingered, and dark brown when they emerge from the sheaths, but as the numerous hairs around the spikelets expand, they become grey and feathery. The varieties of this plant are not so robust as the type, but they are nevertheless quite hardy. The striped form has very often in addition to the white lines, others of a purplish tinge, and has usually very dark purple sheaths. The yellow-barred variety, *E. zebrina*, may prove to be specifically distinct from the foregoing, as it differs in having a more tufted habit of growth, and hairy leaf sheaths with no traces of a purple tinge. They may be used with advantage either as stove or conservatory plants, where their variegation, from being protected, is much more clearly defined.

Erect Erianthus (*E. strictus*).—This is an erect-growing plant rising to the height of 6 ft. Its leaves are linear, and from 2 ft. to 3 ft. in length, with recurved points; they are of a dull purplish-green, with a white or sometimes violet midrib. The stem and leaf-sheaths are of a dark purple, and the panicle, which are dark brown and oblong when first produced, afterwards expand and change to a cinnamon colour. It is a native of the United States.

Slender Erianthus (*E. Ravennæ*).—This forms a tuft of slender, reddish foliage, above which arise numerous erect flower-stalks bearing an inflorescence similar to the *Eulalia*. The leaves, which taper to both extremities, have a whitish, grooved midrib, and are clothed with silky hairs at the base near the sheaths. It requires a warm, light soil, and in favourable situations it reaches the height of 6 ft. It is a native of South Europe and North Africa.

Broad-leaved Gymnothrix (*G. latifolia*).—This is a most luxuriant Grass, forming large tufts of dark green foliage. The stems and leaf-sheaths are of a rich purple. The leaves are from 2 ft. to 3 ft. in length, and from 1 in. to 2 in. in breadth, and droop gracefully. The panicles, which are rarely seen in our climate, are of a purplish-brown, with drooping branches. It is a native of La Plata.

Perennial Millet (*Sorghum halepense*).—This is one of the most accommodating of hardy Grasses, thriving almost anywhere. It grows to the height of 5 ft. or 6 ft., with erect stems, and copious light green foliage. The leaves, which spread horizontally, have a white midrib, wavy margins, and drooping points. The panicles,

Great Reed Grass (*Arundo Donax*).

which are reddish-brown, are very conspicuous, and rise above the foliage. It blooms in October, and is indigenous to South Europe.

Dawa Corn (*Sorghum vulgare*).—This annual is one of the principal grain plants of Tropical Africa, and grows to the height of 5 ft. to 6 ft. It has a simple, erect stem bearing numerous light green, channeled leaves, and a terminal tufted panicle. The grain is enclosed in shining brown husks, which give the plant a singular appearance.

Maize or Indian Corn (*Zea Mays*).—Among the annual Grasses this deserves a prominent place, on account of its stately habit and robust, wavy foliage. When well grown the stems reach the height of 6 ft. or 7 ft., and are terminated by a plume of male flowers. The forms of this plant are very numerous; the variegated ones are employed extensively for outdoor decoration, but it varies considerably more in the form and colour of its grain. Our figure represents the Large Horse-tooth Maize, so called from a fancied resemblance of its grain to a horse's tooth. It however bears the largest spikes of corn, and attains the greatest dimensions of any of the varieties.

Luxuriant Reana (*Reana luxurians*).—This, although a perennial in the Tropics, where it is grown as a fodder plant, is only of annual duration in this country, and thrives but indifferently when grown in the open air, except in very favourable localities. In a stove temperature it forms a noble object, often attaining the height of 15 ft. Its leaves, which are usually from 3 ft. to 4 ft. in length and 2 in. in breadth, are light green, wavy, channeled, and recurved. The flower-spike, which resembles that of the Indian Corn, is produced in the axils of all the upper leaves. The stigmas protrude beyond the sheaths, and resemble red, silky tassels.

Gigantic Jungle Grass (*Androsceopia gigantea*).—This is a stately Grass, common to the islands of Polynesia. It forms a dense tuft of bluish-green foliage, which is from 8 ft. to 10 ft. in height. The leaves are from 6 ft. to 8 ft. in length, exclusive of the sheaths, which clasp each other at the base, and present a similar arrangement to the leaves of an Iris; they are deeply grooved and very rigid, with finely serrated, sharp edged margins; the stems send out a number of lateral branches, which produce a quantity of aerial roots at their point of attachment. The inflorescence resembles a gigantic cluster of Oats intermixed with scaly leaves. It is not sufficiently hardy to plant out-of-doors, but it is very attractive under glass.

Job's Tears (*Coix Lacryma*).—The small, roundish, slate-coloured beads, known as Job's Tears, are the fruits of this plant. It is a stout, erect-growing Grass, with light green, grooved, drooping leaves, from 2 ft. to 3 ft. in length. The stems often attain to a great height; in the variety *C. gigantea* they sometimes measure 20 ft. The leaf sheaths and stems are covered with a white, mealy powder. If treated as a tender annual it thrives in the open air in summer. Its flower-head consists of racemes of three to five spikelets, which hang from the axils of the upper leaves.

Sugar Cane (*Saccharum officinarum*).—None of the Saccharums are sufficiently hardy to withstand our winters, but those enumerated here make fine ornaments in the open air during summer.

The species under notice grows to the height of from 15 ft. to 18 ft. in a stove temperature. Its leaves are arranged alternately on opposite sides of the stem, as in *Arundo Donax*. There are several distinct forms with variously coloured stems, some of which are of a dark purple, while others are distinctly striped. In a young state, they are all attractive on account of their graceful arching foliage.

Batavian Sugar Cane (*S. violaceum*) is a densely tufted plant with purplish or violet foliage, with a conspicuous white groove down each leaf. It is a much dwarfer plant than the preceding, seldom exceeding 7 ft. or 8 ft. in height. It thrives best where its roots can be immersed to a depth of a few inches in the water of a stove tank.

Egyptian Sugar Cane (*S. ægyptiacum*).—This, as will be seen from the annexed engraving, is a plant of elegant appearance. It attains the height of 6 ft. or 8 ft., and is of similar habit to the preceding, but its foliage is of a brighter green, and more stiff and hairy. It withstands the mild winters of Southern Europe, but it is too tender to bear the severity of our climate; it might, however, be employed in the open air in summer and receive the protection of a house in winter.

Pampas Grass (*Gynerium argenteum*).—Several varieties of this well known Grass have been introduced or raised at home which are superior to the typical plant. This kind bears male and female flowers on separate individuals; of the white varieties the female plant is a more desirable one than the male, as its plume is of a more silky texture, and expands after drying, whereas the male cluster is more stiff, and closes in the dried state. Of the pink or earmine varieties, the male plant exceeds the female one in dimensions. The variety *G. nanum* is a very desirable one, as it is more compact in habit, blooms earlier, and partakes of the character of *Arundo conspicua*.

Early-flowering Pampas Grass (*G. jubatum*).—This is a

recently-introduced plant from Chimborazo, and is not quite so hardy as *G. argenteum*. Its panicles are of a creamy-white, and it blooms early. In habit it is similar to the foregoing, but its foliage is of a brighter green and its sheaths are pubescent.

White Rosseau (*G. saccharoides*).—This produces the finest flower-spikes of any known Grass of the herbaceous type, as they frequently measure 5 ft. in length, are somewhat conical in outline, and are about 1 ft. in diameter at the base, consisting of numerous whorls of grey feathery branches, which have a tendency to droop to one side. It is a true aquatic, but quite different in character from *G. argenteum*; instead of forming a dense tuft of leaves at the base, it partakes of the character of *Eulalia japonica*, and reaches the height of from 12 ft. to 15 ft. Its leaves are narrow, deeply grooved and recurved, and have sharp toothed

Egyptian Sugar Cane (*Saccharum ægyptiacum*).

margins. It is a native of the West Indies and Brazil, and for its full development it requires a stove temperature.

Great Reed Grass (*Arundo Donax*).—This and the following are the most distinct of our tall hardy Grasses; the glaucous hue and peculiar arrangement of their leaves, combined with their robust character, render them strikingly effective objects, especially if situated so as to have a background of darker foliage. This species, when well grown attains a height of from 8 ft. to 10 ft. It rarely blooms in this country, owing to its growths being seldom matured. The variegated leaved form is a more delicate plant, and thrives best indoors.

Mediterranean Reed Grass (*A. mauritanica*).—This is a more slender plant than the foregoing, and produces more young growth from the base; it has the peculiarity also of becoming variegated when removed from a wet situation into dry poor soil. Its panicles are larger than those of the preceding, being as much as 2 ft. in length and from 8 in. to 10 in. in breadth, with spreading branches and greenish spikelets. It is a true aquatic Grass, but not quite so hardy as *A. Donax*.

New Zealand Reed Grass (*A. conspicua*).—This, though not quite so hardy as the Pampas Grass, is more suitable for some places on account of its dwarfer growth. It also blooms as early as August, a character which greatly enhances its value. It requires a well-drained, rather dry soil, and in this respect, as well as in outward appearance, it differs from its congeners. C. M.

AMERICAN LILIES.

WE have, east of the Mississippi, four admitted species of native Lilies, three of which are common throughout the Northern States, and one southern species. These four are naturally divided into pairs, and in two of them, the parts of the flower which commonly pass for petals, are narrowed at the base to form a sort of stem, or claw, as it is termed botanically. These two are the "Wild Orange-Red Lily," (*Lilium philadelphicum*), and the "Southern Red Lily," (*L. Catesbaei*). In these the stems are about 2 ft. high, the flowers are erect, and bell-shaped; the first named has two or three on the stem, reddish-orange with dark purple spots on the inside; the other has a single flower to the stem, which is almost scarlet, and spotted with purple on a yellow ground. The other two have nodding flowers, with the parts not narrowed below, but are turned back, like those of the "Turk's Cap" Lilies of the gardens. Of these two the "Canada," or "Wild Yellow Lily," (*L. canadense*) is from 2 ft. to 5 ft. high, with a few orange-coloured flowers, with brown spots. The "American Turk's Cap Lily," (*L. superbum*), grows 3 ft. to 7 ft. high with a pyramidal cluster of many—sometimes 20 to 40—flowers bright orange-red in colour, with many dark purple spots on the inside. Besides these, there has been described the "Carolina Lily," (*L. carolinianum*), with few and yellow flowers, but otherwise so like the last named, that it is usually regarded as a variety of it. Of these wild Lilies, the first two are most generally found in sandy ground, while the other two grow in rich moist meadows and low grounds. With the exception of the southern species, they are not at all rare, and some, if not all, may be found in most localities. To those who are fond of cultivating flowers, these offer many attractions; the bulbs may be transplanted with great ease, and in the rich soil of the garden, where they have not been forced from necessity to struggle against a crowd of other plants, they present a luxuriant growth and an abundance of flowers, such as is rarely met with in a wild state. Not only do they vary considerably in the number of flowers and their size, but they present a marked variety in the colour, in the wild state. Our Lilies puzzle botanists. We have stated as to the last one, named *L. carolinianum*, that it was regarded as distinct from the "Turk's-Cap" (*L. superbum*) by some, while it is, by our best authorities, placed as a variety of that. But a greater difficulty presents itself; plants will occur so evenly between the "Canada Lily" and the "Turk's-Cap," that it is difficult to say to which they belong, and some doubt if the two are really distinct, and if the main difference is not after all one of luxuriance of growth. When it comes to the question of colour, the wild plants show the greatest variety. The "Wild Turk's-Cap" is usually described as having orange-red flowers; we have seen them when scarlet, and a deep scarlet would best describe the colour. We recently saw in the grounds, of Woolson & Co., Passaic, N. J., a row of this Lily (*Lilium superbum*) containing some hundreds in full bloom. These were from bulbs dug up in the country round about there, and the variety they presented was most interesting. Some plants were not over 2 ft. high, while others were nearly 6 ft. and in the number of flowers to the stem, the size of the individual flowers, and especially in their colour and markings, there was sufficient variety to induce some botanists to make many species. While we had seen here and there a few bulbs of our native Lilies under cultivation, we never before

saw them by the hundred, and we were more strongly than before impressed with the great beauty of these natives of our meadows and bogs, and the inducements they offer to lovers of flowers to bring them into cultivation. By careful selection, marked varieties may be obtained, and to those who would experiment with seedlings, and especially in hybridising, they present a field in which the amateur may reap rich results. Upon the western side of the continent there are species of Lilies resembling ours, and besides these several, such as the Washington and Parry's Lilies, quite unlike our eastern kinds, and more resembling the exotic species. Among those closely related to our eastern Lilies is the Columbian Lily (*L. columbianum*). This, which has been thought to be merely a form of our Wild Yellow Lily (*L. canadense*), is now regarded by Mr. Sereno Watson, who has given special study to the genus, to be a good species. It is the common Lily of the northern portions of the Sierra Nevada, and is, as yet, but sparingly in cultivation. It grows from 1 ft. to 2 ft. high, and has whorls of very distant leaves. Its flowers, from two to five in number, are very small, being only about 1½ in. across, with the parts turned strongly backwards; orange yellow freely spotted with purple. This is an exceedingly neat and interesting dwarf kind, which we hope may soon be in general cultivation.—*American Agriculturist*.

NEGLECTED HERBACEOUS PLANTS.

Spiræa Aruncus.—This old-fashioned plant is seldom met with now-a-days; but I was agreeably surprised to find that a young lady, who took the first prize for dinner-table designs at a horticultural show in one of the most fashionable towns in the kingdom about a dozen years ago, had made this *Spiræa* the principal feature in the design, and it was at the time very generally admired, and by many supposed to be something new. It is, however, a very old plant, but one which is often pushed aside into some obscure background. It well deserves being brought forward. It grows about 3 ft. high, and looks well in the distance as well as on closer inspection.

Spiræa venusta.—This is also but seldom met with, although it well deserves attention, as it is of a beautiful rosy-purple colour, and I have always found it to thrive and do well, while I never could succeed with *S. palmata*, which I suppose was intended to supersede it, but either the soil or something else did not suit it here, so I lost it two or three times, and ceased trying to grow it, while *S. venusta* always flowered and looked well. It is rather taller than *S. Aruncus*, and in some respects resembles the wild Meadow Sweet, except that the colour, as above stated, is rosy-purple.

Spiræa filipendula plena.—This, I presume, is still generally cultivated, as it is one of the prettiest plants we have, and its foliage is also neat and pretty. It is not so tall as the others just named, being about 18 in. or thereabouts in height. It is a fine plant from which to cut flowers, and one that is, while growing, neat looking and ornamental.

Golden-leaved Spiræa Ulmaria.—Many years ago I had a variety of the common Meadow Sweet with foliage beautifully marked with gold-coloured veins or markings, which it seemed to retain year after year with more regularity than many variegated plants, and this peculiarity of its foliage rendered it a fit companion for exotic plants. Although it was quite hardy, and used to come up regularly in the common ground, it was also a favourite in pots. I do not think it is very common as I seldom meet with it elsewhere.

Phlox Van Houttei.—This, though perhaps not so old as some of the plants mentioned above, is, nevertheless, not a plant of recent introduction, as I was acquainted with it about 1849, and I think it has since received the attention which it deserves, being neat in habit and not too tall; in fact, it seldom grows more than 2 ft. high, and the flowers are as correctly striped red and white as the choicest Carnation ever is when in its best form, while it is so prolific of flower, that I think it must have sprung from *Phlox omniflora*, which is but seldom met with now-a-days. Its flowers are beautiful in bouquets, and altogether it is a plant that well deserves cultivation.

Double Yellow Rocket.—This, I believe, is not a Rocket at all—certainly not a *Hesperis*; but in olden times it used to be called the Yellow Rocket to distinguish it from the white and purple, both more plentiful fifty years ago than they are now. It seldom grows more than 1 ft. high, and, I believe, likes moisture. It is well worth looking after.

White and Yellow Batchelor's Buttons.—These, though sometimes met with, are not so plentiful as they ought to be, the white especially being very scarce, while both are, or rather were,

great favourites with our grandfathers, as were also several other plants which I cannot at the present moment call to memory; but I am pleased to see that an interest in such matters is reviving.

AN OLD GARDENER.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Anemone japonica Honorine Jobert.—For autumn there is no more useful plant than this, and all gardens, and green-houses too, should contain large stocks of it. If planted in a rich soil, and left undisturbed for two or three years, it grows into large masses, throwing up hundreds of beautiful white flowers on tall, slender, branching stalks, and remains thus with a continual succession of bloom, for a whole month. For greenhouse purposes we keep a stock of good-sized plants of it in the reserve garden, potting them when the buds are well formed, and then place them in the conservatory or cool greenhouse, where they bloom very freely, and are even more beautiful than those in the open ground. By a little arrangement it is easy to have these Anemones in flower in the conservatory for nearly two months. For those who do not know this lovely flower, I would describe it as being like a very large Wood Anemone, growing from 3 ft. to 4 ft. high, and bearing from a dozen to twenty flowers on each stalk. As regards purity and beauty it is fit for a bride's bouquet. For dinner-table decoration it is also exceedingly useful, either in pots or in the shape of cut blooms. The latter last fully a week in water if cut when freshly opened. It is perfectly hardy, needs no skilful cultivation, and is cheap. We tried a long line of this Anemone planted alternately with *Gladiolus bronchleyensis*, but the *Gladiolus* was over before the Anemone was in its full beauty.—BROCKHURST.

Mixed Herbaceous Beds.—There has been no grander feature in the grounds at the Crystal Palace this year than the large mixed herbaceous beds on the lower terrace garden. They are composed of fine masses of the scarlet *Tritoma Uvaria*, the showy yellow-flowered double *Helianthus*, big bunches of *Phloxes* and *Asters*, and specially the marvellously fine heads of the beautiful magenta-coloured *Sedum spectabile*, which makes such a grand decorative plant at this time of the year. Beside these noble mixed masses rigid designs in Golden-feather and clipped *Mentha* are tame and formal. Of tender plants, the beds of *Dahlias* are also most effective; and certainly worthy of copying in every large garden are the very pleasing combinations in dwarf ornamental shrubs, that are beautiful not merely to-day, but permanently so for many years to come.—A. D.

Hypericum calycinum under Trees.—The notice in THE GARDEN (p. 276) of the Fern glades in Penrhyn Castle reminds me of the manner in which this St. John's-wort was treated in the same place some years ago. All the bare places and what would otherwise have been brown unsightly patches under the trees, from the hedges up to the Castle, were planted with this *Hypericum*. An old name (at least, a local one) for this plant is Park Leaves, and certainly in those days, as seen from the approach, it gave the park quite a character. No shade seems too deep for this plant to thrive under, and, to say nothing of its very conspicuous handsome flowers, its broad masses of ample foliage, growing where a Moss would scarcely exist, render it valuable, even more so than any for such places. This plant is also known in the North of England as the Rose of Sharon, and it is just the plant adapted to make the wilderness blossom as the Rose.—THOMAS WILLIAMS, Ormskirk.

The *Nymphæa alba rosea* (more correctly, it seems, *N. alba rubra*), figured in our last volume, has been named *N. Caspary* by M. Carrière, who has also published a figure of the plant in the "Revue Horticole" (1879, p. 230). The plant has had a variety of names; thus Prof. Caspary, of Königsburg, called it *N. alba sphaerocarpa rubra*, and M. Duchartre, *N. sphaerocarpa rubra*. Whatever name it bears, it is, as M. Carrière observes, a very fine plant. According to the account given, it is a variety of *N. sphaerocarpa*, a plant nearly related to *N. alba*, but distinguished by its more rounded fruits, the present variety differing in the carmine rose colour of its interior petals. It is described as being vigorous and hardy, with large, slightly undulated leaves almost entire at the edge, and attached by red petioles; the peduncle large, ferruginous, the buds red, the flowers tender rose, often somewhat veined with violet. It commences to flower in June, and continues flowering almost until the frosts. It was discovered in a lake near to Tweden, village Kamna, near Nerika, in Sweden, in 1856. According to M. Frébel, it is a very floriferous plant, commencing to bloom eight or ten days before *N. alba*, is completely hardy, and requires the same culture as *N. alba*. He adds that it reproduces itself from seeds, but M. Carrière wisely observes that those who wish for a perfectly true stock should

increase it by division, reserving the seeds for the production of varieties, of which some might chance to be deeper in colour than the parent. It will be a great acquisition for the embellishment of our ornamental waters.—"Florist." [Of this a coloured figure is given in THE GARDEN, Vol. XV., p. 516.]

Chilian Beet.—This has been most effective during the present season, making unusually vigorous growth, and is extremely well coloured, varying from creamy yellow to a brilliant red in the stalks. When planted as an edging to beds of sub-tropical plants of taller growth, such as *Canna*, *Castor-oil* plants, &c., they are much more effective than in a mass, as the leaf-stalks are then seen to advantage, being much more highly coloured than the leaves. Being comparatively hardy, they continue to be effective plants after the first slight frost has cut down their more tender companions.—J. G. L.

Japanese Privet (*Ligustrum japonicum*).—This makes a most useful shrub for single specimens on Grass or in the shrubbery borders. It is now in fine bloom with us, its deep green shining foliage shows its load of pure white flowers to great advantage. Beyond losing some of its leaves it withstood the last severe winter with impunity, and should therefore prove hardy, except in extremely unfavourable situations.—J. G. L.

Acanthuses in the Wild Garden.—I find these handsome foliaged hardy plants quite at home in the "wild" garden, for, when once planted they soon extend into large clumps and become quite naturalised. For clothing banks, &c., they are admirably adapted, as they grow freely in any kind of soil, and luxuriate in sunshine or shade, so that they adapt themselves to any position. The bold yet gracefully formed foliage being of an evergreen character, and cut down only by severe frost, renders them most useful plants for giving a cheerful look, when plants of a deciduous character have died down.—J. Groom.

Erigeron mucronatum.—This pretty Composite, which is also known as *Vittadenia triloba*, has proved itself an excellent plant for growing on old walls. It thrives equally well as *Erinus alpinus*, &c. Self-sown seedlings have appeared in several places as much as 50 ft. away from the parent plant. Such a continuous blooming plant will be very welcome I am sure in such positions. *Jamesia americana* also appeared on the back wall of a low cold pit as a self-sown seedling, and grew into a vigorous plant, evidently quite at home in the Moss and old mortar between the bricks.—T. SMITH.

The Old Double White Rocket.—"R. D." (p. 295) ought to feel proud of his plant, the true old double white Rocket—a truly beautiful flower fast becoming extinct. This plant has always been pre-eminently a cottage garden flower, and fifteen or twenty years ago its cultivation, and consequently its sale, among the cottages in many parts about here was enormous, many of them paying their rent with it; but it disappeared all at once, and I knew not where a plant could be obtained. It is a very old plant, having been introduced into England 300 years ago. Strange to say the type (*Hesperis matronalis*) is seldom or never met with—I mean in the single state. Whoever may possess this plant and may wish to increase it, the secret lies in not letting it flower. As soon as the flower stem is formed, pinch it off; laterals will spring from the base, and these, with the heel retained, will make the future plants. What is known as the French or Giant variety appears to be a different kind, and the crimson and purple sorts are apparently forms of it, though I believe *H. matronalis* is purple. There was at one time a green-flowered variety in existence—of course, like the double white in question, a monstrosity. However, seeing the plant has sported from purple to white and double white, it is possible that "R. D.'s" new dwarf purple and new crimson may be reversions to the type as regards colour. There is also what is known as the yellow Rocket, a double-flowered form of *Barbarea vulgaris*, a handsome plant, but not a Rocket; and what is known as the red Rocket, another pretty neat plant, is *Lychnis viscaria*, also with double flowers.—THOS. WILLIAMS, Ormskirk.

Schizostylis coccinea.—This very useful plant should be grown in quantity wherever cut flowers or decorative plants are in request during the winter months. It is perfectly hardy, and will flower out-of-doors in a mild autumn, but to obtain the flower in its full beauty it should have some protection from inclement weather. A quantity was planted out here in spring in bunches in well-prepared soil; they are now ready to lift for potting or furnishing boxes, stands, &c. They are very accommodating plants, as they may be safely transplanted at any time. If, when planted close to a wall or fence, some temporary protection can be given from severe frosts, a good row will yield a large quantity of spikes for cutting purposes. As bright colours are so valuable during the dull days and not procurable from many outdoor plants at that season, it is surprising that this beautiful Irid is not more generally grown.—JAMES GROOM, Linton.

Aponogeton spathaceum var. junceum.—In the note (p. 299) on this plant having flowered at Kew, no notice is taken of what I consider its most peculiar feature. The flowers are borne on erect stems, 3 in. or so above the water, and as soon as fertilisation has taken place, the stems bend over like a shepherd's crook, so as to place the flower head below the surface. Something analogous occurs with the commoner plant *A. distachyon*, the flowers of which are often thrust up above the water's surface, but as soon as fertilisation has taken place, the stem sinks altogether, so as to bring the flower-head down to just below the surface. This fairly illustrates the fact that all plants possess the power of adapting themselves to their peculiar circumstances. *A. distachyon*, being a deep water plant, and so able to accomplish its end in one way, whereas *A. spathaceum*, being a shallow water plant (its point of immersion being about 2 in.), cannot so act, and so adopts a different course.—T. SMITH, *Newry*.

—The singular twisted appearance was shown fairly well in the woodcut; in the absence of which allusion would have been made to it. The peculiar tendency of the flower stalks to submerge after fertilisation is by no means a permanent character, as I have had ample means of observing in the scores of plants that have flowered at Kew. I have obtained matured seeds from quite erect stems which showed no tendency to turn whatever. The limit of the depth also is by no means a fixed one, though I found that a depth of 2 in. was the most suitable depth during summer, after experimenting with several hundred plants. In winter I found that those which were wholly submerged kept in the most thriving condition, whilst those in shallow water died down to the surface. It is found naturally in very wet places, growing amongst Grass and other herbage, which no doubt protects it very considerably.—W. G.]

Sweet Peas in Pots.—The finest Sweet Peas in pots that have yet come under my notice were sown very early in the year in 8-in. pots, and, when grown to the size when more space was required, they were shifted on into 13-in. pots, and had stakes about 5 ft. high placed round them for support. As soon as the leading shoots pushed outside the stakes the points were nipped out, and it was this pinching, with the copious supplies of liquid manure applied to them, that induced them to grow so strong and produce a thicket of flowers. When Sweet Peas are well cut back during summer, several shoots will spring from the point where the one shoot was cut from, almost causing the plants to assume a somewhat perennial character, and if well supplied with water, with an occasional dose of diluted liquid manure, they are less inclined to produce seed-pods, and consequently there is nothing to exhaust them or check flowering until the cold autumn nights come. By the robust growth and abundance of flowers they produce this season, it is evident that they are moisture-loving subjects.—E. HOEDAY.

Campanula pyramidalis Hardy.—I am glad to see attention drawn to this fine herbaceous plant (see p. 298), and I can endorse the statement that this noble Campanula is perfectly hardy. It has been here—in North Yorkshire—in an open border for two years, and is now flowering profusely, many of the plants being 5 ft. in height. The *Astilbe rivularis* makes a fine background for this noble flower. It has a fine effect when planted in lines, with a central of one white, and blue on each side. Planting deeply injures the fleshy roots of this Campanula. I plant it shallow, and put a spadeful of sand over the roots.—CHAS. DONALD, *Stokesley*.

Rosa Regellana.—A beautiful feature in this Japanese Rose which I have not seen alluded to is the change of the leaves in autumn to a bright golden hue, a specimen of which I enclose. I see that the leaves of another Japanese plant (*Aralia japonica*) are about the same colour.—GEORGE F. WILSON, *Heatherbank, Weybridge*. [The leaves sent are indeed very beautiful, and where large bushes of this kind are seen they must be highly effective.]

Browallia elata in Open Borders.—Although usually grown as a pot plant under glass this is useful for open borders, as blue flowers are comparatively few. I planted out many in an exposed situation, and although the season has been anything but favourable for plants of a tender nature, they have grown away freely, and continued to produce their pretty blue flowers in abundance. As it is easily grown and very floriferous, I can recommend it either for growing in pots or for borders.—J. GROOM, *Linton*.

The Alpine Snapdragon (*Linaria alpina*).—This charming little plant has been flowering almost incessantly for the past three months on the rockwork in the Newton Nurseries, Chester, where it has been the admiration of all who have seen it. On large rocks, where this little gem may be left to seed year after year, it would form a most pleasing and attractive feature.—E. J.

Sedum Telephium purpureum.—This Stonecrop has produced a fine mass of bloom during the present autumn; never have I seen the heads finer or the colour richer. Apart from its great beauty as a decorative plant, it is specially interesting for the attrac-

tions the flowers offer to numerous insects, including gaudily-hued butterflies, which are doubtless attracted by the gay flowers.—A. D.

Tricyrtis hirta nigra.—A good quality in this plant, which is noticed at page 298, is, that it blooms about three weeks earlier than the type, and therefore in time to escape frost; it is also a free seeder. With us *T. hirta* proves perfectly hardy, but the blooms are annually damaged by frost. It makes a capital orchard house plant.—GEORGE F. WILSON, *Heatherbank, Weybridge*.

Hyacinthus candicans.—Some very large bulbs of this beautiful Hyacinth have proved themselves to be quite hardy in the Newton Nurseries, Chester. They were left out in the open air during the whole of last winter in pots plunged half their depth in coal ashes. On one plant I counted some forty flowers and buds, the stem being over 5 ft. in height.—E. J.

THE KITCHEN GARDEN.

CULTURE OF WINTER GREENS.

In the winter season we rely mainly upon the Cabbage tribe to furnish our supply of fresh vegetables. Generally our climate enables us to enjoy green vegetables the whole year through, for we seldom experience a winter severe enough to destroy them, and I have often thought that the advantages which we derive in this respect are not fully appreciated; and yet we seldom find that ample provision is made in order to secure a supply of such kinds as Brussel Sprouts and Savoys. This shortcoming is especially noticeable in small gardens. In large establishments special attention is generally devoted to this branch of vegetable culture. The culture of winter greens is not attended with any great difficulty, success depending chiefly on having rich soil well stirred, combined with strict attention to cleanliness, and copious waterings in hot weather.

Coleworts.—These are very acceptable in the winter on account of their tenderness and delicate flavour. In severe weather they need some slight protection; the best way of affording it being to lay them in closely in some sheltered place, covering with Bracken or litter of some kind. Sow the seeds the first week in July in drills which have been previously moistened, and cover up till germination takes place. Plant out in rows 18 in. apart, and fifteen in the rows; keep them well watered till fairly established, and dress several times with soot, using the hose freely amongst them. The brown grub is apt to be troublesome, and must be watched for and destroyed when seen. Early York and Early Imperial are good kinds. Rosette is a smaller well flavoured sort, that may be planted rather more closely.

Savoys.—Where a large supply of winter vegetables is required the Savoy will be found invaluable; it may either be used when fully grown or in the form of Coleworts, in which state it is more delicate, but, of course, not so economical as when fully developed. Plant out in rows 20 in. apart, and 18 in. from plant to plant; the smallest plants put in later and more closely will furnish Coleworts. Rich ground and plenty of manure water in hot weather are necessary to bring this vegetable to perfection.

Brussels Sprouts.—This vegetable is often considered somewhat of a luxury. Why this idea prevails it is hard to say, as its culture is as simple as that of ordinary Cabbage. It certainly requires high culture, under the influence of which it becomes quite as profitable a crop as any. Sprouts may be had the whole winter through. The seed should be sown in March and the young plants pricked out in a bed of free soil. From this they should be transplanted to deep and well-manured ground. The beds should be frequently hoed during the season, and an occasional dose of manure water will assist them to make vigorous growth. It is useless to attempt to grow them on poor, impoverished ground, and it is owing to this that many consider them an unprofitable crop.

Borecole or Kale.—This is the most popular of all winter Greens, and, on account of its coming to perfection in ordinary soil and without any special care, is largely grown by cottagers. The tops may be cut during the winter, and sprouts will be formed the ensuing spring. It is a hardy and profitable vegetable, and should be grown in every garden, as in severe winters, when the tender kinds of vegetables are checked, it will be a source of supply. Sow in March, and prick the young plants into an open bed. Transplant them into rows 2 ft. apart, and 16 in. between each plant. They should be grown in a breezy, sunny situation, as they then become starchy and hardy, and form good heads.

J. C.
Byfleet.

PURPLE BROCCOLI.

Owing to the better appearance which the white and sulphur-coloured Broccoli present at table, the purple sorts have never been so popular as they deserve to be, for, as regards flavour, none of them are second to the white varieties, whilst the Early Purple Cape and the Late Dwarf Purple (of which the annexed is an illustration) are of the finest flavour and very hardy. The Early Purple Cape is one of the best of all the kinds of autumn Broccoli, as it never fails to become fit for use at the right time. A sowing made the first week in May ensures a supply of fine heads from the middle of September, and, if another sowing were made at the end of the month, the supply would be continued into November. The Mottled Purple Cape is another excellent variety, and a good mid-season kind; in colour it occasionally varies from greenish-purple to bright pink, and is, as its name implies, occasionally mottled. It should be sown about the last week in May, and will then be fit for use during the latter part of November and December. The Late Dwarf Purple is in every respect excellent. It grows from 12 in. to 15 in. high. Its leaves are dark green, short, deeply indented, and toothed. The heads, which are small and compact, are in colour the deepest purple, and they are fit for use in April if the seed be sown about the middle of May. The next variety—Purple Sprouting—is better known than any of the foregoing, being a general favourite for winter and early spring use, and certainly a more profitable winter green than it is has not yet been introduced to our gardens. In good soil it attains a height of 3 ft., and produces a profusion of

The Late Dwarf Purple Broccoli.

sprouts from within a few inches of the bottom, not the least of its merits being that the leaves and midribs of the same are as tender as the flowering sprouts. If a couple or three successional sowings be made from the beginning to the end of May, a succession of sprouts may be had from December to March. The above are the best, but other excellent coloured kinds are Dancer's Late Pink Cape, Purple Silesian, and Siberian. W. W.

LAYERING BROCCOLI.

With the experience of the last severe winter still impressed upon us, I think it will be well to prepare as far as possible, lest a similar season is in store for us, and again damage our green crops. Owing to the wet sunless season, Broccoli especially is in a condition to suffer badly should severe weather suddenly come upon it. A succession of extremely mild winters had, previous to the last, brought the practice of layering Broccoli into disrepute, and doubtless if we could ensure their immunity from frost, it would be best to leave them undisturbed. Where for want of space it is absolutely necessary to plant Broccoli and Winter Greens between other crops they are much more liable to get drawn than if allowed ample space in open airy positions where the tissues become firm from their earliest growth. This is the reason why such crops so grown withstand frosts, whilst they destroy those in sheltered walled-in gardens. As a crop of only moderate sized heads is required in most private gardens, I advise any one having luxuriantly grown crops of Broccoli, of sorts that do not come fit for use until the spring, to layer them at once by taking out a little soil on the north side of the plant and laying them down, and then packing the soil well over the stems in order to protect them. They will at this season soon recover the partial check, and will safely withstand a degree of cold that would prove fatal to the majority of those left to take their chance; of course, sorts that are in ordinary years fit for cutting from November to January are best left standing erect, as laying would retard their earliness. We usually cut such sorts as Veitch's Autumn Giant Cauliflower, Veitch's Winter Broccoli, and Snow's Winter White as

they come fit for use, breaking the leaves down over the heart to still further protect from early frosts, and any not required for immediate use are lifted with good balls of earth and planted in pits. By this means it is quite possible to get a continuous supply of either Cauliflowers or Broccoli. Sorts for early winter use that are intermediate between the two will yield a long succession for cutting if sown and transplanted at different dates in quantities proportionate to the demand. Snow's Winter White, if true, is a first-rate sort, as is also Veitch's Winter Broccoli; they are both extremely self-protecting, the heart being enveloped in several layers of leaves, that curl over and answer the double purpose of blanching and protecting the heart. We plant these sorts largely for winter use, and the Early Penzance or Cornish Broccoli for an early spring supply, and a large quantity of the latest sorts, such as Model, Leamington, Cattell's Eclipse, and Carter's Champion. Of these we had good examples this year in June, and they are most acceptable in seasons that almost defy the production of very early crops out-of-doors; therefore, extra late productions are doubly valuable. J. GROOM.

DISEASE-RESISTING POTATOES.

THE claim put forth for Magnum Bonum Potato, is not that it is disease "proof" but that it is disease "resisting"; a very different thing. During the past season it has had to undergo a severe test, and it has withstood it well. In my neighbourhood it has been grown in several localities by market growers, and the proportion of diseased tubers found is so small that it is barely worthy of mention. One grower states that he had but half-a-peck diseased in eighteen bushels, and others report of none at all diseased. This is a remarkable fact, to hear of any Potato this season, and contrasts strikingly with Regents and Victorias, which have diseased badly. The same grower said that "Regents and Victorias will cause me this year to lose £200; in fact, enough to break my back;" and but for the Magnum Bonums and Champions—which latter last year were fetching nothing in the market, and are now making from £8 to £9 per ton—he might have been ruined. I am confident that next year the market growers will grow six times more of Magnum Bonum than of any other kind.

"J. S. W." makes a reference to some correspondence which has appeared in the *Standard*, and quotes a remark that the system of "natural propagation by crossing the best and strongest growing varieties" has already brought us one disease-resisting Potato. There is not much novelty in that, observation, and it was probably only written by an amateur correspondent. We have been producing new sorts by means of crossing naturally and artificially for the past thirty years, but the results, so far as the production of disease-proof kinds are concerned, have not been encouraging. It is remarkable that the most successful example in this direction ever raised should have been not the result of artificially crossing with the intention of producing a disease-resisting kind, but simply the result of an accident; but how accomplished, the raiser still remains in ignorance. Mr. Clarke, of Christ Church, with whom it originated, says that he found, during the hot summer of 1870, three small seed-balls attached to a plant of the Early Rose (a Potato that was hardly likely to have been selected for this special purpose by a hybridist), and that the flowers from which these were produced had been naturally fertilised by some other kind is evident. From the fact that in this country American sorts never set their blooms, and are never fertilised except by the aid of foreign pollen, as they are devoid of it, I am inclined to believe that Paterson's Victoria was the pollen-parent, but it is nevertheless only conjecture. I cannot agree with "J. S. W." in his estimate of Magnum Bonum, that what disease-resisting properties it possesses are due to its lateness in ripening. Victoria, for instance, is as late, and yet it diseases badly; and the same may be said of many others. With me the foliage of the Magnum Bonum died long before the tubers were ripe, but I have not a diseased one. Some believe that it is to the hard woody nature of its stalk that Magnum Bonum owes its disease-resisting powers. This is no doubt the truth, and to that feature, and not to its lateness, does it owe the good qualities it now possesses. A. D.

A Peril near Home.—Lately grave cases of poisoning by supposed Mushrooms gathered in Hyde Park and Regent's Park have fallen under treatment at Middlesex hospital. The symptoms were urgent and included violent delirium, though happily the patients recovered under treatment. This is a matter of general interest, because it is quite possible that some of the Mushrooms supplied by costermongers, and even family greengrocers, may be obtained from the same localities; and it is by no means so easy as is generally supposed to distinguish the genuine edible from the poisonous fungi. The public should be warned.—*Lancet*.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Ne Plus Ultra Pea.—Amongst late kinds I do not find any to equal this well known sort, either for colour, flavour, or productiveness. It has also a most continuous mode of bearing and continues growing and flowering until checked by the early frosts. When cooked it retains its deep green colour admirably, and, as regards flavour, it is simply as good as one can expect to ever get Peas. Every one is anxious to obtain the earliest Peas in cultivation, but probably the latest are equally useful to most cultivators, and if asked for the very best late kind, I should certainly still hold to *Ne Plus Ultra*.—J. GROOM, *Linton*.

Potato Beauty of Hebron.—I have grown this Potato this season, and find that it has withstood the disease better than any other sort I have grown (except *Magnum Bonum*)—in all fourteen sorts. From 14 lb. of seed I dug about 6 pecks of fair-sized Potatoes and found only three diseased tubers. As regards quality when cooked they are first-rate. Although not so white as *Snowflake*, they are equal to it as regards mealiness. I intend to plant more of this sort next year.—J. T., *Avalton*.

Tender and True Cucumber.—We have grown this Cucumber for the first time this season, and find it to be one of the very best we ever grew. It is not only a handsome Cucumber both in length and shape, but it is also a very free bearer. Ours have been grown in ordinary manure pits with a flow and return pipe for top-heat when required. From under ten lights we have cut a great quantity of Cucumbers; I counted forty fit to cut to-day. Those who have not already tried this variety will, I feel sure, not regret doing so.—H. J. C.

Sutton's Magnum Bonum Potato.—In travelling through various parts of Wales and Ireland I heard an excellent account of this Potato. It was stated to be the only variety that resisted the disease with any success, and which, notwithstanding the peculiarly bad season, gave an excellent crop.—V.

Webb's Summerhill Cabbage Lettuce.—This is a large yet delicate Lettuce; its heart is close and white, crisp and sweet, being well protected by the outer leaves; altogether it is an excellent Cabbage Lettuce.—H.

THE FRUIT GARDEN.

CAUSES OF FAILURE IN STRAWBERRY FORCING.

A STRAWBERRY plant which, when placed in heat, starts feebly into growth, seldom realises in the succeeding phases of its growth the expectations of the cultivator. The vigour and freedom with which the first leaf is made fully indicates the future progress of the plant. This being the case, it is evident that every precaution ought to be taken to ensure an unchecked and healthy growth in the first stage of forcing, and many of the failures that occur may be attributed to the want of observance of this important matter. I am fully convinced that in many cases an insufficiency of nourishment and moisture in the autumn would account for lack of vigour in the spring. It is highly important that a sufficient number of old leaves should remain on the plant to ensure a free root action when placed in heat, and unless these are healthy and of good substance they cannot efficiently perform their functions. Healthy foliage can never be secured if the plants do not obtain a constant supply of nourishment. When the pots towards the summer become full of roots they should be either top-dressed or the plants kept growing by means of liberal supplies of manure water. Soot is a capital manure for the latter end of the season. It does not stimulate so much as other manurial agents, but it imparts a substance and colour to the plants which they never appear to lose. It is sometimes recommended that water should be sparingly administered during the last stage of growth. I never could understand the principle of such treatment, my own experience having always tended to prove that want of moisture at the root at the period when the crown is maturing is extremely injurious. A feeble growth, weakly trusses, and often blindness might be traced to neglected watering. Not only should the plants never remain dry, but they need frequent saturations. These remarks only apply to well-rooted plants: when the pot is not well filled with fibre there is but a slight chance of a good crop. The parts containing the germs of the flowers are formed in the autumn. The more healthy and free the plant the stronger will be the germ, and the vigour of the flower truss will thus be found to depend upon the state of the roots, and the robustness of the plant. If the necessary conditions in the autumn are not fulfilled the germs are not formed; if also the root action in the spring is sluggish and impaired the plants will prove sterile, and develop foliage instead of flowers.

Another source of mischief is the indiscriminate use of the syringe during the starting period, and many cases of unfruitfulness may be traced to the daily sprinklings which many consider indispensable. If the crown of a Strawberry plant is dissected the future flower truss will be found in the form of a minute speck not so large as a pin's head." If by any chance water finds its way amongst the leafy folds which envelop the germ and remains there, the germ will turn black, rot, and the fruit prospect destroyed. This injury is not perceived until considerable progress in growth is made, when the grower finds to his surprise that he has leaves instead of fruit. In fine bright weather a slight sprinkling is beneficial, but evaporation being very sluggish syringing should not be practised if not needful, for unless carefully applied it is liable to cause irreparable damage. The development of the flower truss is very interesting, and should be observed by all who are inexperienced in Strawberry forcing. When the plant is first started a small whitish point alone indicates fertility; as the leaves push up this little speck develops gradually, expanding and dividing itself into other minute points, which represent the individual flowers. By the time the third leaf appears the flower truss is ready to issue from the crown. By this is seen how important it is to guard against a hurrying foreign temperature during this period of growth. The first month is undoubtedly the most critical time, and too much heat then will have the effect of starting the plants rapidly into growth, but the flower truss will be left undeveloped. The best and strongest plants obtainable may be rendered sterile by the injudicious application of heat and moisture at the time of starting. Dryness at the root during the winter is also an often unsuspected cause of unfruitfulness. Plants may get dry, but they should never remain so long at a time. If the foliage once shows signs of shrivelling the vigour of the plant is impaired, and a weakly flower truss or perhaps none will often be the result. These are some of the causes of failure, all of which may be easily avoided. Sterile plants are a source of vexation to the grower, and the uninitiated are often at a loss to account for the absence of the flower truss when the plants are to all appearance in good health. A well grown and properly nourished Strawberry plant will seldom prove unfruitful if fairly and gently treated in the earlier stages of forcing.

Byfleet.

JOHN CORNHILL.

THE CURL IN PEACH TREES.

At p. 278 it is asserted that the "curl" in Peach tree leaves "is caused by an internal fungus," &c. So far as any practical suggestions for curing the evil is concerned, gardeners are correct in attributing the disease to cold or unfavourable conditions of weather, and whether it be fungi or not they will undertake to cure it by protection. Fungi may be the immediate cause, or just as likely curl may be the cause of the fungi, but at least it is certain that the former appears under adverse conditions of climate and weather only, and never in glass houses that are managed with ordinary care. Why do not fungologists suggest a cure? Gardeners say it is cold or bad weather that produces curl and they can cure it by protecting the trees from the supposed cause. Let fungologists practise their theory and arrest the fungus outdoors when it once begins, or even prevent its appearing. That the cause which can be dealt with most readily and successfully is the true one will, I think, be generally admitted, and the only one worth caring about from a practical point of view. I have as much respect for scientific teaching as any one, but to be told every now and then, as we have been in the case of Peach blight, that we are ignorant of the cause and slow to apprehend, while as yet gardeners only have been able to suggest a cause which by prevention they can cure it is, to say the least, amusing. I have seen curl disappear completely in a single season from trees after they had been covered with a glass roof, and continue to be as bad as ever on the trees that were not covered up to the door of the house. What gardener would take the trouble to look for the cause of the curl through a powerful magnifying glass when he can observe its progress without it on a larger scale, and study it with greater prospects of success? What happens in a case of curl is this, as most gardeners will testify: under the influence of a spell of genial weather the trees start into growth, and do well enough till a change comes, with probably a cold or east wind, which lasts for two or three weeks as it often does. The growth of the trees is at once arrested, and soon after the curl appears, and it continues to extend and keep pace with the slow growth till more favourable and genial growing weather returns, when the points of the affected shoots push out rapidly into new growth and leave the curl behind them and quite escape from it, the worst results being that the growth is thrown back and the later growth is imperfectly matured. Fungologists attributed the Potato curl to a fungus as well, and those who did not know what it really was, and had never seen, or, at least, noticed it before, actually described it from a laboratory investigation as a new disease at the

time; but who ever saw it occur except under the influence of ungenial weather? I do not deny that other causes than cold may accelerate the disease in the case of the Peach, such as cold or undrained borders, or anything that hinders healthy development, but when it becomes general, as it has been during the past exceptionally cold summer, only one cause can be assigned for it, that is, the weather. C.

PEACH CULTURE AT FLOORS CASTLE.

MR. KNIGHT, the able superintendent of the gardens at Floors, has stepped out of the beaten path in the management of Peach trees under glass, and the result is so satisfactory that a few lines may not be uninteresting, particularly to those who have limited space for making borders. In days gone by it was thought necessary to have outside borders equivalent in width to the breadth of trellis to be covered, but at Floors the roots are confined to narrow raised pits, 2 ft. 6 in. in width, and about the same height above the ground line—in reality an extension of the pot system. Nine years ago a span-roofed house, 90 ft. in length and 12 ft. in width, was in use as a plant stove. A glass partition divides it across the centre; the narrow pit runs along the south side, and rises to within 12 in. of the bottom of the trellis. In the centre of the first compartment, 45 ft. in length, a mound of compost was placed and a dwarf maiden Hunt's Tawney Nectarine—an early variety, worthy of general cultivation—was planted. In the second compartment an Early Grosse Mignonne Peach received similar treatment, the compost used being pure loam and lime rubble.

The trees, trained upon the extension principle, seem to have made equal progress, which must have been as rapid as it is satisfactory, the vigorous short stems presenting the appearance of twenty years' growth, and the trellis in each house, 45 ft. by 12 ft., being evenly and entirely filled with bright short-jointed shoots bristling with blossom-buds of the most promising character. I did not ascertain from Mr. Knight the number of fruit he took from each of these young giants; but judging from the way in which he taxes the trees in his late houses, I conclude that he takes at least one fruit from every square foot of trellis. Advocates of the extension principle of training know that roots increase as rapidly as leaves and wood, particularly when they are placed in comfortable internal beds, in which, as in this case, thousands of healthy feeders rise to the surface ready to devour the good things provided for them through the growing season. Clean healthy trees must be formed before they require feeding, and here Mr. Knight has displayed his skill by selecting maiden trees that have never been shortened back, by keeping his knife in the sheath and by the timely removal of all surplus shoots with the finger and thumb.

In many gardens, particularly in low cold situations, we make our Peach borders wider and deeper than is necessary for the training space allotted to the branches; young trees grow vigorously and soon require more space, but anxious to retain a certain number we resort to shortening back, thinning and root-pruning, the only effectual remedy. Mr. Knight has avoided these necessary evils by giving his branches full play, and by making his narrow internal borders piecemeal, and as often as the numerous fibres require fresh supplies of the firm resisting calcareous food in which all stone fruits revel without becoming gross.—W. COLEMAN, in *Gardeners' Chronicle*.

ROOT PRUNING.

I THINK Mr. Groom (p. 316) rather exaggerates the difficulties and disadvantages of root pruning. Perhaps his experience in this matter is confined to the favoured climate of the south of Kent, where it is well known that Apples and Pears, &c., are grown successfully with as little skill and attention as anywhere in the kingdom. I have not so much knowledge of Kent as Mr. Groom has, but from what I have seen of the orchards there it appeared to me that the system of pruning and training adopted generally was of rather a loose description. To write from Kent on the subject of root pruning and say that it is not only useless, but injurious in the majority of cases, may hold good, but in late and wet districts in the north of England and other cold localities the theory would be found impracticable. I have been one of the first and the last to advocate the extension system of training fruit trees, that is, of planting and leaving them undisturbed, except thinning the branches when needful. I know that there are conditions which can only be dealt with by root pruning, and Mr. Groom will not readily convince gardeners to the contrary. He states that in his neighbourhood "root pruning is unknown; that worthless or worn-out trees that are not vigorous enough to graft being grubbed up and burned." Could there be any alternative in such a case? To think of restoring lost vigour in old trees by root pruning is altogether a fallacy. Another "impression"

of Mr. Groom's is that "fruit trees of all kinds" are induced to make gross wood by being starved, and he suggests that the roots should be prevented from going down into an ungenial subsoil by applying rich dressings to the surface of the border. There are Pear trees against a wall here which have been partially lifted twice in fifteen years, and encouraged to stay near the surface by annual rich dressings, but it does not prevent them penetrating deeply. There are many feet of strong clayey loam underneath, and thus the roots will penetrate as soon as they are let alone, and the result being an annual growth of great length, and vigour, and barrenness, except perhaps at the very extremity of the branches. We cannot root prune as often as we would like. In another part of the garden here we have a great number of finely grown pyramidal Pears and Apples, and the crops they bear in this climate are in exact proportion to the amount of root pruning we can do periodically. Though lifted quite out of the ground a few years ago, many of them would now make shoots 5 ft. long if allowed. Another remarkable fact about many of these trees is that they are not growing in a deep soil, though a tolerably rich one; nor is their over-luxuriance due in any ease to the roots getting down into the subsoil, but simply to a cool soil and climate, which we cannot counteract except by root pruning, and thereby checking the root supplies. I quite agree with Mr. Groom that it is needless "taking up any kind of tree to examine its roots." No one would do so where the necessity of root pruning was so plainly indicated by the gross habit and barren branches. Where these are found, particularly in the case of wall and trained trees generally, there is only one cure, and that is "root pruning."

J. S. W.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Dell's Hybrid Melon.—Except for trial I have grown nothing else but Colston Basset Melon ever since it made its appearance, having found it a good constitutional variety, a free bearer, and the fruit excellent in flavour in good and bad seasons. In future, however, I intend making an exception in favour of Dell's Hybrid, which promises to have all the good qualities of the Colston Basset, while it is considerably larger, more juicy, and of better flavour; which is saying a deal in its favour, as there are few Melons so sweet and good as the Colston Basset variety. There is, or was lately, to be seen a house about 100 ft. long at Drumlannig Castle Gardens devoted entirely to this Melon, all the plants carrying fine fruit—some single fruits weighing 5 lb., and the flavour excellent, and though the season has been dull and wet, and the house in question glazed with obscure glass, Mr. Thompson speaks very highly of it indeed. By the way, how is it that Melons thrive so well in dull seasons like the present, and so often grow badly in fine seasons? In 1868, which, as will be remembered, was unusually hot and dry from May till October, we had much difficulty with our Melons, and the inferiority of the crops was noticed by others at the time; while in 1872, which was a wet season—when we registered about 70 in. of rain here—our crop was an exceptionally fine one. This season it has been the same. We have had more fruit than we could use from the beginning of the season until now, and, moreover, never were better as regards flavour and sweetness. I only state the fact, but I attribute such results to the better preservation of the foliage. In hot dry seasons the leaves are apt to be attacked by insects, and otherwise suffer from the continued sunshine when transmitted through 21-oz. glass, and are unable to perform their functions properly till the end. It may be different in the open air, but I have often thought that plants are less able to stand a high sunheat under glass than when quite fully exposed—the temperature being equal in both cases.—J. S. W.

Apples for Market.—The present season has been remarkable as regards the fluctuations in the market prices of fruits, and more especially the common orchard kinds, for although a light crop generally, some kinds are much below the average, while others have produced a crop double that of ordinary years. The most notable being Apples, that are at the present time selling wholesale at from 8s. to 10s. a sieve; this is an extraordinary price, for if large kitchen Apples are worth 1d. each in the market, they cannot be retailed at anything like a reasonable price; about here moderate sized trees of Stone's Apple have realised £2 or £3 per tree. On the other hand Pears and Plums are below the price of some seasons when fruit is much more abundant, and decidedly below the average as regards quality, still it seems singular that Pears and Plums are only worth about half the price of Apples that are equally below the average in point of quality. I have no doubt that this will give an impetus to Apple planters to depend even more largely than ever on the king of hardy fruits, and that Apples will to a great extent supplant Pears as standard trees. I find here that even the largest growers are gradually reducing the number of sorts, and making a selection rather than a collection of varieties is the plan now adopted.

The very early or very late sorts are those most sought after, as they always sell well, while the mid-season kinds are those that glut the market, and bring prices down below a remunerative point. At present fruit culture for market is only in its infancy, but promises to assume larger proportions.—J. GROOM.

A New Raspberry.—A Raspberry that we have before noticed in THE GARDEN is thus alluded to by Professor Sargent in the *American Agriculturist*: "We have cultivated for the last two or three years a *Rubus*, a native of Manchuria, Northern China and Japan (*Rubus crataegifolius*, Bunge), with the supposition that it was a Blackberry, and of little horticultural importance or value, except as an ornamental plant of neat habit, remarkable for its rich autumnal colouring. This year the plants have fruited, and it proves to be a true Raspberry. The fruit is large, firm, clustered, nearly semi-spherical, of a brilliant orange-scarlet colour and with a flavour which suggests the common Black Raspberry or Thimbleberry. The largest fruit I have noticed is $\frac{3}{4}$ in. in diameter, and rather more in length. Probably as a table fruit the Chinese Raspberry is hardly worth cultivating, but it is suggested that by using it to cross with some of the delicate garden varieties, a hybrid might be obtained hardier than anything now in cultivation. Such a hybrid might be expected to produce large, high-coloured, and handsome fruit of great substance, and therefore valuable for market purposes. The neat habit, great hardiness, large brilliant fruit, and especially the rich claret colour which its foliage assumes in autumn, render the Chinese Raspberry one of the most desirable of the many shrubs recently introduced from its native countries."

Cleaning and Painting Vines and Peach Trees.—As the time is now coming on when gardeners will be cleaning and painting their Vines, may I ask some of those who have been in the constant habit of going over all their Vines and Peaches with the brush and the scraper, with the object of checking red spider and thrips, &c., to try the experiment of leaving some of their trees undressed? For my own part, I do not believe that scraping all the loose bark off Vines and painting them afterwards does the least good, but is the cause of much useless labour. I make an exception in the case of mealy bug on Vines, but I apprehend gardeners are, as a rule, too careful to let that pest ever get upon them. I have never either cleaned or painted a Vine here, and I will undertake to say that our houses are as free from insects as those of any of our neighbours, and may be cleaner than a good many; at least, I could show Vines at the present time with leaves green and healthy though the crop was cut a good while since, and the wood quite hard and ripe, and early Vines carrying their foliage healthy till it fades in the natural way are the best test. In passing through these Vineries the other day a gardener from the south said the Vines reminded him of the famous Vines at Berkhamsted, which he said were never either peeled or painted. I make these remarks under the conviction that many gardeners would be glad to dispense with the labour of cleaning their Vines if they thought they could do so with safety.—J. S. W.

Transplanting Large Peach Trees.—Scarcely any fruit trees move with so little check as the Peach. It is no uncommon occurrence to build a Peach-house in autumn, stock it with full-sized trees immediately, and take a good crop of fruit the next year. What a great saving of time is thus effected! If young trees are planted it is three or four years before such results can be obtained, if they thrive ever so well. Trees from six to ten years old move the best; in fact, if such trees are moved carefully from one part of the garden to another, they suffer no check at all if the operation be carried out in the autumn. I have moved trees in February and took a crop in a cold house the same year, but it is best to transplant them in autumn, even where no forcing is done. One of the advantages of moving trees of from six to eight years old is that their branches are then more flexible, and will yield to the trellis more easily; and this is a consideration, as very few wall trees can be made to fit exactly to a trellis in a house, if they have more than eight or ten years' growth.—E. H.

Utilising Unripe Grapes.—This unkindly year many Grapes in cold houses will not ripen; a good use for them will be found in the following receipt, which we learnt from a cook who had been stationed at Malta, where Grapes are plentiful:—To stew Grapes, pick them off the stalks, put in a jar with a little water and some white sugar, put in the oven for about half-an-hour, serve in a glass dish. This makes a pretty dish, and even with red Grapes is not at all bad.—GEORGE F. WILSON, *Heatherbank, Weybridge*.

Gridiron Pear Trees.—We noticed a wall beautifully covered from top to bottom with these at Bodorgan. They were only planted in the spring of 1872. "Gridiron" is Mr. Ellam's name for them, and a very good one it is. Walls can easily be covered in this way in three or four years, whereas, by the old horizontal plan, a very long time was frequently wasted in covering them.

PLATE CCI.

TEA ROSES.

Drawn by ALFRED PARSONS.

CHARMING as all Roses are, there are none more beautiful than the Teas, and of these two of the most charming are represented in our plate this week. *Souvenir d'Elise Varden*, the elder of the two lovely sisters, is indeed, when well grown, a perfect Rose. Unfortunately, its habit is not very vigorous, as, in my experience, it does not ripen its wood well, and is consequently very liable to injury from the winter frosts. It grows best on dwarf standards, and should be planted in a sheltered situation. I have never seen this Rose better grown than by an amateur whose plants were under the protection of a dwarf wall built expressly for them; they were half standards, not trained against the wall, but planted some 2 ft. from it, and the blooms they produced certainly well repaid him for the trouble he took in their culture. Of *Marie Van Houtte* how can any one adequately describe the beauty? If only allowed to grow one Tea Rose I should unhesitatingly choose this one, perhaps because of all Teas it is to me the most kind, seeming to find in my garden a soil that suits it well. Anything more lovely than the delicate rose tinting of the outer edge of the petals I cannot conceive; it seems as if it were blushing at the perfection of its own loveliness. This Rose was sent out by Ducher in 1871. Its habit is very good. I have several plants of it on the seedling Brier, which have grown to the top of a wall 10 ft. high, and on them may frequently be seen forty or fifty good blooms open at the same time. It is one of the earliest spring Roses, as well as one of the latest autumnal bloomers, and I have on more than one occasion cut a bloom of it from a south wall on Christmas Day. The seedling Brier seems to be the most suitable stock for this Rose, and if the plants are frequently syringed, and the roots well supplied with liquid manure, the growth it makes is very vigorous. I am inclined to think that the generally accepted theory about not pruning Tea Roses much is wrong, and that they do better when cut moderately hard in the spring. They should be protected during winter by bracken placed amongst their shoots, and their roots should be well covered with litter.

Heavtree.

R. N. G. BAKER.

Dwarf Silvery Grass.—The remarks of Mr. T. Williams (p. 303) respecting *Aira caryophylla* are evidently wrong. I infer from the description he gives that he means one of the glaucous varieties of Fescue Grass, either *Festuca glauca* or *F. punctata*, which answer well for the purpose he speaks of. *A. caryophylla* is one of our diminutive annual native Grasses, which grow in sandy soils. It makes its appearance in March or April and flowers in June, and soon after disappears. Its foliage is at all times scanty, and in bloom it is scarcely distinguishable from *Agrostis nebulosa*, which is so much used in bouquet making.—C. M.

—Mr. Thomas Williams, Ormskirk, the writer of the note on the dwarf silvery Grass for the flower garden (p. 303), intimates to us that he inadvertently called it *Aira caryophylla*, whereas it should have been named *Festuca glauca*.

An Ancient Seed Shop.—The *Standard* of Sept. 27, in its report of the recent excavations at Pompeii thus speaks of the discoveries that were made: "As it was impossible to be at all the points of interest, ten new excavations being carried on simultaneously, I went, being advised by those most competent to judge, to section No. 9, and there, in a small division parallel to that already numbered five, the curiosity of the spectators was soon richly rewarded. Almost with the first strokes of pick and spade, used, by the way, as only Pompeian diggers know how, there came to light a quantity of household objects, chiefly of those light and beautiful forms and delicate workmanship to be found in even the humble Pompeian dwellings. A detailed list of the various articles in the order in which they were found fills six closely-written pages in my notebook. There were bronze amphora lamps, brooches, bracelets, delicate vases, and one very large and elegant bronze candlestick, earthen vessels of various forms, fragments of glass, amongst which were the pieces of a lovely little glass vase of the most brilliant blue colour. The belongings of the upper and under stories of this little house were curiously mingled together, objects of mere ornament being mixed up with kitchen utensils. Then came some large tiles and fragments of a large beam of wood, showing that the roof had been crushed in on the lower stories. It is judged to have been the shop of a seedsman, for besides some bronze scales and weights, several large heaps of small Beans, grain, and Hemp seed came to light, with portions of wooden casks, and canvas sacks in which they had been kept. One piece of sacking which I had in my hand still tied with a bit of string was wonderfully perfect although quite black."

TWO TEA ROSES

1. SOUVENIR D'ELISE VARDEN 2. MARIE VAN HOUTTE

GARDENING FOR THE WEEK.

Greenhouse.

Clianthus Dampieri.—Where this gorgeous greenhouse plant is grown it is best when raised from seed, and, managed as a biennial, the only difficulty with it and that which has caused many to cease growing it, is that its roots cannot withstand being disturbed by frequent potting in the way that most plants can. It should be treated on the "one-shift" system, with not the slightest disturbance of its tender rootlets, even so far as moving the drainage material in potting. Plants that were sown in the spring and are now in small pots, even if suffering for want of root-space, will, in most cases, be better if allowed to remain as they are until after the turn of the days. To grow this *Clianthus* strong and well requires a good deal of room, and to place the plants now in pots large enough to admit of their attaining the desired size would necessitate the use of a larger quantity of soil than the roots would take possession of so soon as desirable during the comparatively dormant winter season. With young plants in such a condition as those above mentioned, it is advisable to use a little weak stimulant in a liquid state from time to time.

Mignonette for Winter and Spring Flowering.—

Where the cultivation of *Mignonette* is made an especial feature, the plants raised from seed early enough to give time for their attaining a good size should now be accommodated with a good position in a light pit or house and placed close to the glass, so that they can receive plenty of air, for on this, in a great measure, depends their leaves having sufficient strength and substance to keep green and healthy during the winter, a character which adds so much not only to their appearance, but to the quantity of good flowers the plants are able to produce. Where this favourite sweet-scented plant is required almost throughout all the year, it is necessary to keep up a succession of sowings; the plants sown later in the summer, and again about the beginning of September, will need to be kept quite cool. A light, airy pit or cold frame with the lights drawn completely off on fine days is the best position for this late stock, as the object is not to bring them on quickly, but rather to keep them short and sturdy until the winter is far advanced, when, through the increased light they will naturally make more growth, and come into flower and last until the spring-sown plants are ready to succeed them. One essential in the pot culture of *Mignonette* is to keep the plants scrupulously clean from aphides that establish themselves on the undersides of the leaves, and if not sought for, they frequently, before being noticed, weaken the foliage so as to cause its premature decay. Diluted manure water should be given every week to the most advanced plants.

Schizanthus.—Though somewhat common plants, there are few amongst the many more pretentious subjects that can be made to produce a better display in the conservatory or greenhouse during the spring when well managed. If liberally treated they will attain a size seldom seen amongst the generally crowded examples grown out-of-doors. The quantity of flowers they will produce will of course be proportionate to the size of the plants, which will be best regulated by the size of the structures they are required to embellish. To grow them to a large size, the pots will need to be 12 in. or 13 in. in diameter, and any plants that are suffering for want of room may be at once transferred to pots this size; for if allowed to remain long in the small-sized pots after the roots get crowded, the repotting later on will have little effect in benefiting the plants. The soil should be such as is calculated to grow *Pelargoniums* well—containing a good quantity of manure. Similar treatment in other respects to that advised for *Mignonette* will answer for these also.

Pelargoniums.—Plants of the large-flowered kinds that were kept on blooming beyond their usual time, and were cut down late, will have broken sufficiently to admit of the old soil being removed and the plants repotted, potting them, as in the case of those previously cut down, in smaller pots, in which they can remain until after Christmas. These plants will last for a number of years, and by treating them in the manner advised the earliest portion will come into flower sooner in the spring, and the latest will acquire the habit of regularly flowering late, by which they meet the requirements of those who grow them for general decorative purposes, and whose object is to keep up a display over as long a period as possible. The first and second potted plants will now have begun to root freely, and may receive a little more water, but care must be taken from now and throughout the winter months that the soil is only kept in a sort of half-moistened condition, that is, much drier than the majority of other plants would be kept. It is necessary to impress this upon those who have not had much experience with this section of *Pelargoniums*; for if the soil be kept as moist during the winter as most other plants in a growing state would need, the result is, that the

roots make little or no progress whatever, and the shoots that are made would be long-jointed and weak, which would produce leaves so deficient in substance that they would turn yellow and prematurely die away, leaving the plants when the flowering season arrives thin and naked at the bottom. Those first potted should, as soon as they require it, have a few sticks put to them, so as to admit of the shoots being tied out in a way that will keep the centres of the plants open; for, though it would be a mistake to train plants required only for ordinary decorative purposes to the extent necessary for those that have to be moved about for exhibition, still to grow *Pelargoniums* in a way that will preserve their natural habit, the plants must be kept sufficiently open to preserve a sturdy habit.

Fuchsias.—Plants that were struck at the end of July and afterwards placed in small pots should not be allowed to remain in these too long, for if once they get into a stunted condition they will never grow freely afterwards. They should now be placed in 5-in. or 6-in. pots, which will be large enough for the winter, potting them in good loam, well enriched with rotten manure, with the addition of enough sand to make the whole sufficiently porous, but not too light. They should, if possible, be kept on a shelf close to the roof in an intermediate temperature. Tobacco smoke is injurious to the leaves of young *Fuchsias* such as these, especially during autumn and winter; but if aphides make their appearance, the plants should be dipped in Tobacco water. These young plants will make much better specimens than old plants; but where provision has not been made by striking them at the time these were put in there is no alternative but to use the old plants again next year, for which purpose those that flowered first during the past spring should now be put to rest. *Fuchsias* will bear a great deal of hard usage, and they are too often subjected to such indifferent treatment as to deprive them of the possibility of attaining the well-furnished and vigorous condition they are capable of. A very frequent course is to keep on with the same old stools year after year, and in the autumn, when they have become shabby by losing their leaves, they are at once thrust under plant stages, into sheds, or any dark out-of-the-way corner, and there allowed to remain with the soil surrounding their roots as dry as tinder, which destroys the greater portion of the fibres, thus preventing them from breaking in spring in a manner that will ensure healthy growth. I have found it much better to take those that flowered earliest in the spring and from the present time to gradually reduce the quantity of water applied to them until there is but little further disposition to grow, and then to cut the side branches close in, and reduce their height so far as is considered necessary. The plants should be placed as closely as possible in any house or pit where they will be secure from frost, and merely giving them water enough to cause the buds to break, but not more than will maintain them in a half dormant condition until after the turn of the days. Plants that were treated so as to bloom late throughout the autumn, if well furnished with advancing buds, as they should be, will keep on flowering for some weeks, and though the display they make is not equal to that produced earlier, yet when flowers are scarce they will be found useful.

Bulbs.—It is now quite time to see about potting the general collection of such bulbs as are required for winter and spring flowering, especially *Hyacinths*, which, in common with all other plants of a similar nature, evince by their roots beginning to develop that they want to be placed in soil. It frequently happens that the indifferent way in which *Hyacinths* and other bulbs flower is attributed to some deficiency in the strength or maturity of the bulbs, when in reality their unsatisfactory blooming is caused by the first efforts of the bulbs to develop roots taking place before they are put into soil, by which neglect the tender fibres are injured. In the growth of these plants, and particularly *Hyacinths*, there is no necessity for using pots so large as are often employed. I have frequently tried the deep unsightly pots that are made purposely for the cultivation of *Hyacinths*, but I never found the flowers improved in the least thereby. The splendid spikes which the London market growers produce with two or three bulbs put in a small pot only just sufficient to admit them, is sufficient evidence that a great deal more depends upon the condition and strength the roots have acquired previous to the time of their being forced, than on any assistance that can be derived from a large amount of root space. In selecting *Hyacinths* I should advise amateurs to rely upon the good and well proved older varieties, for, although they are offered at prices very much below that of the comparatively new and scarce kinds, the difference in price is far from an indication of a proportionate, or often any, superiority in the flower. Though *Hyacinths* are such general favourites, their comparative uselessness after the first season's blooming makes them much dearer than most other bulbs. The *Polyanthus Narcissi* have not this objection, for after being flowered in pots they can be planted out in the open borders where they will make a fine display in succeeding years; the agreeable perfume and form

of their flowers especially adapts them for ent purposes. Similarly in subsequent seasons Tulips flower well, and many of the fine single-flowered varieties deserve to be much more largely grown in pots than they are. Crocuses, especially such kinds as Queen Victoria (white), Sir Walter Scott (pencilled lilac), Pride of Albion (white, striped violet), Mont Blanc (white), and New Golden Yellow, are very beautiful, and most useful where grown in sufficient quantities so as to keep up a succession. If their wants are attended to after blooming they will, in future years, be equally as effective out-of-doors, and much superior to the commoner kinds more generally used for planting in borders. Scillas, particularly *S. sibirica*, can hardly be too largely grown in pots, in which there is no difficulty in getting them to bloom freely. The charming shade of blue and elegant manner in which the flowers are produced especially adapts them for bouquets. When grown in sufficient quantities they will be found most serviceable, particularly in severe winters, for a continuous supply until those in the open borders flower; ordinary sandy loam suits all the above kinds of bulbs admirably, and the pots should be well drained. As to treatment after potting I have found nothing that answers the essential object of getting a plentiful supply of roots before much top-growth is made, better than the old-fashioned method of plunging them in a bed of coal ashes out-of-doors with 4 in. or 5 in. of the same material underneath the pots in order to keep out worms, and 6 in. above. In five or six weeks they will generally have made plenty of roots.

Ixias and Sparaxis.—These beautiful plants are fine objects in pots, their rich and varied colours, together with the graceful habit of their flower-spikes, are such that no doubt they would be much more cultivated in this way if they were better known, though most of them are old introductions. Six-inch pots are large enough for half-a-dozen bulbs of these; but after potting they should be placed in a cold frame, so as not to be so much exposed to the wet in the way that Hyacinths and other similar bulbs would be, as they do not like as much moisture until they have got plenty of roots.

Tritonias.—These are amongst the most useful greenhouse decorative subjects we have, as they may be had in bloom from early in the season until the summer is far advanced, when greenhouse flowering plants are comparatively scarce; but though thus not coming under the head of forced flowers, it is well for those who think of growing them to obtain them at once and pot them. Those who are acquainted with the old well-known orange kind (*T. crocata*) may form some idea of the effect that may be produced by growing an assortment of the lush, scarlet, white, and shaded varieties. A dozen bulbs grown together in 7-in. or 8-in. pots will be found a very useful size; where larger specimens are needed, all that is requisite is to have larger pots containing a proportionately larger number of bulbs.

Potting Soils.—The continued wet throughout the late summer has not permitted either turfy loam or peat getting so dry as desirable before it has been stacked. At one time it was the practice with plant growers to keep potting soils much longer before being used than has since been found advisable. As it has been proved that the retention of the fibrous matter which the soil contains is a matter of the first importance to the healthy development of the roots of the plants to be grown in it, it is evidently a mistake to keep potting soil so long before it is used, as it causes the fibrous vegetable matter to become more decomposed than necessary. If sufficient time has elapsed for the roots of the Grasses, Ferns, &c., which the loam and peat contain to die and part with their moisture, they are in the best condition for use. With this view a supply that will last for one year is enough to lay in at a time. In stacking loam for potting it is the custom with some to mix as much manure—usually stable manure—as will be needed, but where this is mixed with the soil at this time it should be quite fresh, as, if rotten material be added it is sure to contain quantities of worms, which do much mischief to the soil, and whatever proportion of manure is required for the plants ultimately to be potted can be added at the time of potting, using it in a dry state so as not to admit of there being worms in it. Leaf-mould prepared for use next spring should be such as afforded by the leaves that fell last autumn, as this also if too old gets into a close adhesive state and loses the fibre, the presence of which is quite as much benefit to the plants as are the food elements which the material contains. Enough Sphagnum Moss for the year should now be got, as like other vegetable matter it is at this time in its best matured condition, a state that enables it to resist decomposition longer. It is also better to secure it before winter, as with severe frost it sometimes gets so far injured as to be reduced to a slimy condition and not fit for use.—T. BAINES.

Flower Garden.

Auriculas.—"Delta" does not seem satisfied with what I stated about the woolly aphid, but I decline to discuss it further.

He first took exception to what I stated on the treatment of infested plants, and brings forward a remedy which he says he has tried and has not been successful. But I am prepared to say that my remedy, if properly applied, will be effectual. On the authority "of one of our most distinguished vegetable physiologists," "Delta" further states (p. 308) that watering the plants with paraffin, as he recommends, is beneficial. At the time I gave a word of warning against this practice. If it is preferred rather to follow "Delta's" advice who, according to his own showing, has lost the largest private collection in the south by one disaster, then it is no fault of mine. I never use manure water for Auriculas, but those who do will no doubt try the paraffin, and duly report thereon in these columns. Since writing last week the weather has changed to fine and warm, causing a large increase in the autumn bloom. A letter just to hand from Mr. Simonite, of Sheffield, states that in his collection the autumn bloom is unusually plentiful. At least 25 per cent. of the large plants in our collection are showing flower trusses. Still water carefully, ventilate freely, and keep the plants quite free from insect pests.

Carnations and Picotees.—All who are growing collections of these will now be busy amongst them, removing and potting the layers, or planting them out in beds of fine soil to be afterwards transplanted. Each layer must be carefully raised out of the ground. If roots have been formed the plant may be cut off, if not, press it into the ground again, to remain until roots appear. If it be intended to plant out into the open ground, the beds should be prepared for them by being deeply trenched, and, if necessary, some rotten stable manure should also be worked into the ground, but it ought not to be nearer the surface than 6 in. Clumps of the commoner border varieties are much appreciated when placed near the front of herbaceous borders. The best way to manage them is to layer the shoots in the manner as recommended for the choicer varieties, and allow the plants to remain where they are layered. Good rich sandy loam and manure should be placed round the roots. Such clumps as these produce scores of blooms during the season.

Dahlias.—The fine weather suits these, and we are still getting masses of very fine blooms. There is no further attention required than to tie the stems to the sticks, and allow the plants to produce as many flowers as they will. Such flowers are very useful for cutting, and if they do not attain the size of exhibition blooms they are none the less useful for room decoration. The single-flowered kinds, such as *D. coccinea*, *lutea*, and *Paragon* ought to be grown in every garden. The plants may be carefully lifted at the first signs of frost, and taken into a Vinery from which the Grapes have been cut, or a similar place, where they will continue to produce flowers for several weeks.

Gladioli.—Though late, the season for these has now come. The few fine days and warm nights we have had has caused the flowers to open finely. If the spikes are cut just as the first two or three blooms expand the others will open indoors if placed in water to the top of the stem. If there are any seed pods ripening they should be gathered just as they begin to burst. Lay them on paper in a dry airy place, where they will open in a few days and the seeds fall out. A green caterpillar is at present busy in eating the flower buds before they appear out of the sheath, these should be at once sought for and destroyed.

Pinks.—No time should now be lost in planting these in the flowering beds. Instructions have already been given as to the preparation of the ground. The plants should be carefully lifted and a hole dug out for their reception large enough to contain half a spadeful of good loam and manure; place this compost carefully round the roots. The plants should be 9 in. apart each way. A few of the best named Pinks are Blondin, Bertram, Boiard, Cristabel, Devise, Dr. McLean, Dr. Masters, Emerald, Emily, Excelsior, Freedom, Godfrey, Harry Hooper, John Ball, Lady Craven, Mildred, Mrs. Mitchell, President, Reliance, Shirley Hibberd, and Victory. In making up a collection such sorts also as the following should not be omitted: Lord Lyons, rosy purple; Lady Blanche, pure white; Anne Boleyn, Derby Day, and Mrs. Pettifer. These are quite distinct in type from the florists' section, and are much valued as cut flowers.

Pentstemons.—These are still flowering most freely; the stems from each plant are numerous and quite loaded with flowers. All the attention they require is to see that the stems are supported with sticks; but where they are planted in beds the stems support each other. The seed-pods must be removed, as they tend to check the production of flowers. Cuttings must now be put in. There are always plenty to be obtained at this season; the small side shoots at the base of the stems are the best. Insert the cuttings in pots or boxes of fine sandy soil, and place in cold frames or hand-lights, as may be most convenient. Shade them from the sun and water them moderately.—J. DOUGLAS.

Indoor Fruit.

Pines.—The growth of these, on account of the ungenial season, is necessarily immature, so now that the days are shortening and daylight moreover obscured by autumnal fogs, all available light must be taken advantage of, therefore all the glass of the pit or house should be thoroughly cleansed. Discontinue syringing overhead, and water but sparingly. It is very probable that many plants may this season fail to show fruit at the proper period, for, notwithstanding that the appearance of the growth is all that could be desired, there has been no sun to consolidate the tissues. It will therefore be wise to apply additional artificial heat, with free ventilation, and but little moisture in the atmosphere or at the roots. Suckers that were planted as early as January and February ought most certainly to show fruit without this exceptional treatment, and should now be kept rather cool—say about 65°—and dry both at root and top; at the same time guard against the too general practice of withholding water till the foliage is half parched; such treatment is neither good culture, nor in accordance with physiological principles. All the young stock should be finally overlooked preparatory to wintering, and any that are likely to become pot-bound should have a shift at once; give them plenty of room, and keep them in gentle growth for another month or so. The smooth Cayenne and Charlotte Rothschild varieties—the best winter Pines—that are now swelling fruit, should have weak guano water once weekly; of course, if the drainage be defective a weekly supply might prove injurious, but only under such circumstances.

Vines.—This is a season in which it may truly be said that it is more difficult to keep Grapes than to grow them. From many quarters we hear complaints of Grapes damping off and cracking, Hamburgs in particular. Unfortunately under such unusual atmospheric conditions the usual remedial measures are of little avail, but in hope of arresting the evil, recourse should be had to these remedies. First of all, remove all decayed berries as soon as perceived, for the mould spreads most rapidly. Keep a constant but gentle warmth in the pipes to ensure the air of the house being light and buoyant, and when the outside atmosphere is inclined to be so, open the ventilators wide and increase the heat in the pipes, in order to effectually expel stagnant moisture. Thorough ripeness, which has been almost impossible to attain this season, is no doubt the best preventative, and the fact that the Hamburg variety is affected the worst is due to the tender nature of the skin of the berry. The long-keeping varieties are rarely subject to the evil, and even then, it is because they have not been well ripened; hence the necessity to still continue the fires so long as there is any doubt on the matter. Outside borders, the Vines of which are carrying fruit, must now be protected from all further rainfall, for a chill at the roots, even if it does not cause cracking or damping, will most certainly aggravate it. If not already done the earliest Vines ought now to be pruned, the borders renovated, and the houses cleansed. The Vines ought to have a complete rest of at least six weeks. In the meantime protect the borders from rain by shutters or tarpaulin, and also from frost by a thick covering of Bracken or long litter. As a rule more time can now be spared for additional work, and it is also the best time to get together all materials for making Vine borders. If the soil be dug and stacked previously to the winter, any injurious insects, &c., in it would probably be destroyed by frosts, whilst the soil would certainly be benefited by exposure, provided it did not get sodden. Precautionary measures in regard to this point should therefore be taken.

Peaches and Nectarines.—The previous remarks in reference to these have urged the desirability of thinning out all superfluous shoots as soon as the fruit is gathered, in order to render the ripening and full development of the buds more certain by the free action of light and air. If the trees have suffered from spider, thrips, or fly, well wash them with the garden engine, and syringe daily till the parasites have entirely disappeared. Inside borders will still require water, though not so much as when in full growth. It is a gross error to ever allow the borders to become dry, for this is the principal cause which predisposes the trees to drop their buds before they are expanded. In all forcing operations, we ought, as far as possible, to imitate Nature, and a valuable practical lesson is taught in regard to the matter of watering, if we only take into consideration the large amount of water that Peaches get in the open air when in a resting condition, yet how rarely do they shed their buds! If the trees in the early houses have entirely shed their leaves, any pruning required may be done at once, and the houses made tidy for the winter. If the lifting and replanting of gross growing trees were done when advised, the roots will by this time have started into the fresh soil. They must not lack water, but be kept gently at work; a light mulching of stable litter over the border would greatly assist the formation of roots by maintaining an equable condition both of moisture and temperature. The houses should be kept as cool as possible. Those that are to be planted this autumn should be commenced at once, as the most suitable time

to plant is just before the trees lose their foliage. In selecting varieties early and late kinds should be chosen for the same house, as by this means the supply of fruit may be had in succession for a much longer period.

Strawberries.—The remarks on these (p. 222) are still applicable in every particular, for, unfortunately, the weather still remain, unchanged. It will be necessary to place the plants in their winter quarters as early as possible, for though they are apparently so robust they are still immature, and a sharp frost would severely check them. Our plan of wintering consists in plunging them in cinder ashes in turf pits, and protecting them with shutters in severe or very wet weather; at other times they have full exposure and are watered when required. By growing the variety Vicomtesse Hériéart de Thury, the production of Strawberries in autumn and winter is rendered an easy matter, as we have numbers of plants in pots now splendidly set with fruit. I have gathered good fruit from plants in the open air several times during the past fortnight, and if the weather should prove favourable there will be a plentiful supply for some time to come. The fruit gathered from the open ground is the produce of the earliest forced plants, which were planted out early in April, and from which our best present season's runners were obtained. Those that are fruiting in pots were also forced in the spring in 5-in. pots, and afterwards shaken out and repotted in fresh compost in pots of the same size. Still, I think the production of autumn Strawberries superfluous, as they will not be appreciated at a season when other fruits are so plentiful; yet it is well to know that they can easily be had if required.

Figs.—Established trees are still fruiting very freely, but the season is getting so advanced that, taking into account how valuable an early crop of Figs is, it is preferable to sacrifice the remainder in order to obtain a crop early; therefore the trees should be gradually inured to the full amount of ventilation that can be given till finally, if practicable, the lights may be entirely removed for a short time. Any trees in pots that have been placed in the open air to induce rest must be occasionally examined to see that they are not sodden on account of imperfect drainage. The safest position for them now is a cool orchard house or pit, as a few degrees of frost would seriously injure any fruit-bearing spurs that are not thoroughly ripened. Hitherto we have grown no other kind than the Brown Turkey, but a few days ago we had the privilege to see a large house containing several scores of plants of the Negro Largo variety, which in every respect were very fine. This has been added to our stock under the impression that it may even supersede the Brown Turkey; at any rate, it seems to be a first-class variety for pot culture.

Melons.—The season for these has been but an indifferent one, so that its close can scarcely be regretted. Swelling fruits will require abundant bottom and atmospheric heat in order to ensure good quality. Water will not be required much now; at the same time it is well to remember that dryness is adverse to the production of good fruit. A moderate supply of water, well preserved foliage, plenty of air, and warmth, never fail to produce high-flavoured Melons.—W. W.

Kitchen Garden.

Happily the weather has at length sufficiently improved as to permit of the speedy eradication of weeds, which is now imperative in order to admit all the air possible to the over-succulent growths of Broccoli, Sprouts, Cauliflowers, and Cabbages, so as to harden their tissues. Old beds of the latter prove so extremely valuable as Sprouts that they are worthy of special attention at this season, such as the removal of all decayed leaves, and even some of the largest that are not decayed, so as to induce the development of Sprouts. The ground should also be deeply stirred, not only for the destruction of the weeds but for the aëration of the soil. With us Brussels Sprouts have grown so abnormally tall that by way of keeping them upright we have had to earth them unusually high, and are now removing a portion of the stem-leaves, so as to admit light and air to the Sprouts. The earthing up of all the Cabbage tribe that are large enough for the operation, should be done at once for the sake of protection from the effects of the wind, and also for the free action of the air to the land; any other benefit derived from such a practice is of a doubtful nature, and if it were not necessary for the reasons above given, the earthing up system had better be abandoned. Both Celery and Cardoons require attention as to earthing, and should be tied with bast previous to the operation, in order to prevent the soil getting into the centres of the plants. The Celery-fly is unusually prevalent this season, and we find a sprinkling of soot applied once weekly an effective antidote, for though it does not destroy the pest outright, it hinders the spread of it. Cauliflowers that are now turning in, will need daily attention to keep them from injury by frost; break the leaves over the flowers, or, if a quantity be ready for use, and it is found necessary to prolong the supply, take them up with the entire stems, and hang them in a cool shed,

head downwards; in such a position I have known them keep for six weeks. Veitch's Autumn Giant and Sutton's King of the Cauliflowers are both excellent autumn and early winter varieties. By far the best early variety I have yet grown is Dean's Early Snowball. It is at least three weeks earlier than that excellent kind the Early Dwarf Erfurt, with heads at least equal to it in size, and in colour much superior, being almost pure white; it is here valued so highly that no other early kind has been sown for spring use, and the plants are now being planted out in handlights, a dozen in each, and in early spring will be thinned to four or five. The lids of the protectors will not be used till there are appearances of sharp frosts, as it is necessary, to safe wintering, that a sturdy hardening growth should be encouraged from the first, for if the plants, either by neglect of airing or overcrowding in the seed-beds, get drawn, but-toning will certainly follow. Prick out all the reserve plants in any sheltered spots. Where protecting material could be easily applied in the event of severe frosts, any that are to be wintered in cold frames should now be got out also; but meanwhile, as in the case of those in handlights, they should have the fullest exposure. Lettuce, Endive, and Herbs for winter use all demand particular attention at the present time, so that there may be no scarcity when required. Protection should be in readiness, as frosts may now occur any night. A few Tomatoes have, at last, ripened against south walls, and any not yet ripe, and that are of a size large enough to be used, should be cut, and, if hung in a warm airy house, will ripen perfectly. In our case we have found it necessary to practice this method, as the plants are badly attacked by the Potato disease. The storing of Beetroots and Carrots will soon be necessary, but as the former are small and still growing, it will be better to leave them till real danger is imminent. As a rule we winter them in the ground, and use Bracken or straw for protection, and by this method the roots are more tender than when pulled up and stored in sand. Look over the stores of Potatoes and Onions in wet weather. The latter will keep best if bunched and hung up rather than laid on shelves. This season they are so full of water that decay is sure to be prevalent, and following the above advice will ensure their better preservation. In the forcing department, Rhubarb and Seakale will soon demand attention. Apples being scarce, Rhubarb will be in great request, and it will therefore be advisable to introduce a batch into a warm temperature at once. Give abundant ventilation to French Beans in pits, and from now all the sowings will do best in pots; to keep up a continuous supply it is necessary to sow a batch fortnightly. Tomatoes that are fruiting indoors should have the growths kept thin and the fruit also; they may then be expected to continue in fruit throughout the winter. "Vick's Criterion" is the best of all kinds I have yet tried for pot culture.—W. W.

Parks and Open Spaces.

Herbaceous borders should now be carefully looked over, removing all decayed stems and leaves which would otherwise give shelter for insects and other pests, as they are now unusually numerous, and every possible means should be taken to destroy them—such as hand-picking and spreading lime, soot, &c., over the surface of the ground. If these precautions are neglected many valuable plants must inevitably suffer from their depredations. A clean cut is most essential in everything connected with pruning, so it is important that a sharp knife should be used for cutting away the woody stems, or much damage may result to the stools of some kinds in consequence of the loosening of the roots and splitting the stems. The soil must be forked between the plants and all vacancies made good by dividing old stools, &c. Pansies, Daisies, Arabises, Aubrietias, and such-like spring flowering plants should be put out at once, so that they may establish themselves before severe weather sets in. Bulbs of various kinds should also be planted in the most open spots, placing a thin layer of silver sand beneath them to prevent rotting and accelerate the formation of roots. For this purpose Hyacinths, Tulips, and similar kinds which flowered last spring will be found extremely useful if they have been properly treated and stored. They should be planted in clumps of six, eight, or ten, and from 2 in. to 3 in. apart; a small stick should be placed in the centre to prevent injury when digging or stepping on the borders, and as a guide when mulching them for protection during the winter, if necessary. Herbaceous plants, it must be remembered, do not ripen their stems and foliage simultaneously, therefore only those whose stems are ripened should be cut down, as many kinds would be thus injured if they contain active sap. Many churchyard gardens, town squares, and similar places will soon present a bare appearance, which will prevail throughout the winter in consequence of the injudicious selection of shrubs in planting. Strange to say, many still persist in planting such evergreen trees, shrubs, and Conifers which have not the slightest chance of thriving, they are therefore unsightly and a continuous source of trouble and expense. In places where planting is scanty, the bare ground is always an eye-

sore. My idea of a shrubbery is that it should be formed by various kinds of plants, with the foliage harmoniously blended, and planted sufficiently wide apart so as to obviate overcrowding. From time to time they should be pruned or even taken away where it is desirable. Where specimen plants are required they should be planted singly, as I consider the shrubbery is certainly not the place for them. As it is useless to plant varieties that are quite unsuitable, it is far better to plant those possessing qualities that render them capable of thriving in smoky districts, though they may not be the handsomest. Amongst the best shrubs for such positions are undoubtedly the Privet, Euonymus, and Aucuba. Of Privets there are several varieties which can be recommended, such as the oval-leaved, the Japanese, the evergreen, the Box-leaved, &c. Of Euonymuses there are also several kinds which may with safety be planted, the green-leaved varieties being the best and strongest. All these, as well as the Privets, naturally form pretty shrubs, and should not be clipped into all kinds of shapes, but allowed to grow freely. The Aucuba is too well known to need description. In wet seasons when the foliage is kept in a fairly clean condition the leaves of these shrubs present a fine lustrous appearance. The varieties of Forsythia and Rhamnus will also do well in town gardens. The broad-leaved kind of the latter grows into large specimens in a very few years. The Rose of Sharon (*Hypericum calycinum*) is a well known and excellent shrub for forming undergrowth, and for planting on the borders of plantations, &c. Amongst deciduous shrubs the varieties of Ribes are perhaps the best, and should always be included in the list. The Sumachs, too, are very useful for such places. The planting season being near at hand I advocate a trial of these shrubs, allowing one shrub to the square yard at least. In all small gardens there should be facilities for washing the foliage of shrubs with hose when necessary. After planting, the surface of the soil should be covered to a depth of about 2 in. with well-rotted manure or horse droppings mixed with road scrapings in equal proportions, the latter collected off flint metalled roads is the best for the purpose.—C. DENNIS.

Extracts from my Diary.—October 13 to 19.

FLOWERS.—Moving variegated Alyssums and Verbenas from cold frames into greenhouse. Cutting Holly hedges, Cotoneasters and Jessamine on walls, and nailing in shoots to cover the wall. Shaking out Pelargoniums from old pots and re-potting them. Taking up Souvenir de la Malmaison Carnations layered outside, potting them, and placing them in cold houses. Shifting cuttings of zonal Pelargoniums from 3-in. to 5-in. pots. Potting a few Pelargoniums and Fuchsias for winter blooming. Sponging Stephanotis and Allamanda on roof of stove. Putting in cuttings of Roses. Planting border with Violets and also one with Violas, Wallflowers, and Daisies. Taking up Spiræas from outside border and potting them in 5-in. pots for forcing.

FRUIT.—Gathering the remainder of Apples, viz., Wellington, Golden Reinette, Royal Russet, and Norfolk Beefing. Tying and stopping Melons in houses. Gathering Sweet Chestnuts and storing them away in fruit room. Looking over Grapes in late Vinery and cutting out laterals and shanked berries.

VEGETABLES.—Gathering Tomatoes and placing them in Vinery to ripen. Sowing Mustard and Cress in boxes in heat. Trenching border for Tripoli Onions. Putting first batch of Osborn's Forcing French Beans into 7-in. pots. Tying and stopping Tomatoes in houses. Giving earliest Celery a final banking up. Tying and thinning out shoots of winter Cucumbers, and fumigating for the prevention and destruction of greenfly. Sowing Gilbert's Selected Parsley in pans. Turning Mushroom manure. Top-dressing Cucumbers.—R. GILBERT.

What's in a Name?—The cut-leaved variety of our Western prairie Dock is called *Silphium terebinthaceum* var. *pinatifidum*; the Russian Daisy of our borders, *Chrysanthemum Tchihatchewii*; an annual Composite we grow, *Achropappus schkubrioides*; the Climbing Hydrangea, *Schizophragma hydrangeoides*; our wild, white-fringed Orchis, *Habenaria blephariglottis*; and a common window-basket plant, *Chlorophytum Sternbergianum*.—*American Agriculturist*.

Chloride of Lime.—A French contemporary states that if a little of this be spread on the soil, rats, mice, and insects will at once desert it. Plants may be easily protected by it from insect plagues, by simply brushing over their stems with a solution of it. It has often been noticed that a patch which has been treated in this way remains free from grubs, while the unprotected beds round about are literally devastated. Fruit trees may be guarded from their attacks by attaching to the stems pieces of tow smeared with a mixture of chloride of lime and hog's lard. Ants and grubs already in possession will then rapidly vacate their position.

THE INDOOR GARDEN.

ARISTOLOCHIA RINGENS.

UNDER the above name two very different species have been confounded. The true *Aristolochia ringens*, of which the accompanying engraving is a correct representation of a portion of a living plant which flowered in Messrs. Veitch's nursery last month, does not appear to be generally known in European gardens. Indeed, so far as we are aware, this is the first time that this species has flowered outside of a botanic garden in Europe. We remember having seen it in flower at Kew in 1863, and we secured specimens for the herbarium at the time, which exist as a record of the fact. But although so little known in Europe, it has been introduced into East Indian gardens, and it is also cultivated in Guatemala, Central-America. It is a native of New Granada and Venezuela, and, according to Grisebach, in his "Flora of the British West Indian Islands," also of Jamaica, but this is probably an error arising from a slip of the pen in the Kew herbaria, where one of Purdie's, apparently a New Granadaian specimen, is written up "Jamaica, Purdie." The flowers vary considerably in size, according to the vigour of the plant, sometimes attaining a length of 8 in., but usually they are only about 5 in. or 6 in. long; and the colouration is equally variable in intensity. On a pale ground we have a netted venation of dark purple. The tubular portion of the flower is paler than the lips, the ground colour of the upper lip passing into purple. Sometimes the leaves are as much as 7 in. or 8 in. across. In such a numerous genus as *Aristolochia* it is difficult to say which are the most ornamental or most curious. Many persons would not regard any of the kinds as really ornamental; and it is a fact that the most showy ones require a large space in which to develop their full size. Upwards of 150 species are known, and they are widely dispersed in tropical, sub-tropical, and temperate regions, excluding South Africa and some of the Pacific Islands. *A. ringens* requires a warm greenhouse, and attains the flowering state in a moderate space of time. It was sent to Messrs. Veitch by the late Mr. G. Wallis, who collected it in New Granada. Among hardly species the North American *A. Sipho*, a deciduous trailer or climber with ample heart-shaped leaves and small inconspicuous flowers, is the best. It rapidly covers a large space, but it requires some support; and it is a useful plant where bold foliage is suitable. The flowers have a green tube tinged with purple, becoming gradually smaller upwards, then suddenly expanding into a horizontal, nearly circular limb. *A. Clematitis* is an effective, erect-growing, herbaceous kind, with clusters of small yellow flowers. It is a suitable plant for the "wild" garden. There is perhaps not another genus in the vegetable kingdom which exhibits such a variety in the form, size, &c., of the flowers. Those

of the last are little more than 1 in. long, and the tube is very narrow in the middle, and gradually expanding upwards into an open mouth, and prolonged on one side only in the form of a lip. The three-tailed kind (*A. tricaudata*) is an arboreous species with large oblong leaves, and dark purple and white flowers, the broad open tube of which is prolonged into three slender tails, 3 in. or 4 in. long, reminding one of the flowers of some *Masdevallia*. Goldie's Birthwort (*A. Goldieana*) is perhaps the most extraordinary of the whole of the species. It has, with the exception of *Rafflesia*, the largest flowers of any known plant. On a double-sized plate of the "Botanical Magazine," which is as large as a page of THE GARDEN, a single flower could only be represented half its natural size. In shape it is like an enormous three-lobed vase (each lobe ending in a short tail) nearly 18 in. across the top, and narrowing downwards into a cylindrical tube obliquely,

The Gaping-flowered *Aristolochia* (*A. ringens*), half natural size.

bent upon itself, the lower position forming the foot of the vase. This singular plant is a native of Old Calabar, in western tropical Africa, where it was discovered by the Rev. W. C. Thomson, who succeeded in introducing living specimens into the Glasgow Botanic Garden, where it flowered in 1867. Of course this gigantic plant can only be grown in a spacious hot-house. *A. grandiflora* is a Brazilian species with flowers as long as those of the last named, but the limb of the perianth or floral envelope is developed on one side into a single long slender tail nearly a foot in length. Another very curious species from the same country may be seen in flower in the Palm stove at Kew at the present time. It is (*A. ornithocephala*) which has flowers similar in shape to those of *A. ringens* but about three times as large, the upper lip being dilated into a limb 6 in. to 9 in. wide. It may be mentioned that what we have called the upper lip is perhaps more correctly the lower, and it is uppermost on account

of the flowering branches being pendent. Messrs. Veitch have, or had, living plants of an equally curious West African species, *A. promissa*, the singular flowers of which extend into three tails sometimes as much as 2 ft. in length. One might go on almost indefinitely pointing out the peculiarities of various species. Besides the large growing species noted, there are many others of smaller dimensions, suitable for the lovers of the curious among plants who have but little space. Thus *A. trilobata* is a slender climber with flowers resembling the small pitchers of a *Nepenthes*, but bent on themselves in the opposite direction, and the part answering to the lid of the pitcher prolonged into a slender twisted tail 6 in. in length.

W. B. HEMSLEY.

Two Rare Orchids.—There are now in flower in the Pine-apple Nursery two interesting Indian Orchids, viz., *Luisia Psyche*

with creamy white petals each about 1 in. in length, and a labellum of the same width, curiously corrugated with a blackish crimson-like enamel, the whole flower greatly resembling a beetle; and *Luisia brachystachys*, the yellow lipped variety, the flowers of which are small but curious.—JAMES O'BRIEN.

TREATMENT OF ODONTOGLOSSUMS.

I HAVE read with much interest the remarks of Mr. O'Brien at page 305 in reference to this subject. Such practical articles are worth much. Still, I consider in the case of *Odontoglossums* that in seeking to discover the conditions which best suit them one might be doing "a dangerous thing." No one has attempted to show that these plants may not be cultivated more or less successfully under what is called cool treatment. It is no doubt desirable, from a nurseryman's point of view, to show that any subject can be grown by this or that method that is likely to be popular with the many, but the object of the gardener is to discover the right way, modify it as he may afterwards. There are two or three points broached in Mr. O'Brien's paper which it would be interesting to know more about. Firstly, if he finds it necessary to remove his *Odontoglossums* to a perfectly cold house with a north aspect by the beginning of May, why does he remove them to a warmer house at the beginning of September, when the temperature outside is considerably higher than in May? Secondly, in almost all miscellaneous collections of cool *Odontoglossums* that I have seen, the plants were in all stages of growth towards autumn, some just maturing their pseudo-bulbs, and others with these parts but partially developed, or at a stage when it is never desirable to rest an Orchid which has pseudo-bulbs to mature. Would Mr. O'Brien recommend all these to be treated alike? In other words, would he submit the matured plants and the growing ones to a minimum temperature of 45°? as the general tenor of his remarks would lead one to infer. It is a sound practice in my opinion to maintain a growing temperature until all such plants have matured their growth. Lastly, I should like to know what kind of growth the finest of Mr. O'Brien's plants of *O. Alexandræ* and *O. cirrhosum* made between May and September in the north house, the length of their growths, and the size of the bulbs, as well as the number of flowers produced to a spike on plants so treated for the last few years? I am not prepared to deny Mr. O'Brien's assertion that the pseudo-bulbs of *Odontoglossums* are formed as quickly in a temperature of 55° as they are in one of 75°, because under the treatment given them by me they make two sets of bulbs in a year, but those made during the summer are the largest and the best. In the rage after cool Orchids we are, I think, in danger of running to the other extreme. There are many kinds recommended in some trade lists as "cool" Orchids, which, to subject them to such treatment, would be very unwise. I have seen not a few collections of *Odontoglossums* or cool Orchids, but none of them treated in the manner described by Mr. O'Brien. He lays much stress on the supposed fact that the cool system suits small growers. Apart from the fact that it is quite as often convenient for smaller growers to grow their plants in a warm house, such as a Vinery, what is to hinder those who grow their plants in an unheated frame or house to give them as high a temperature in summer just as easily as a cool one by simply economising sun-heat a little more? C.

TRAINING PLANTS IN POTS.

NEARLY all plants under pot culture require some little training in the way of pinching, pruning, or supporting, and fast-growing plants are improved by being cut back occasionally rather closely, more especially after flowering. Any plants that are capable of supporting themselves in an erect position do not require stakes. Those that have a loose, rambling habit may be brought into shape by pinching when the shoots are young, which will, if properly attended to, give a clumsy-looking subject a graceful appearance. To stake a plant well requires a trained eye and skilful fingers. Some acquire the art naturally, whilst to others it is a difficult task, hence the reason why so many ungainly-looking specimens are met with. The addition of a few slender twigs, if adeptly placed, will often improve a plant considerably. Of course, for home use the plants might be quite as well without so much setting up; but, unless they are skilfully manipulated, they will not do for exhibition purposes. Therefore, those who aspire to take a leading position at exhibitions must learn to train plants neatly and with as few sticks as possible. Small neat sticks, painted green, look the best, and can be made in bad weather. Those that are made from double laths, that is, deal laths of a double thickness, that will easily bend, are the most suitable material and are readily procurable. A large number may be made in a short time, and afterwards a thin coat of green paint will preserve the wood and make them look less conspicuous. As it must be a

disadvantage to the plant to have the ball pierced, and perhaps the roots injured by having sticks thrust in, therefore as few as possible should be employed, and these should not be inserted in the ball deeper than is necessary in order to obtain the requisite firmness. Most plants will require to be gone over and have their supports and ties re-adjusted annually and most, if not all, of this work should be done, as much as possible, during the dull season.

E. HOEDAY.

THE ZEBRA-STRIPED RUSH.

OF the many kinds of leaf variegation amongst plants there are few that have the markings arranged in transverse bars. Notable instances of this kind of leaf marking are the plant under notice, and the Zebra-striped Grass (*Eulalia japonica zebrina*), illustrated in *THE GARDEN*, Vol. XIV., p. 263, which is one of the most beautiful of hardy Grasses. The Zebra-striped Rush is apparently a form of our common native species (*Juncus communis*). Like the Zebra Grass it originated in Japan, and similarly has reached Europe by way of America. It has been introduced by Messrs. Veitch, from a plant in whose nursery the annexed woodcut was prepared. It is a striking plant when associated with others, as its peculiarly rigid habit of growth and singular marking stand out in bold relief. Though it has not been

The Zebra-striped Rush.

grown entirely in the open air, it will most probably prove to be quite hardy and retain its variegation, and if so, it will make a capital subject for planting amongst other moisture-loving plants.

W. G.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Dendrobium primulinum.—For a useful, easily grown, and thoroughly free flowering variety to grow as a companion to the useful *D. nobile* I do not know a better than the one named above. The last edition of Williams' "Orchid Manual" describes *D. primulinum* as a fine subject for exhibition, and says it is rare, but it is probably plentiful now. It formed the greater bulk of a quantity of Orchids collected by a friend of my employer, and sent here from Burmah twelve months ago last May. All the plants appear to be seedlings, for scarcely any two are alike, some being so inferior in the flower as to be comparatively worthless, while others are large, beautiful, and slightly fragrant. The flowers are all more or less white and pink, but in some of the varieties the lip is broad and pure white and the other parts of a rosy or purplish-red tint. All flower late in spring and the blossoms are borne along each side of the stem. This kind is an exceedingly free grower; though much withered on arrival, all grew strongly and flowered last spring. This season they have made shoots at least twice as long and as thick as

those which they made last in their native habitat. The consignment also contained plants of the beautiful *Dendrobium chrysotoxum*, some of which have proved very inferior, having small greenish-yellow flowers, while in others they were of the other extreme. In the same importation we were fortunate in securing a large and healthy mass of a broader leaved and larger flowered variety of the *Cypripedium Boxalli* than I have yet seen.—J. S. W.

Ficus repens for Edging.—Although this plant is usually seen growing on walls, I find it very useful as a pot plant for edging any kind of stages on which plants are arranged for effect. Single plants from cuttings, potted in from 3-in. to 6-in. pots, and allowed to hang down naturally, soon make suitable plants for the purpose, as they become quickly furnished with gracefully pendent shoots, which form a pleasing fringe of green. It is too often the case that stone or brick-supported stages in conservatories become green and discoloured after a few years from the consequent dampness, and nothing hides this defect or increases the effect of a well-arranged group of plants on the stages so well as a fringe formed by this plant.—J. GROOM.

Storing Bedding Pelargoniums.—Though these have proved a failure in the open air this season we cannot afford to discard them, and we are now making preparation for storing a large number of last years plants of the scarlet flowered type, as they are not only much larger at planting out time, but as a rule they are more floriferous. When a display is required early in summer, old plants should be freely mixed in the beds, while for supplying flowers for furnishing vases they should always be used, as even in favourable years young stock plants require the greatest part of the season to acquire well furnished specimens. The best plan to adopt is to lift the plants before they are in the least injured by frost, then strip off the largest leaves, leaving the small terminal ones. Do not cut the shoots in at all, but defer that operation till spring when every point will make a good plant, and if cut down in autumn the old plants are much more likely to damp off. They should be placed moderately close in pots or boxes in light sandy soil, and one good watering given to settle the soil around them, after which they should only have enough water to keep them from shrivelling. They may be wintered in any pit or house where enough heat is available to keep out frost and dispel damp. In spring, as the days lengthen, they may be shaken out and potted or placed in boxes according to convenience, and will always well repay the labour bestowed on them.—J. G.

Tropæolum Lobbianum Perfection.—This rich-coloured climbing *Tropæolum* is now in fine flower at Heckfield, where it is grown in large pots in a cool house. The shoots are trained to wires. Here it blooms with marvellous abundance, and will do so all the winter, unless very severe frost intervenes; but other plants are grown in a warm house to give a supply of flowers if the others should fail. As a flower to furnish a rich glow of colour in winter, this kind is unrivalled, and it is remarkable that a garden of any pretensions should be found without it, grown either for vase decoration in the summer or for winter use.—A. D.

Primula sinensis.—It may be of interest to know that in an average season there is not much difficulty in wintering these *Primulas* in a cold frame. I have now plants in good health which were during last winter in an ordinary garden frame. To protect them from the severity of the weather the frames had wrappers put over them at night, but on every favourable opportunity the lights were slightly opened, and in this way they passed the winter and bloomed freely in the spring. I am persuaded that cold frames might with a little constant attention be made available for wintering many plants that are supposed by amateurs to need a considerable amount of heat.—HUNTLEY BROOK.

Filmy Ferns.—I have read with interest the notes lately contributed to THE GARDEN on the hardiness of Filmy Ferns, especially that at page 310. The peculiar beauty of these Ferns, and the fact (apparently not well known to many amateurs) that they will grow where scarcely a blade of Grass will live, render them of special interest to any persons living in places unfavourable to ordinary vegetation. My experience during last winter was perhaps somewhat exceptional. I dug out of the almost solid clay a hole 2 ft. deep, over which I placed three sheets of glass, and during the severe weather, when the thermometer registered 20° to 30° of frost, I covered the glass with a piece of ordinary packer's canvas. In this hole *Todea superba* passed the winter without a frond suffering in the least degree. In another similar place were wintered *Todea pellucida*, *Hymenophyllum demissum*, *Trichomanes radicans*, and others, with complete immunity from the severity of the weather. Several other kinds would no doubt be perfectly as hardy, if placed under similar circumstances; the experiment is well worth trying by those who possess several duplicates.—HUNTLEY BROOK, *Bury, Lancashire.*

TREES, SHRUBS, AND WOODLANDS.

WATERSIDE PLANTING.

THE formation of plantations by the seaside has already been treated of at some length in THE GARDEN, Vol. XIV., page 427. I was as much surprised as pleased to find from a note (p. 290) that, in addition to the trees recommended for sea-shore planting, the handsome *Pinus insignis* is also well adapted for such situations, as is proved by the success which has attended the specimens planted at Bodorgan, in Anglesea. The deep Grass-green colour of its leaves, which are very closely arranged on the branches, and its habit of branching very low, render it altogether peculiarly appropriate for bleak situations by the waterside. When planted upon a dry soil it ripens its wood very early in autumn, and its liability to become affected by frost is thereby much lessened, as this is generally the cause of its failure in severe winters when planted upon a rich moist soil in a low lying district. An unbroken expanse of water, unless it be a sea, bay, cove, &c., and, consequently, diversified by the ebb and flow of the tide is seldom an object of much interest when its banks are bare of trees or unbroken by bold and irregular masses of rock. When, however, its margin is embellished by trees and shrubs the water, like a mirror, reflects the objects upon its banks, which to the observer even appears to be multiplied. Tree vegetation may be considered as the natural accompaniment of water, and as such it may not only clothe the banks, but also give apparent connection to different lakes, and partially conceal outlines and boundaries, giving in each case variety and soften or tone down any prevailing harshness.

Besides the intrinsic beauty of water-side trees, which alone is sufficient to commend them to the notice of all lovers of Nature, they are admirably adapted, when skilfully arranged, to put a generous deceit on the spectators, and effect the noblest designs by easy methods. Thus the smallest rise of ground upon the opposite bank may, by skilful planting, be made to appear much greater than it really is. The smallest island, if planted near its margin with spreading trees, behind which others of a fast-growing kind are placed, in order to thrust forward the outer ones, will gradually appear to become larger. The same remark is applicable to the planting of all projections. Where an embankment or a dam is necessary to keep the water at different levels, its entire length may be concealed by judicious planting. The apparent form and extent of water may also be considerably altered by a skilful management of the light and shade to be obtained by planting trees or opening out spaces amongst thick masses near the water. In order to give extent, as much light as possible should be thrown upon the distant parts; and if the banks slope back gently they admit of the reflection of more sky, and thus enlarge the picture. Unless, however, there is high ground behind, most of the advantages of reflection are lost. Water upon high ground, unless it be to a great extent surrounded by trees, causes a constant glare of light. Another disadvantage under such circumstances is that in such a position it generally becomes very much foreshortened.

For the purposes of the planter the form of a sheet of water is not a matter of primary importance, as the more irregular the outline the greater is the scope afforded him, and enables projecting portions to be made bolder, and bays and inlets apparently deeper by throwing a denser shade upon the recesses. The planting should be proportioned to the extent of the water, as heavy masses of wood appear out of place beside small lakes; so very small clumps or too many single trees produce an opposite effect in connection with larger ones. With regard to the kinds of trees suited for waterside planting it may be remarked that, speaking generally, Pines and Firs do not harmonise with such situations; the Cedar and Pinaster are decidedly the best of the Coniferous kinds. The overhanging branches of the Cedar, and the rugged bark, the irregular top, and dense whorls of branches upon the Pinaster, give them a peculiar fitness for such positions. The Plane, Wych Elm, Beech, Hornbeam, Ash, and Alder are also well adapted. The Acacia when growing near water generally sends up a great number of suckers. The deep fresh green of the Alder, combined with its luxuriance of growth, renders it an object of interest, and in old age the Alder is by many people scarcely to be distinguished from the Oak, and this character well adapts it for substituting the appearance of an Oak plantation, where a continuous effect is required, in soil too wet for the latter. The branches of the Wych Elm and the Plane are remarkably striking in situations where they overhang the water. The White or Silver Willow, with its long and extremely flexible shoots, which rapidly grow when planted in a deep, good, and moist soil, is even more graceful than the Weeping kind. The Weeping Ash, when its head is not allowed to become too much rounded, is particularly suited to sloping banks. The Birch, also, by the lightness and gracefulness of its form is also well adapted to the waterside.

The greatest difficulty, however, is often experienced in the management of the undergrowths near the margins of lakes and streams, for where these consist of subjects which have to be cut back periodically to prevent their growing into, and thereby injuring, the standards, the naked appearance of such banks is highly objectionable and unpicturesque. On this account it is far better in such situations to plant Thorns, Hollies, Yews, Buckthorns, and even Laurels and Elders, and thus secure a permanent screen.

In planting for effect in the line of sight between the house and the water's edge, it should not be forgotten that a few trees near the eye have an equal effect with a much larger number farther removed; and that, while deciduous trees of various kinds will in time, by the help of a little pruning, grow out of the way so as to admit of distant objects being seen between their stems and underneath their heads, the Coniferous kinds will, by the extension of their lower branches, shut out more of the view year after year. These are points which should never be lost sight of in planting in a line with water or any other distant object of interest.

Though the trees named above are, among the denizens of our woods and forests, probably the best that could be selected for the waterside, almost any kind of planting is preferable to the formal waving lines which are but too commonly seen upon the margins of dressed lakes and pieces of artificial water—if, indeed, it can be called dressing that completely strips the object of its solitude. Not even those flowing lines and endless curves which “lead the eye a wanton chase” will give half the charm to a waterside path that is imparted by judicious planting. Here, as elsewhere, all abruptness in planting should be avoided, for the real beauty and interest of the work centres in transitions which are so gradual as to be almost imperceptible, and in which no violence is done to Nature. Formal rows or regular clumps of trees by the waterside are in the highest degree objectionable, so likewise are prominent fences of any kind; for the reflecting powers of the water by doubling the objects add greatly to their formality.

Pluckley, Kent.

A. J. BURROWS.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Virgilia lutea.—The beauty of the foliage of this tree in the early autumn season renders it worthy of more extensive cultivation than is generally bestowed upon it. A fine specimen, standing at the bottom of the terrace and close to the boundaries of the park at Surrenden-Dering, in Kent, and which has a background of masses of Elm and other large-sized trees, is at the present time an object of great beauty. Its bright yellow and orange coloured tints are conspicuous among the dark green of the surrounding foliage and the lighter hues of the spreading Planes.—A. J. B.

Well Shaped Hedges.—Apropos of hedges in general I have been particularly struck by that on each side of the Brighton and South Coast Railway as far as I have travelled along it, *i. e.*, from London to Brighton, and thence to Portsmouth. It has been recently clipped, and its shape is that of a wedge, with its base on the ground. It is 2 ft. thick at the bottom, tapering quite to a point at the top. The height seemed about 4½ ft. Such a shape must always ensure a dense and luxuriant growth, and the density of this is something remarkable. Perhaps an “Old Sailor” may not be much of an authority on such matters, but in spite of that I will venture to affirm that such a line (or lines rather) of hedges should serve as a model anywhere. They are of quickset throughout.—ASHLEY LATOMBE, *Commander, R.N.*

Plantations.—Upon the drier soils nearly all kinds of young trees have made extraordinary growth during the past summer. In many situations however, upon the more retentive lands, Chestnut, Birch, Oak, and some other kinds which were polled last season, have died back altogether or made no progress. On such soils the work of filling up will be heavy and expensive. No season for the last twenty years has furnished stronger evidence of the great advantages of thorough drainage and early planting. Acorns are conspicuous by their absence, Ash-keys are abundant, the fruits of the Spanish Chestnuts are very slow in coming to maturity, and those of the Horse Chestnut and Walnut are scarce. Altogether the season is a very unpromising one for the collector of tree seeds. Even the hedge Nuts have produced but an indifferent crop.—A. J. B.

Remarkable Beeches.—Near to Parkanour, in Athlone, the residence of Mr. J. Burgess, stand two Beeches which, at a short distance, resemble heaps of leaves more than trees. They were found in the woods sixty years since, and are from 6 ft. to 8 ft. in height and 15 ft. diameter, and of den e drooping habit. Upon creeping inside, I found them to branch off at 2 ft. or 3 ft. from the ground, where one was nearly 5 ft. in circumference. The arms and branches are not unlike corkscrews. The inferior branches and

matted rubbish, if cleared out, would greatly improve their appearance, as the singular growth would then be visible. They might, if sent out, become a valuable adjunct to the upright Yew, which flourishes in Ireland, the finest of which I have yet seen was 21 ft. high and 12 ft. through, and well filled in the centre.—C. ISHAM.

Darwin's Barberry in Towns.—We have recently recorded the value of this as a seashore shrub, and we also notice that it has done very well as a London plant, even in the horrible clay of the Regent's Park.

THE LIBRARY.

Rural Affairs.—We have received Vols. VII. and VIII. of Thomas's “Rural Affairs” (Tucker & Sons, Albany, N. Y.), a work full of practical information, and illustrated profusely with useful, and often pretty, woodcuts. Some of the matter is reprinted from the *Country Gentleman*, which has long had the reputation of being the leading American agricultural journal, and in this handy form it will be more convenient than in the pages of a large journal. The horticultural papers are in all cases marked by care, thoughtfulness, and practical knowledge of the subject. When any aesthetic question, such as landscape gardening is touched upon, there is evidence of taste and right feeling for what is best in the art. Many practical hints and neat woodcuts in these volumes would be useful to English as well as American readers. We take the following extract as showing its utility:

Propagation of Pansies, Violas, and Calceolarias.

—October is the right time to propagate these, some preferring the first and some the latter part of the month; but we have generally found about the second and third week to be as suitable a time as any. Than these, no bedding plants are more easily propagated, and none are easier kept during the winter. Any rough frame, made with four boards about 1 ft. wide each, and nailed together, answers perfectly for holding and wintering hundreds of them in; or they will do without a frame if dibbled in at the bottom of a south wall, where they can be protected with cloths, mats, Fern, or other material during severe weather. Young Pansies and Violas will bear a great deal of frost; but Calceolarias are more tender in this respect, though in all other ways they succeed under the same treatment as the Pansies and Violas. They strike root freely in a mixture of loam, leaf soil, or old Mushroom manure, and sand. In damp positions a layer of the latter should also be spread over the surface to the depth of 1 in., as this will keep the surface sweet during the short dull days. The cuttings of the Calceolarias which we prefer most are the hardy points of the shoots without bloom; but the

Pansies and Violas throw out plenty of side shoots which answer well for cuttings. They are all made in the ordinary way by trimming their lower ends with a sharp knife. The best cuttings are those about the length of one's forefinger, and they may be planted about 1½ in. or 2 in. apart each way. At times, when we had no more suitable accommodation for these cuttings, we have rooted quantities of them in old boxes, and these were shifted about as the weather or other circumstances might require.—CAMBRIAN.

GARDEN DESTROYERS.

THE PLUM TREE TORTRIX.

(ANTHESIA PRUNIANA.)

AT times the caterpillars of this very common little moth are very destructive in orchards and gardens where Plums and Cherries are grown, for in the spring, just when the trees are coming into blossom, these little caterpillars are hatched, and at once ensconce themselves among the flowers and commence feeding on them; when the flowers are over they change their quarters and betake themselves to the

The Plum Tree Moth.

leaves, on which they feed until fully grown. If Plum and Cherry trees have been much attacked by these insects, it will easily be understood that the crop must suffer very considerably in quantity, for not only is a large proportion of the flowers destroyed, but, if the leaves are injured to any great extent, the vigour of the trees must consequently be much impaired. It is always very difficult to recommend any effectual means for destroying insects which attack orchard trees, as, on account of their size, it is almost impossible to reach all parts. It appears that in the case of this insect there is nothing to be done when in the egg or caterpillar state, beyond gathering and destroying the leaves which are rolled up, for these generally contain a caterpillar or chrysalis. The stems of the trees should always be kept free from Moss and loose pieces of bark, as such places afford shelter during the winter months to the second brood of chrysalides. It is also better to keep the ground near the stems of the trees free from Grass or other herbage for the same reason. Smaller trees, such as espaliers, and those trained against walls, can be more easily dealt with, and I should recommend that these trees should be carefully looked over when in flower, and that all blossoms which appear to be attacked or affected in any way should be picked off; any leaves which are curled up should also be removed, taking care that the caterpillar does not drop out of the leaf and escape during the operation. The common Blackthorn or Sloe is attacked in the same manner by this insect. The moths appear about the end of March or in April, according to the season, and

lay their eggs near the buds. The caterpillars hatched from these eggs attack the flowers, and, when these are past, they resort to the leaves, which they roll up and fasten with silken threads, and in this shelter they live and feed on the leaves. When fully grown, they line their habitation with threads, and become chrysalides, from which the perfect insects emerge in August. The caterpillars of the second brood have to live entirely on the leaves. When fully grown, they descend, and, finding some sheltered place under Moss or among Grass, become chrysalides, remaining in this condition until the spring. The Plum tree Tortrix belongs to the family Tortricidæ, most of the members of which, when in the caterpillar state, are injurious to vegetation. I have already in these articles called attention to two very destructive species (on September 21, 1878, to Bergmann's Tortrix, and on November 2, 1878, to the Codling Moth). This family may easily be distinguished from its near relations, the Yponomeutidæ and Tineidæ, when in the perfect state, by the shape of the wings, which are much broader, and in the upper wings the front margin has a decided shoulder, and is nearly parallel to the opposite margin. It differs also from the Geometridæ in the shape of the front wings, which in the latter family are very large, and have little or no shoulder, and their margins are far from parallel; in the caterpillar state they also differ, for the caterpillars of the Geometridæ have only five pairs of legs, and move in a peculiar manner, on account of which they are called loopers, while the caterpillars of the Tortricidæ have eight pairs of feet, and move in the ordinary manner. The Plum tree Tortrix measures about 5/8 in. across its wings when they are fully opened. The front pair are of a brownish-black colour for more than the basal half of the wing; the remainder is whitish, clouded with grey, the tip and end margin being greyish. The lower wings are greyish-black. The head, thorax, and body are greyish. The caterpillars, when fully grown, are about 1/2 in. long. When first hatched they are of a pale yellow colour, but after the second change of skin they are dirty green, sometimes almost grey, with the head, the back of the first joint, and the extremity of the last joint of the body, and the first three pairs of legs, shining black. The body is covered with little black tubercles bearing a few stiff hairs. The first three, the sixth, seventh, eighth, ninth, and last joints bear legs. The chrysalis is brown; the edges of the segments are furnished with a row of small spines.

G. S. S.

[In my paper on the Cabbage moth in THE GARDEN of Sept. 13, I gave by mistake its generic name as Hadena, by which it is known by many authors; but Mr. Stainton, whose nomenclature I intended to follow, uses, I find, its better-known name of Mamestra brassica.—G. S. S.]

NEW YORK HORTICULTURAL SOCIETY.

THE annual autumn exhibition of this society was opened to the public at Madison Square Garden, in New York City, on the evening of the 17th of September last. The building in which it was held is large and well adapted for a display of horticultural products, being now brilliantly illuminated by electricity, which it may be remarked is the only artificial light adapted to a proper display of flowers. A most attractive novelty in the floral department was a tank of exquisite Water Lilies, contributed by Mr. E. D. Sturtevant, of Bordentown, N. J. Among these was a genuine Nilotic Lotus, with huge nodding flowers standing above the circular leaves; also fine specimens of *Nymphaea dentata*, *N. odorata*, and a beautiful and interesting hybrid from Indian varieties, with delicate pink blooms. All these were open-air plants, some having borne flowers 12 in. in diameter during the past summer. Some rare evergreens were shown by Parsons & Sons; although the display was larger in the way of deciduous shrubs with variegated foliage. Their Japan Golden or Sun-ray Pine was very pretty, as were also their brilliant feathery Japanese Maples. Mr. John S. Burt contributed a fine collection of Crotons, Palms, Achimenes, Caladiums, and a few of the new Dracenas. Mr. Louis Menand and Mr. Isaac Buchanan had also some fine specimens in this class. Mr. W. C. Wilson showed a splendid Croton of the Earl of Derby sort. The display of cut flowers was unusually large and attractive, Mr. Peter Henderson and Mr. James Vick being the largest exhibitors in this way. Mr. Roenbeck, the celebrated Fern enthusiast of New Jersey, was again on the ground with a beautiful collection. The show of fruit was exceptionally good, perhaps better than any that ever graced an exhibition table in the metropolis. Chief among these were the fine collections of Messrs. Eliwanger & Barry, E. P. Roe, Peter Henderson, and others. The variety was large and the handsome colouring and form of the specimens shown gave evidence of careful culture fine healthy growth. The vegetable display was also one of considerable merit. Henderson's new seedling Potato, St. Patrick, attracted much attention, and beautifully smooth, amber-coloured tubers they were. For these as well as other vegetables he was awarded

a prize, and also for his Caladiums, Dahlias, Verbenas, cut flowers, and foreign Grapes. Some of the other principal prizes were as follows: To Messrs. Ellwanger & Barry, for Grapes and fruit; to Mr. Roenbeck, for Ferns; to Mrs. Morgan, for Orchids; to Mr. W. C. Wilson, for Marantas and Crotons; to Mr. Isaac Buchanan, for Lycopodiums and Selaginellas; to Mrs. Davidson, for autumn leaves and pressed Ferns; to Messrs. Woolson & Co., for hardy herbaceous perennials; to Mr. James Vick, for cut flowers, Lilies, and Asters; to Mr. J. S. Burt, for stove and greenhouse plants; and to Mr. L. Merrand, for Orchids, Agaves, Succulents, and Erica.

Kingston, N. Y.

H. HENDRICKS.

ANSWERS TO CORRESPONDENTS.

Weeds on Walks.—Can you inform me the best way to eradicate weeds on garden paths? Is sulphuric acid and water a good cure?—K. [Sulphuric acid applied at the rate of 1 lb. to 20 gallons of water will effectually destroy weeds on walks, and all other vegetable matter, so that in using it is necessary to exercise great care so as to prevent the liquid touching Box edgings, Grass verges, &c. It is also desirable to use the liquid in dry weather only, for if a heavy shower took place directly after the application, the acid would be washed into the verges, &c. Provided these precautions are adopted, sulphuric acid is one of the best weed destroyers on walks that can be named. Gas water, used in a pure state, is also an effectual remedy, but the same precaution must be taken to prevent it injuring the verges.—W. W.]

Grapes Splitting.—I should be glad to know the best time to light fires for an early Vinery. We generally light the beginning of January or February, and have always had abundance. Last year we lighted at the end of September, and only had twenty-five bunches. How soon should Grapes be ripe after forcing has begun? About fourteen days since some Grapes began splitting (not ripe), white and black; the former were worse. Last year the same Vines are quite good, and not one berry is split. In the same house some white Grapes are splitting as above described. We close the house early, and have had a fire twice only just to keep out frost in winter, but it is not a forcing house. The Vines planted are inside the house, which is 25 ft. in width, 16 ft. high, 180 ft. long, with a southern aspect. We do not keep the house very damp. Some Peaches on high walls in this house were very good and ripe six weeks since. In a long house 250 ft. long by 12 ft. with a height of 10 ft., where there was never a fire, I notice some white Grapes splitting. They are planted inside entirely against a wall. They are all white and just ripening. Why do the Grapes split? and what is the cure?—K. [The best time to begin forcing must always depend on the state of the Vines. Forcing should never be attempted unless the Vines have been well ripened and have had at least two months rest; and this period your Vines could not have had, seeing that they were only started in January or February, and were again started into growth at the end of September. The wonder is not that you had only twenty-five bunches but that you had any at all. In your case we should consider the beginning of the year the best time to begin forcing, and the Grapes ought then to be ripe by midsummer. The splitting of Grapes is most generally caused by atmospheric moisture, but sometimes by superabundant root moisture; as you apply so little artificial heat, there can be no doubt whatever that in your case the splitting is caused by humidity in the atmosphere. The remedy is therefore obvious, viz., apply artificial heat, and free ventilation in order to carry off the moisture.—W. W.]

Gas Lime and Ammoniacal Liquor as a Manure.—Could you tell me whether either gas lime, ammoniacal liquor, or sulphate of ammonia makes a good manure for flowers, such as, say, Roses, Geraniums, Abutilons, annuals, &c., or if so, which is the best and how should it be applied?—E. L. [Gas lime is a dangerous compound to use fresh from the works, but by exposure to the atmosphere the sulphates soon decompose. The best way to use it is to mix it with vegetable refuse or ordinary garden soil, and not apply it to the ground till it has been mixed for at least three months; all the deleterious gases will have then escaped, and it then makes a good manure for all soils that are benefited by the application of lime. Certainly it is not a good manure for flowers, but for vegetable crops generally it is beneficial. Ammoniacal liquor or sulphate of ammonia is a good manure for all the kinds of plants mentioned, but it requires to be used in a very diluted state, say one of the liquor to ten of clear water, and the plants should not be watered with it oftener than twice a week. The nature of this manure is to promote wood growth and deep green foliage at the expense of flowers, which tendency can only be obviated by the use of weak solutions, and not too frequently applied.—W. W.]

Asparagus Dying from Wet. In answer to a question put by "B. H." at p. 313 of THE GARDEN, relative to the causes of his Asparagus dying from wet, M. Godefroy-Lebeuf, the celebrated Asparagus grower of Argenteuil, writes in the following terms: "It is not only to the autumn rains that we must attribute the failure of the Asparagus crop in Wales, but also to the defective method of culture which is there practised. I am almost convinced that the Asparagus spoken of by "B. H." was not earthed up during the autumn. The effect of this operation is not only to allow free access of air to the stool, but it also helps it to ripen. Under these conditions the plant is much better able to resist the damp and cold than when it is covered over with the thick layer of mould which is generally left on the stool. In support of what I advance I can give an instance of a plantation made in a peaty soil, which is inundated every winter, but Asparagus grown in it succeeds most perfectly. The facts quoted by "B. H." only occur in Asparagus plantations in which the old system of culture is adopted. What I state, however, must not be taken in too absolute a sense, for I will not guarantee that all soils are naturally fitted for growing Asparagus; but they can all be made so at a very small cost. When we have at our disposal only slightly porous soils that are very damp in the winter, we must drain them by digging a number of trenches, following the incline of the land, of from 1 ft. 8 in. in depth, 2 ft. in width, and 10 ft. apart. On the beds thus formed we throw the soil which we have taken out of the trenches. The soil of the beds, consequently, is heightened by so much earth. This operation should be performed early in the autumn, so as to give the newly made beds time to settle down, as Asparagus must always be planted in firm soil. At the time of planting we must follow the directions given in the articles which have lately appeared over my signature in THE GARDEN, taking care, however, to plant less deep in proportion as the soil is damper or more compact. As it is always convenient to have sufficient soil close at hand for earthing up, we must plant at greater distances apart when the stools have not been planted deeply. We must also keep the spaces between the rows of Aspar-

agus well dug, so that the water does not make a natural gutter of the trenches in which the Asparagus is planted. The facts cited by "B. H." have only occurred this year in a few localities in the northern and midland districts of France, and they have always been accounted for by the fact of the precautions spoken of above not having been adopted. I am obliged to "B. H." for calling attention to this subject, and I shall always be pleased to answer any questions relating to Asparagus which the readers of THE GARDEN may put to me. Mr. Robinson, by calling special attention to the subject of Asparagus growing in England, has placed a fresh source of profit in the hands of the English market gardener, who may learn a useful lesson from what is going on at Argenteuil and in other districts where Asparagus is grown on a large scale. In these localities there are no poor growers, and at Argenteuil this year's crop of Asparagus will enable our farmers to feel little or nothing of the ruin that would otherwise have fallen on them. Owing to the hopeless condition of our Vines our Grapes are still green, and those which have taken colour have damped off immediately. The loss to our Vine growers, who generally produce 200,000 hectolitres of wine in good years, may easily be guessed, when it is stated that the labourers in the Vineyards gain five and six francs a day, all of which will be lost this year; but by growing Asparagus they will, at any rate, make up for part of their fearful losses.—GODEFROY-LEBEUF.

E. P. Legge.—If our correspondent would call on Mr. Godefroy-Lebeuf some day, at Argenteuil, when the culture or produce might be seen, he would probably soon conclude that there is yet a good deal to be changed in its culture here. The articles alluded to were written for the climate of France and not for England, though, as there is so very much in common between the climate of northern France and England, we thought the ideas of a good French cultivator could not fail to be interesting in days when more attention is being paid to this vegetable. In your estimate of the French Asparagus we can in no way agree.

Fruiting of Cycas revoluta.—D. G.—The fruiting of this Cycad is not an uncommon occurrence, though it is doubtful if the plant has been in the place for fifty years without producing fruits.

Soursop.—The length of time required for Passiflora fruits to ripen depends upon the circumstances under which the plant is growing, the weather, and the kind it is, in ignorance of which we are unable to answer you.

Italia.—Try Louis Van Houtte's nursery, which is in the neighbourhood you mention.

Stoes.—We are unable to refer you to any place for the purpose you name.

W. G. Daintree.—Apply to M. Godefroy-Lebeuf, Argenteuil, France.

Names of Plants.—E. L.—The plant figure you allude to is that of *Ceropegia Gardneri*, a stove climbing plant belonging to the Asclepiadaceæ; it is a native of Ceylon.—H. G. W.—The Mullein is *Verbascum nigrum*, a British plant.—W. L. D.—It appears to be a leaf of *Ranunculus sceleratus* (Naiadaceæ).—C.—The Pears were not ripe; therefore cannot be named accurately.—S. B.—1, *Aster Amellus*; 2, *A. Chapmani*; 3, *A. versicolor*; 4, *A. grandiflorus*; 5, *A. Novæ-Angliæ*.—*Fern.*—1, *Lygodium scandens*; 2, *L. dichotomum*; 3, *L. japonicum*; 4, *Pteris serrulata*.—S. B. M.—1, *Rudbeckia speciosa*; 2, *Dahlia glabrata*; 3, probably a leaf of a *Silphium*; 4, *Anemone vitifolia* (distinct from *A. japonica*); 5, send again when in better condition.—*Dublin.*—1, *Berberidopsis corallina*; 2, is apparently *Callixene polyphylla*; 3, *Adiantum tenerum*; 4, a spray of an *Artemisia*; send when in flower.—T. S.—The Escallonia is a fine one, and we will endeavour to ascertain the name.—Z. Y. X.—*Retinospora squarrosa*.—F. F.—1, *Bupleurum fruticosum*; 2, *Alonsoa incisifolia*; 3, *Phlomis ferruginea*; 4, send when in flower.—*Subscriber.*—One of the numerous *Potentillas* of the European Alps, but from the scanty material sent it cannot be named correctly.—W. H. M. and H. B.—Next week.—C. B. K.—1, *Eryngium amethystinum*; 2, *Arctostaphylos Uva-ursi*; 3, *Aspidium Lonchitis*; 4, *Selaginella inaequalifolia*; 5, *Asplenium flabellifolium*.—J. McDonald.—1, *Polystichum Lonchitis*; 2, *Athyrium Filix-femina Victoriae*; 3, *A. F. promorsum*; 4, *Nephrodium decursivopinnatum*; 5, *Athyrium Filix-femina Rileyi*; 6, *A. F. multifidum*.

Books.—C. D.—"Enbridge's Domestic Floriculture," obtainable at our office.—H. W.—1, No. It is Rivers' "Orchard House," which can be obtained from this office also; 2, Yes.

Clematis.—Second Pruning.—It is not generally known that the species and varieties of Clematis may be induced to bloom the second time by cutting back the plant immediately under the part that bore flowers nearest the ground. Clematis Jackmanni, which blooms late in June, is only one instance where in a month or so after pruning abundant flowers appear; few varieties, indeed, surpass it in the freedom with which it thus blooms. When we consider how much the addition of this ever-blooming quality enhances the charm of the Clematis, it seems surprising that an understanding of the fact has not been more generally attained.

Hydrangea paniculata.—Fortunately for the varied attractions of lawns, *H. paniculata grandiflora* has at last obtained general acceptance as an ornamental shrub of the first rank. But we must not merge the attractions of the lesser in those of the greater, nor confuse *H. paniculata* with its variety *H. paniculata grandiflora*. Few indeed know or realise that such a shrub exists as *Hydrangea paniculata*, but it is a very distinct plant nevertheless, possessing valuable peculiarities of its own. Instead of blooming in August and September, it flowers late in June and early July. These flowers are smaller than those of *H. paniculata grandiflora*, with erect, instead of drooping, trusses or spikes of inflorescence. They are also of a pure white colour, that does not fade into purple and crimson decay, like *H. paniculata grandiflora*. The sterile flowers are, moreover, less numerous in the type than in the variety, and the leaves as well as the trusses of bloom are certainly smaller and less coarse. Practically *H. paniculata* is unknown to the trade, but none the less does it deserve honourable mention for its date of blooming and fine general habit. Our own specimens came direct from Japan through the medium of Mr. Thomas Hogg.—S. PARSONS, in *Rural New Yorker*.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

NOTES OF THE WEEK.

Botanic Garden, Cambridge.—We have much pleasure in announcing that Mr. R. Irwin Lynch has been appointed curator of this garden. Mr. Lynch had held, until recently, an important post in the Royal Gardens at Kew, where he had been for several years. His training there has specially fitted him for the management of such a garden as that at Cambridge, and we think the selection an excellent one. It would be difficult to say whether a man with a botanical training only, or a gardener merely acquainted with ordinary collections of plants and their culture, would do most harm in a botanic garden. Mr. Lynch combines the thorough horticultural training with exactly the kind of botany desirable in such a case—a very wide knowledge of living plants both hardy and tender. We therefore look to see the Cambridge garden assume, under his management, a very important place among our botanic gardens. The situation of the garden is a very desirable one, more open and airy than is usual in such places, and the extent is such as to allow of a better collection of trees than in the old gardens of the Chelsea type. The soil seems well suited to the health of a great many hardy plants, and we have seen many good plants and rare there during the past sixteen years. There is a fine belt of trees surrounding the garden, which when we last saw it was sadly in want of a careful overhaul. The trees had grown very much together, and many of them were spoiled. This belt carefully "gone over" and the more common species cleared away to give full room to the rarer kinds, and the margin broken and extended here and there, would form a very fine feature, and be a good arboretum in itself. The Cambridge garden, like most other botanical gardens, suffers a good deal from the common system of trying to arrange a garden as a book or herbarium is arranged. The true way is to have the full collections of important plants, but grow them where they thrive best and look best. We may hope for a healthy change in this direction at the hands of the young men now being appointed to our various botanical gardens. It were too much to expect them to do away at once with the dismal open air herbarium, but they may here and there make a beginning by showing that a good collection and a beautiful garden are in no way incompatible. We have more than once shown in THE GARDEN that the very best collections we have in the country are not unfrequently disposed in the most charming manner.

Pachytoma Thompsoni.—Of this extremely rare Orchid there is now a finely flowered specimen in Messrs. Veitch's nursery. Its bulbs, broadly lance-shaped foliage, and style of growth remind one of the kinds of Pleione. Its flowers are produced singly from the base of the bulbs, and are about 3 in. across, with narrow pointed pure white segments of waxy texture; the lip, a deep rich purple, is about $\frac{3}{4}$ in. long, very narrow, and much pointed, and has a singularly twisted appearance, forming quite a semicircle. Its wing-like appendages are greenish and copiously spotted with chocolate. Altogether it is a beautiful species and one that will undoubtedly find favour with lovers of orchidaceous plants. It was exhibited by Messrs. Veitch at South Kensington on Tuesday last, and was deservedly awarded a first-class certificate.

Kiosque in Regent's Park.—The note in THE GARDEN of last week led me to look at this, and I quite agree with the remarks therein made about it. It dominates and much detracts from the beauty of the fine sweep of ground west of the Central Avenue, and anybody may see who looks towards the Avenue from this, the largest expanse in the Park. The number of chairs and beaten paths, and all the other features of a tea-house of this sort are no addition to the charms of a public park, and, as you have well pointed out, are not necessary in this case, inasmuch as a few minutes' walk suffices to reach places where such a structure would not be so objectionable as in the centre of a park like this, and dominating the finest landscape in it.

Cynoches Warszewiczii.—Of all the singular Orchids that have come under our notice this is the most remarkable, and it is one of the most notable instances of what is called dimorphism, or the production of two kinds of organs on the same individual, that we have seen. It is far from being a showy plant, as its flowers are green in every part and consequently somewhat inconspicuous. One set of flowers are borne on a raceme from 15 in. to 18 in. long, and have narrow reflexed segments, a lip with about ten fringe-like

appendages, and a part which has a peculiar twist similar to that of a swan's neck; hence the origin of the generic name. The other flowers are very dissimilar as regards form, being much larger in every part, and in form more nearly resembling an ordinary Orchid flower; they are moreover borne on a short instead of a long stem. This remarkable plant was exhibited by Mr. Bull at the last meeting of the Royal Horticultural Society, where it attracted considerable attention and was awarded a Botanical certificate.

Carey's Crinum (C. Careyanum).—This lovely species, certainly one of the best of tropical Crinums, is now in flower in the Palm house at Kew, and is deservedly much admired. In foliage it scarcely differs from that of some of the commoner types, such as *C. asiaticum*. The flowers are somewhat larger, more shallow, and of a spotless white. They emit a delicious fragrance, which, in a small house, would be almost overpowering. It is to be regretted that these charming bulbous plants are not more generally cultivated than they are, a fact the more surprising when it is well known that they are amongst the most beautiful of tropical flowers. *C. Careyanum* is a native of the Mauritius and Seychelles Islands.

Illicit Commission.—As the bribing of persons holding offices of trust is now before the public, I venture to enclose a specimen just to hand of offers commonly made with the view of corrupting architects.—R. HESKETH, 13, *St. Swithin's Lane, E.C.*
"Dear Sir,—In anticipation of the approaching planting season, we venture to introduce ourselves to your notice, in the hope that you may be able to place some business in our hands. We hold an enormous stock of exceptionally fine and well rooted shrubs of every description, which we are prepared to sell at very moderate prices, and on any orders that you can introduce to us we shall be glad to allow you a handsome commission. Trusting you may hear from you, we are, dear Sir, yours faithfully, ———."—*Times*.

Autumn Flowers at Tooting.—Messrs. Barr & Sugden's grounds are now very gay with the autumn-flowering kinds of Colchicum and Crocus. Of the latter, *C. speciosus* is a beautiful species, with dark purple flowers delicately pencilled and feathered with darker lines. *C. pulchellus* is also a pretty kind; the violet-purple flowers with yellow throats and white anthers render it very distinct. Of Colchicums there are a great variety. The charming *C. speciosum* may be seen in many forms; some deep rose, others of a very pale tint, with the other varieties of every intermediate hue. The chequered kinds, such as *C. variegatum* and *C. Parkinsoni*, are also very attractive, and the singular markings render them highly interesting. The common kinds, such as *C. autumnale* with its several forms, and *C. byzantinum*, are, of course, very plentiful and make a fine display.

The Looking-glass Tree (Hertiera macrophylla).—A huge specimen of this handsome Indian tree is now an object of much interest in the Palm house at Kew, as it is bedecked with a profusion of small white blossoms disposed in pendulous branching racemes, and produced in dense clusters from the upper parts of the branches. The foliage, too, is handsome, as the leaf-blades are broadly lance-shaped, and measure about 1 ft. in length, with a proportionate breadth. The leaves, moreover, are especially attractive in a young state, being at first of a pinkish tint, afterwards changing to a bronzy hue, and finally to a bright polished green. The silvery appearance of their surfaces gives rise to the name of Looking-glass tree, a name which is perhaps somewhat astruse as their reflective property is but small.

Lilies in October.—We have been pleased to notice a brilliant bloom of Lilies in Professor Owen's garden during the past few days—Lilies of the tigrinum and auratum types. As regards Lilies many satisfactory changes have been effected in our gardens within the past few years, and if we can regularly count them among our finest hardy flowers of October, it will be a great aid to the beauty of the autumnal garden. The unfortunate season may, however, have much to do with it; this, and some varieties of *Lilium auratum*, often bloom late in the season. Lilies of the tigrinum type in brilliant bloom in October are not so often seen. They were growing well among Roses.

Meadow Saffrons in Tufts of Violets.—One of the prettiest combinations of Meadow Saffrons possible may now be seen in Battersea Park. It consists of several tufts of them springing from a mass of Violets, the deep green of which forms a capital contrast to the purple blossoms of the Saffrons. The Violets obviate the naked appearance the Colchicums have when springing from the bare earth.

Coriaria ruscifolia.—Though by no means showy, this shrub attracts attention on account of its graceful habit, and the pretty effect which it produces when in flower. In its native habitat it attains a height of from 10 ft. to 18 ft., and has long slender branches, which have a tendency to arch. The flowers are small and green, produced from the axils of the leaves in drooping racemes from 8 in. to 12 in. in length. It is a desirable

plant for associating with plants of a less graceful habit in a conservatory. It is abundant throughout New Zealand, and is also a native of Chili.

Early-flowering Chrysanthemums.—Now that the display in Mr. Parker's nursery, Tooting, made by the large masses of hardy flowers, which have for some considerable time been very effective, is on the wane, these showy autumn flowers are very useful for brightening the fading beauty of their companions. As in the case of other kinds of plants, they are disposed in rows with the colours agreeably harmonised. Though there is not a great variety in colour amongst them, they may, by judicious arrangement, be made very effective, as is the case here. Their dwarf habit is another point in their favour, combined with their remarkably free-flowering habit. There appears to be only about a dozen really distinct varieties, so a selection of the best is not a difficult task.

William Tillery Melon.—This oval, beautifully-netted green-fleshed Melon is now fruiting abundantly at Clumber. It is named in compliment to the late Mr. Tillery, of Welbeck, and is said, both at Thoresby and at Clumber, to be one of the best of late Melons. It received a first-class certificate from the Fruit Committee at South Kensington.

Bedding Plants in the London Parks.—The Board of Works has once more, according to annual custom, announced its willingness to give, to all who may apply through the proper quarter, some of the bedding plants that are about to be lifted from the parks. That this is done with a good intention there can be no doubt, but it is to be feared that the number of them wintered alive is but small. It would be far more charitable and useful if any spare plants in pots at the bedding out season were so distributed, as not only would these be obtained at a time of the year when the recipient might hope to reap from the gift some benefit, but also being established before the winter set in, they would pass through that trying season for town plants with comparative ease. Such liberality as this would be worth commendation, but such gifts as are now offered are of very doubtful value.—A. D.

New Crimson Stock.—This is flowering beautifully at Thoresby, and is much more brilliant in colour than the older Crimson. The Wallflower-leaved White is also a great acquisition, its glossy deep green leaves setting off the snowy blossoms to better advantage than the grey foliage with which Stocks generally are furnished. Deprived of Stocks, the flower garden at Thoresby would lose much of the gaiety which it now possesses, and they last long, and are also very useful in a cut state.

Catlin's New Pelargoniums.—We understand that these, including Lizzie Smith, Edgar Catlin, and Fanny Thorpe, which were certificated by the Pelargonium Society at South Kensington this year, have passed into the hands of Messrs. Carter & Co., by whom they will be distributed next season.

TREES, SHRUBS, AND WOODLANDS.

PLANTING TREES A GOOD INVESTMENT.

THE commercial stagnation and severe agricultural depression through which this country is now passing threatens to seriously affect the value of landed property, and to sadly reduce the incomes derived from that hitherto considered sure and almost inexhaustible source of national wealth. Among the number of uncertain and often conflicting suggestions for relief the reduction of rents is one of the most popular amongst the general community who do not own land, without any consideration for the hardships which must be borne by landowners whose whole returns are in the shape of farm rents. For such it is to be feared there is little hope of immediate relief; but the owners of well-wooded estates have no such cause for alarm, as the profits, or rents, derived from the produce of their woods are not subject to the same deterioration, through the badness of the seasons and other natural causes, as those of the owners of arable land. This, of itself, should be a strong incentive to all landowners to plant a certain proportion of their estates with suitable trees of a marketable nature, even on land which in more prosperous times would give a larger return under tillage. Many thousands of acres of arable land do not return the owners thereof so much as twenty shillings per acre annually, and all such land would realise a larger profit under a crop of suitable trees. This has been so often proved by the most plain and indisputable evidence, that it is really surprising to find that so few of the numerous proprietors of land, bringing in less than twenty shillings per acre per annum, have yet entered upon a systematic course of planting operations, with a view to increase the profits they derive from their less remunerative lands. It is certainly not desirable, if it were ever likely to occur, that every acre of low rented land be occupied with a crop of forest trees; but a vast

increase in the plantations upon such land would most undoubtedly be advantageous to the owners of it, and beneficial to the country.

However, it is upon the millions of acres of waste and almost worthless land, so far as agriculture is concerned, that the most profitable plantations can be made, and the owners of it should not allow the present favourable opportunity to pass without adding largely to the area under forest trees upon their estates. The low price of labour, and the ease with which any amount of it can be obtained at the present time, should be a strong inducement to all enterprising landowners to engage at once in planting, upon a judicious and well-arranged plan, all the waste land upon which trees will grow, and other properly chosen ground, upon their estates. A safer investment of money, or a more profitable one, cannot easily be found in these times, besides the great benefits immediately derived by the country, through the employment of the present abundant supply of surplus labour. Estate improvements of every kind can now be carried out in the most economical manner, and those who employ the greatest amount of labour at the present cheap rate will reap the greatest reward at a future and not far distant time, when trade and wages regain their natural buoyancy.

In carrying out the formation of plantations and all estate improvements, a systematic plan of operations should be previously decided upon. In devising a proper scheme, the most experienced skill is necessary to ensure the most suitable and well-arranged plan, in accordance with the necessities of each case, and with a view to realising the greatest profit combined with the best effect. Every care being taken to devise a proper plan, it should be strictly adhered to, and uniformly carried out, under the direction of the most practical skill that can be obtained. Permanent works of the nature of estate improvements require great experience and judicious forethought in designing, and an equal amount of thoroughly exercised practical skill is necessary to carry them out with the best results. The employment of inexperienced knowledge in devising, and unpractised skill in carrying out such improvements, is a frequent and inevitable source of annoyance and loss to estate owners, and they act wisely who take good care to avoid these unpleasant difficulties by taking the best advice and employing the best skill that they can procure.

Journal of Forestry.

Washingtonia filifera.—The Washingtonia of Kellogg, as applied to the mammoth tree of California having failed because the distinction between it and the prior genus Sequoia not being maintained, Wendland, a noted authority on Palms, now proposes this for the Pritchardia filifera, the famous Palm of the Colorado River, which he contends, from recent examination, is not a Pritchardia at all. This Palm seems unfortunate in finding a home in nomenclature. First it was Brahea, then Pritchardia, and now Washingtonia.—*Gardener's Monthly.*

Eucalypti in Ireland.—It may be interesting to know that the under-mentioned five kinds of Eucalyptus stood out uninjured in the Earl of Annesley's garden at Castlewellan, Co. Down. Fifteen varieties in small pots were planted out for trial at the end of August, and received no protection whatever. Ten of the varieties succumbed to the severe cold. E. coccifera, cornigera, Gunnei, Risdoni, and unigera were not in the least injured but grew vigorously, and have made fine plants this season.—R.

Hedges.—Your correspondent who describes the shape of the hedges by the side of the railway near Brighton (p. 338) need not travel far to see plenty of hedges of the same shape, as most hedges when newly trimmed are made narrow at top, but invariably get wider as they get older, as repeated trimming renders them liable to get so. Perhaps the most noticeable example of hedge trimming out of the common way is in parts of Cheshire, where they are cut into a triangular form; taking a section of them the base would be quite 4 ft. thick, and the height about the same, the top or apex being like that of a roof. I was told that cattle were more afraid of a hedge of this shape than of any other; whether this is so or not I cannot say, but as each district has its peculiarity, this was the prevailing one in hedges in the neighbourhood alluded to, while in Kent the idea is to keep them as narrow as possible, often not more than 1 ft. in a full-grown hedge; and in some places the boast of some farmers is that a hare cannot get out of their fields at any place but the gate, so close are they at bottom. Of course it is not every one that is so, but many are, where attention to keeping them clean has been attended to; but I would like to see or hear of trials made of other plants beside the White Thorn for hedges. It is doubtless an excellent plant for the purpose, and probably the best at present known, but it is possible others may possess a certain amount of merit; and if none of your correspondents give us their ideas on this head, I will on some future occasion try to do so.—AN OLD GARDENER.

THE FLOWER GARDEN.

NEW BEDDING PLANTS.

HAVING, during the summer now drawing to a close, grown, for the purpose of trial and comparison, some of the new varieties of soft-wooded bedding plants sent out this spring for the first time by two leading firms of Edinburgh nurserymen, viz., Messrs. Downie & Laird and Messrs. Ireland & Thomson, I think that a few remarks as to their respective merits and demerits, as they have shown themselves in my garden, in the south of Ireland, on the sea-board of Cork Harbour, may not be unacceptable to such of your readers as take an interest in this highly ornamental and useful class of decorative plants. To commence with the bedding *Nasturtiums* or *Tropaeolums*, of which three new varieties came to me named respectively *Clouded Gem*, *Glengarry*, and *Vesuvius*, I may say that the first, though a strong and vigorous grower, is yet of compact habit, producing large flowers of a bright orange, most of them finely streaked with a lighter colour, but the plant is not a very free bloomer; this fault may, however, disappear in a sunnier and more genial summer than that which has been vouchsafed to us this year. The second (*Glengarry*) is of a much lower-growing and compact habit, with smaller and lighter-coloured flowers, most profusely and continuously produced, and is a very pretty variety, and likely to be useful. *Vesuvius* is rather a coarse grower, but does not straggle; its blooms are of medium size, and of a fine deep glowing orange colour more or less streaked, but by no means so freely produced as in the case of the last-named variety. I may add that the Lambton Castle seedling *Tropaeolum* (named after its raiser, Hunter) has in poor soil been, and still continues, very bright and ornamental with me. In rich soil this variety runs too much to leaf, and does not flower at all so freely as in poor. Two new varieties of *Ageratum* were sent me, the one *Her Majesty*, from Edinburgh, though of a tolerably dwarf and compact habit of growth, has pale, dull-coloured flowers, and seems to me a variety of but little merit. The other, *Cannell's Gem*,

from Swanley, is by a long way the dwarfiest and best *Ageratum* I have ever seen, and seems likely to be a most useful and desirable acquisition for carpetbedding purposes, as it does not grow more than from 4 in. to 6 in. high, and produces fine deep purple-lilac flowers throughout the entire season with great profusion. A border of it inside one of *Mimulus moschatus Harrisoni* was exceedingly ornamental, and in a finer summer would have been better and brighter still. Only one new *Iresine* was sent out this year from the same nursery as *Ageratum Gem*; it is named *Brilliantissima*, and seems to be a highly-coloured sport from the old *I. Herbsti*, but like many highly-coloured varieties, it seems very deficient in constitutional vigour, and whatever it may do in a warmer and more genial summer, or as a pot plant for conservatory decoration, it certainly did no good out-of-doors with me this year, the plants hardly growing at all and being about the same size when taken up as when put out in June.

Five new varieties of *Lobelia Erinus* (besides an introduced species with golden flowers, named *L. lutea*) were sent to me mostly from Edinburgh. These were named *Pink Queen*, a variety with dark bronzy foliage and deep, but somewhat dull-coloured pink flowers; this variety is more curious than actually pretty, and a really bright rose-coloured variety with good-sized flowers is still a desideratum. *Lilac Queen* is, perhaps, the dwarfiest and most compact in habit of any variety yet sent out, the plants forming dense, round, little, ball-like cushions covered with small lilac flowers; this variety is capitally suited for edging a small bed with, and has been figured in the "*Floral Magazine*." *Mrs. Ellice* is a worthless variety, with a long straggling habit of growth and small thin pure white flowers. *Alba multiflora* is likewise a very inferior variety, also with a long straggling habit of growth, and much of it producing blossoms streaked with blue, and so not true to their pure white colour. *Lady Ross* is a vigorous, free, upright-growing variety with blooms of a

pleasing shade of deep blue with very small white eye. This is a very free and continuous bloomer, and one admirably suited for the late autumn season, as it is still covered with bloom-buds yet to open. The yellow-flowered species introduced from the Cape in 1774, and figured in "*Botanical Magazine*," vol. 32, in 1810, was almost lost to European gardens till recently re-introduced by a German firm at Erfurt. It is not a free bloomer, at all events in the open air, and is more curious than actually ornamental. W. E. G.

THE AUTUMNAL SPIRE LILY.

(HYACINTHUS CANDICANS.)

THIS is one of the most interesting of all large-growing recently introduced bulbous plants, and one which has proved to be hardy in many gardens, even after the exceptionally fatal winter of last year. Here, in the College Gardens, Dublin, a bulb planted by my predecessor, Mr. F. W. Moore, produced a spike 5 ft. 6 in. in height, bearing in all twenty-five flowers, and there are now some fine seed pods fast approaching maturity. The individual flowers on our spikes were exceptionally large, and being of snowy whiteness, and backed by a glossy dark-leaved Holly, they stood out with a fresh boldness that was the admiration of all our more discriminating plant-loving visitors. To many it was a novelty, and quite a little path was made across the border during its blooming season by those

who did not believe that "distance lent enchantment to the view." In waxiness and purity our flowers of this *Hyacinth* were, indeed, comparable with those of *Lapageria alba*, except that their effect in this instance was heightened by the black anthers which form such a prominent feature in the plucked blossoms so well shown in Mr. Hyde's engraving here annexed. Even in cold or bleak localities the plant might be grown in a corner, sheltered by plant-houses, or beneath a sunny wall, for it is well known that many Cape bulbs, such as *Crinum*, *Ixia*, *Watsonia*, and even such plants as *Hedychium Gardenianum*, *Lilium giganteum*, and tropical *Solanum* are perfectly amenable to open air culture, if planted close to the

Flowers of *Hyacinthus candicans*.

foot of a warm plant-house wall. As a general rule, however, this, *Hyacinth* is well able to take care of itself, if well planted in a deep, rich sandy border, sheltered from cutting eastern winds. A correspondent in the last number of *THE GARDEN* (p. 326) gives us valuable information of some large bulbs grown in pots at Chester: "They were left out in the open air during the whole of last winter, in pots plunged half their depth in coal ashes. On one plant were counted some forty flowers and buds, the stems being over 5 ft. in height." How valuable such a brief and definite note really is can only be fully appreciated by the born-lover of beautiful hardy flowers. A year's experience in an inch of print. Ah! how many of us go rather to the other extreme, and spin out our inches of progress into column-long articles.

The bulbs of this plant may now be obtained in quantity. I have seen them advertised at 10s. per dozen, but by the hundred they would be much cheaper, and for cut flowers the plant would be worth twice the money for its wealth of refined wax-like flowers. B.

Spring Flowers in Autumn.—I never remember before now to have seen so many spring flowers in blossom at this season of the year. Of course a great many of them have come out in a straggling and imperfect sort of way, but the following plants and shrubs have flowered here during the last fortnight: *Saxifraga crassifolia*, *Daphne Cneorum*, *D. Dauphina*, *Weigela hortensis nivea*, *Berberis Darwini*, *Pittosporum Tobira*, *Aubrietia purpurea*, *Primula veris*, *P. intermedia*, *P. denticulata*, *P. cashmeriana*, *Pyrus japonica*, *Gentiana acaulis*, *Erysimum rupestre*, *Corydalis lutea*, *C. cava altiflora*, *Coronilla Emerus*, *Linum luteum*, *Pansy Paul Pry*, and *Auriculas*. *Polygala Chamaebuxus purpurea* is well on in bud. It has been a strange year altogether, and this seems in keeping with it.—H. EWBANK, *Ryde*.

THE ROCK-GARDEN AT YORK.

THE extensive nurseries of Messrs. Backhouse & Son afford at any time of the year a source of much interest to those fond of plants; whether it be a ramble through the rich collections of exotics from tropical and temperate climes, the many acres devoted to hardy ornamental trees and shrubs, or the herbaceous ground and rock-gardens, which teem with hardy plant wealth, every class will be found to be thoroughly well represented and managed. To the lover of hardy flowers the last-named department has an especial interest, inasmuch as it has, for many years past, received the special attention of the firm. To see the gems of Alpine regions so thoroughly at home under cultivation is indeed a treat; but it is not under ordinary conditions that they thrive so well, neither is the rockery on which they grow of ordinary construction. To those accustomed to see only the cosmopolitan style of rockery, which may be met with in most gardens, the impressions on first seeing the extensive and massive rock-garden here are not readily forgotten. Compared with this the so-called rockeries which universally lay claim to the name are mere dry heaps of rubbish. Here the huge craggy mass, which in some parts rises well nigh 30 ft. in height, with the steep declivities dipping into a placid miniature lake, around which are formed cavernous recesses and miniature ravines of every size and conceivable form, yet so natural and picturesque, is only to be compared with choice glimpses of Alpine scenery, which the presence of the thick, deep, irregular belt of thriving Conifers, whose tapering habit of growth so characteristic in such regions, much enhances. But where is the Alp on whose surface can be found the plant life of mountain regions from every quarter of the globe? It is at a glance apparent that this Alpine garden, so unique in design and arrangement, has been constructed with one primary end in view, and that is, the imitation of, as far as practicable, the native habitats of the plants. Picturesque beauty, however, has not been lost sight of, for the ponderous masses of rock, which in some cases are several tons in weight, are superimposed in so artistic a manner as to be a fascinating imitation of wild Nature. No handiwork of the plasterer is here to be seen, no cunningly wrought layers of cement over masses of rubbish, such as some notable "rockeries" are constructed of, but pure natural stone quarried some miles distant from York. By a skilful arrangement, the tortuous and undulating paths and flights of rugged steps, which intersect in all directions every portion of the diversified structure, are conveniently seen, and yet so studiously devised as to compel the visitor to concentrate attention on particular points. What a vast variety of plant life does this rock-garden present to view! Below in the weird-looking, cavern-like recesses formed by massive blocks of overhanging rocks, may be seen revelling in native vigour, shade and moisture-loving Ferns, and amongst them the beautiful pellucid-fronded Killarney and other native filmy Ferns luxuriating with their even more beautiful congeners from the Antipodes the *Todea superba* and others, which have braved the severe cold of our climate in the snug nooks in which they are planted. The sides of the adjacent rocks, whose extremities are submerged and thus suck up abundant moisture, form a foothold for colonies of moisture-loving plants, such as *Butterworts*, *Parussias*, Ferns, *Droseras*, *Sundews*, &c., which everywhere sow themselves and grow in confused masses. Judging from their thriving appearance, their needs seem to be well supplied though they have but the bare rock and water from which to derive nutriment. Above there is every variety of aspect and degree of exposure, in order to suit the numerous requirements of all occupants; in fact, taken altogether, it is doubtful if there exists a hardy flower, be it Alpine or otherwise, that could not be accommodated exactly with its peculiar wants in such a rock garden as this. On the more exposed parts may be seen those that delight in the fullest exposure, provided their roots can penetrate the deep fissures of the rocks as they do here, while partially shaded positions are afforded for such plants as require less exposure, and actual shade is also provided for the denizens of woods and similar situations.

Any one intending to construct a rockery would do well to take a lesson from this one at York, for though its extent could be by no means imitated, in the majority of cases, still the principle of construction might be profitably studied, as it is on this point that many err more than in the selection of material of which it is to be constructed. That the proper way of adjusting stones in rockwork can be practised on even a small scale will be apparent to every one who has seen this structure, and but a short time ago I noticed a small rockery built in an exact imitation of the style of that in Messrs. Backhouses' nursery; though small, the arrangement of the stones and also the plants were quite in accordance with the original. This is but one instance of how a model may be imitated, and doubtless there are numbers who have practised the plan on a larger scale. If such an exemplary structure existed in the neighbourhood of London, it is doubtful if the ordinary grotesque piles one sees would be so prevalent, for persons would not tolerate the comparison, when it could be

remedied by simply altering the construction. If, for instance, there was a rockery worthy of the name in our national garden at Kew, so that the numbers of persons who seek advice on such matters could take a lesson, it would indeed be a boon. Besides, what a source of pleasure it would be, not only to those who are familiar with Alpine flowers from seeing them in their mountain homes, but also to the rapidly increasing community who are ever eager to obtain information as to the management of these beautiful plants, which may be grown by every one and in the smallest garden, provided they are at first placed under the necessary conditions of culture.

Instead of this, we have at Kew a paltry stony bank, placed under the shade of huge Elm trees, whose hungry roots form a network throughout the mass. It need scarcely be added that under these conditions Alpine plants will *not* thrive; consequently, many scores of lovely gems perish there annually which have been generously presented to the garden from all parts of the globe, and more particularly by English and Continental donors. With such enormous resources as these for acquiring a vast collection, combined with the fine position, unlimited space available there, and other exceptional advantages, Kew could have, and ought to have, an Alpine garden which would not only rival this unique rockery of the north, but be superior to any similar artificial structure known to exist, and constructed at a much less cost than it would take to erect and maintain a glass shed for housing some class of plants in which the public do not take interest, and from the scientific use that is made of them in a living state, might as well be in oblivion. But to revert to the main object of these remarks. The best time to see the York rockery is during May and June, when the majority of its occupants are in full beauty. At the time of my visit (a week ago) it was, nevertheless, far from being devoid of flowers for from many of the sheltered nooks were peeping the pretty nodding blossoms of the autumn-flowering *Cyclamens*, from the deep rosy-tinted flowers of the European kind (*C. europæum*) to the paler-hued and also spotless white blossoms of the Ivy-leaved Sowbread (*C. hederæfolium*), all of which are capital plants for enlivening rockwork and similar places in autumn and during the dull days of winter. Here and there on moist ledges were masses of the round-leaved *Pyrola* (*P. rotundifolia*), a pretty native plant, with spikes of pure white and deliciously fragrant blossoms, rising from a carpeting of deep green foliage. Primroses of all kinds grow unusually luxuriant here, and even the new Himalayan *P. rosea*, whose beautiful rosy blossoms first gladdened our eyes last spring, and which was considered a small-growing kind, is here found in large tufts, with leaves well-nigh 1 ft. long and of a bright deep green. It evidently likes a cool moist place, which also suits so well its handsome congeners, the *denticulata* and *capitata* section. Of the last-named kind there was a remarkably fine variety in flower. The pips were large, and the colour of the most intense rich purple invested with white mealy matter which formed a striking contrast. In flower also were a host of other beautiful plants, but comparatively few of the rarer kinds that are here abundant. As it is impossible to enumerate a title of the interesting plants that luxuriate here, these remarks must necessarily be restricted to a few of those which most attracted attention.

Amongst these were spreading masses of the European Alpine *Primulas*, all thriving admirably on the most exposed parts. The early-blooming *P. marginata*, which in most collections succeeds but indifferently, forms some of the largest of the patches; the effect they produce when covered with pretty violet-purple blossoms on a cushion of mealy leaves is most charming. This, by the way, must not be confused with the variety *marginata* of the yellow *Auricula*, which, though its leaves are similarly invested with white powder has, like the type, golden-yellow flowers. A point worth knowing in connection with the management of this Primrose is that it thrives best when planted horizontally in fissures; it is, moreover, far more effective than when seen in the ordinary way. The dense deep green rosettes of *P. spectabilis* are indicative that its requirements are well satisfied, for never have I seen such masses hitherto under culture; these also were chiefly grown in a horizontal position. The little Allioni's Primrose (*P. Allioni*), too, is as happy as in its mountain home, judging from its thrifty condition; indeed, one may see here, more or less largely represented, every Primrose yet introduced to our gardens; even the superb Himalayan *P. Stuarti* and Parry's Primrose from the Rocky Mountains, whose rich purple clusters of blossoms excite the envy of every lover of hardy flowers to possess it. Another host of beauties are the *Gentians*, of which the collection is particularly fine, from the common stemless *G. acaulis*, which is often met as an edging to garden walks, to that rare little gem of the Himalayas, which almost positively refuses to grow in our climate, notwithstanding the tender care bestowed on it. The charming *G. verna* of our own mountain districts is grown in abundance, and may be seen at every turn; this is perhaps the most satisfactory of dwarf-growing kinds, and the lovely cœrulean hue of its flowers is only surpassed by such as *G. bavarica*, which, unfortunately, is not one that will thrive everywhere. Besides all the common kinds, one

may see the rarer ones also, including *G. pumila*, *ciliata*, *brachyphylla*, *imbricata*, *Frœlichii*, &c., which in spring bedeck the rocky with their lovely flowers. Of the larger-growing species the new North American *G. affinis* was in flower; though not so showy as many of the others, it is a desirable plant on account of its free growth, compact habit, and rich blue flowers, which are produced abundantly. High in the most exposed portions, but so placed that its far-rooting, tiny threads can penetrate the deep fissures of the rocks, is that most exquisite Alpine gem the *Eritrichium nanum*. The difficulty attendant upon this plant under culture is apparently mastered here, if the appearance of the plants at present is any

nately one of the most difficult of all Alpines to manage under culture, but it is apparently at home here growing in a slanting crevice. Another rarity is *Crassiope fastigiata*, a plant which thrives so well at Glasnevin. There are at York broad masses of it, though it does not seem to grow so tall as at Glasnevin. It appears to require a partially shaded situation and a deep peaty soil. A similar situation suits the tree-like Club Mosses well, and they all flourish admirably here. It is to be regretted that such exquisite plants are not more known than they are, as they are totally unlike any ordinary type of plants, and can only be compared to liliputian Conifers. *Lycopodium complanatum* especially resembles miniature trees of

A Tuft of Mountain Flowers.

critterion. One of the principal points is not to allow the woolly foliage to be fully exposed to the weather; not that the plant is at all tender, for it is as hardy as the rocks themselves; but it cannot endure continuous wet on the leaves. The main portion of the stock is grown in frames, with the lights so arranged that while they effectually protect the plants from wet, there is a continuous current of air passing over them. This is a capital arrangement, and one that would suit many other woolly-leaved subjects.

Besides the various kinds of *Pyrola* that nestle in the moreshady nooks there are other Ericaceous plants of extreme rarity, such as the tiny *Andromeda hypnoides*, which is in itself a treasure, especially when studded with pretty waxy-white bell-like blossoms. It is unfortu-

the elegant *Araucaria Rulei*. *L. dendroideum*, the Ground Pine, is also a fine kind and not very difficult to manage. The numerous family of Saxifrages, being essentially "true mountaineers" are, of course, largely represented. Confining my enumeration to the choicest, I noticed several well established examples of the beautiful *S. florulenta*, which is not only one of the rarest but also one of the most difficult to manage—one that has for several years been a puzzle for some of the most skillful cultivators. It is grown in well-drained fissures firmly wedged between the rocks. Of the crustaceous section there are myriads of forms and varieties; in fact, too many to particularise. The rarest which I saw were the pigmy *S. diapensoides*, forming dense, hard, cushion-like masses; the Lichen-like *S.*

squarrosa, fine tufts of *S. valdensis*, *aretioides*, *Frederici-Augusti*, *cæsia*, &c., and grand masses of that most beautiful of all the spring flowering kinds, *S. Burseriana*.

The experiment of inuring reputedly half-hardy plants to the full vigour of a Yorkshire climate is practised largely and with a fair amount of success. Judging from the appearance of plants of *Philesia luxifolia*, a pretty Chilean shrub, which I saw here, it is much hardier than we have hitherto considered it to be, and the same may be said of the North American pitcher plants, *Darlingtonia californica*, *Sarracenia flava* and *rubra*, and even *S. psittacina* and *Dionæa muscipula*; the leaves of the latter fully exposed acquire a bright red colour, which is quite unattainable under the ordinary mode of treatment. The elegant little *Callixene polyphylla* will not succeed in open situations, though its near neighbour, *Luzuriaga radicans*, thrives admirably here as it also does in the open air at Kew. These are but a few of the rarities to be found here, and only a few indeed of the vast collection that has been accumulating here for many years from every available source. WILLIAM GOLDRING.

HARDY ORCHIDS.

THESE rank amongst the most quaint, the most interesting, and most beautiful of plants. Exotic Orchids are beyond the reach of many, but the hardy species can be grown and flowered well without artificial heat. Their treatment is somewhat different from that usually recommended for most of the exotic or Epiphytal species. I find that nearly all of them succeed in turfy fibrous loam from an old common where Heaths and Brackens flourish, adding to it an equal portion of fibrous peat. Some sorts of loam do not mix well with peat, and in that case I add silver sand, broken potsherds, and a little leaf-mould. I fill the pots half-full of drainage. It is best not to subject some species to a temperature lower than 32°; they certainly flower better and grow stronger if they are kept in a greenhouse in which New Holland plants succeed. One of the most useful for decorative purposes is *Orchis foliosa*. The flower stems of this are now pushing freely; just as they start to grow, and before many new roots are formed, they should be repotted. Turn the plants out of their pots and separate all the crowns carefully with the hands, preserving all the young roots intact. Place some Sphagnum Moss over the drainage, then a portion of the compost pressed in with the fingers and made level. On this distribute the roots evenly. I put one crown in a 5-in. pot, and from nine to twelve in an 11-in. one. Work more of the compost carefully amongst the crowns with the fingers, until the top of the growth is about $\frac{1}{2}$ in. below the surface of the soil. I then plant on the surface a few tufts of Moss, which is kept in a growing state all the season. The roots must not be allowed to become too dry, else the plants will suffer. Amongst hardy Cypripediums, *C. Calceolus*, a native of Britain, is one of the most interesting. It has been found wild in a few places in the north of England, but it is much more common in Switzerland. A gentleman writes to tell me that he found it abundantly in the Lanterbrumen Valley, where it grows in the woods; and the flowers are gathered in handfuls and placed in vases in the hotels. This variety grows most freely in pots. I had a single crown about six years ago, which I have divided this season and could count quite twenty stems; the treatment is in all respects the same as that recommended for *Orchis foliosa*. *C. pubescens*, a North American species, requires the same treatment in all respects. I find that it increases very rapidly, but not so fast as the other; a single crown has increased at the rate of one stem a year, but I have not yet been able to divide the plant. This is a very handsome species, second only to *C. spectabile*. This succeeds admirably in peat beds out-of-doors in a shady position; it will grow and flower pretty well exposed to the sun, but it does better with a little shade. I mix the peat with loam and sand for pot culture, and just keep the soil moist until the stems are 2 in. or 3 in. out of the ground, when water is applied more freely. The pretty little stemless species, *C. aculea*, succeeds well treated in the same way; and it ought to be stated that the Moss quite covers the surface of the soil with a green carpet some time before the plants are in flower. J. DOUGLAS.

Gladioli in Rose Beds.—Single bulbs of Gladioli planted in Rose beds in spring, in the open spaces, have borne three and four large spikes of fine flowers, and have made the beds look gay at a time when they would otherwise have been dull and comparatively bare. As the leaves of Gladioli are erect and occupy but little space, I find them to be one of the best subjects for introducing amongst Roses, as their many beautiful coloured spikes of bloom are highly ornamental; they also look extremely well when mingling with the large-leaved plants employed for producing a sub-tropical effect. — J. GROOM, *Linton*.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Dracæna Ehrenbergi.—In the Emperor's winter garden at Vienna this handsome plant was in flower a short time ago. The flower stem was 2 ft. in height, and much resembles that of a *Yucca* as regards the arrangement of the flowers, and the individual blooms much remind one of *Dracæna Draco* with very long leaves. There appears to be some diversity of opinion in reference to this plant whether it is to be a *Yucca* or a *Dracæna*. — L. KROPATSCH, *Laxenburg*.

Variegated Honeysuckle for Edging.—As a permanent hardy edging plant few will suit better than the dwarf golden-leaved *Lonicera* (*L. brachypoda aurea variegata*). It may be seen in one of the Vienna public gardens, where it is clipped to the height of about 10 in., forming a long strip in one of the parterres. — LOTIS KROPATSCH.

The St. John's-wort at Penrhyn Castle.—I always like Mr. William's notices in THE GARDEN, but in that about the St. John's-wort he does not seem to notice the fact that this plant, completely established over the surface of the ground, occasionally kills strong forest trees even, as was recently pointed out in THE GARDEN, and that it therefore requires to be used with great discrimination. — V.

Clintonia pulchella.—This pretty annual has done well this year as a bedding plant. We had several edgings of it, and during the summer months they were one mass of the finest blue that could be desired, in lieu of the rather too-much-seen blue *Lobelias*. — L. KROPATSCH.

Saxifraga Fortunei.—This is now in beauty in our rock-garden, the white flowers with the solid leaves having a very good effect. It is a plant which well deserves a snug corner to bring it forward, as otherwise placed the flowers are sometimes damaged by early frost. It is perfectly hardy. — G. F. WILSON, *Heatherbank, Weybridge Heath*.

Polygonum amplexicaule.—This is a most useful hardy flowering plant in autumn, when the majority of other plants are past their best, either for enlivening borders or for cutting purposes, for which it is well adapted, as its blossoms last a considerable time in that condition. Another recommendation is that it thrives where many other plants would starve. In the impoverished soil in the herbaceous ground at Kew it forms excellent clumps, and is very attractive just now. — W. G.

Lilium auratum Planted Out.—Beautiful as this well-known golden-rayed Lily of Japan is under glass, it is seldom one finds it in good condition out-of-doors; but that it is perfectly hardy and does succeed in some cases has been amply proved. A few days since I was surprised to see a beautiful spike of this fine Lily in full bloom, growing out of a *Rhododendron* bed, and evidently quite at home, as the blooms were equal in every respect to those grown under glass. This bulb must have been some years in its position, as it was quite overgrown. People desirous of adding a distinct and striking feature to their gardens cannot do better than plant good bulbs at once of any of the *Lilium* family, which they may be able to procure, in the open spaces of *Rhododendron* beds: they will, I am sure, be rewarded with a fine display next autumn, as the roots of both luxuriate under the same conditions, and the *Rhododendrons* are well suited to shelter the early growths of the Lilies. These in open, exposed beds are sorely affected by withering winds, which are much more injurious to them than severe frosts. — J. GROOM, *Linton*.

Native Plants on the Orme's Head.—I can assure "O. B." that the Ferns and Alpine plants referred to by me are to be found on the Orme's Head. I shall have great pleasure in giving him specimens of them, together with various other specimens, such as *Asperula odorata*, *Armeria maritima*, *Chrysocoma Linosyris*, *Cotoneaster vulgaris*, *Dianthus glaucus*, *Spiræa Filipendula*, *Veronica alpina repens*, *Lysimachia Numularia*, *Statice maritima*, *Orebis apifera*, *O. arachnites*, *O. conopsea*, *O. hircina*, *O. fusca*, and *O. pyramidalis*. These are but a few of the rare plants which may be found by any careful collector during the spring and autumn. — BOTANIST. [The foregoing cutting from the *Llandudno* paper last week is sent with the view of calling your attention to the statement that *Orchis hircina* is found on the Great Orme. Is this known to be a fact by our chief botanists? It is so extremely rare, and its habitats are so few that it would be pleasant to add this one to them. If I can find out who "Botanist" is I will try and ascertain whether he is right. In the meantime can any of your correspondents verify the statement? It is too late in the year to search. I cannot find the plant named in the only list I have of the botanical treasures of the Great Orme. — A. R., *North Wales*.

THE FRUIT GARDEN.

SEASONABLE NOTES REGARDING FRUIT.

LOOKING at the immature condition of the wood of all fruit trees, more sunshine is sadly needed, as nothing tends to consolidate and harden the shoots like the solar rays; for, do what one will by way of thinning and stopping, it is impossible, without such help, to ensure ripeness, or get the buds developed before the frost takes off the leaves, which are now so full of sap as to be very susceptible to its influence. Much, however, may be done in the case of Peaches and Nectarines by going over them at once and pruning out all the growth not required, as, by so treating them, light and air will be freely admitted, and the strength of the tree concentrated in the shoots left, instead of being wasted on wood that has to be cut away in the spring. If this autumn thinning were more practised it would result in a great gain, especially with the above-mentioned trees, which, from having to be trained to the face of walls, forces the foliage to over-lap and shade the branches in such a way that the sun never reaches a large portion till they become bare in the winter. To hurry the leaves off, as some do, with a view of letting in light, is a great mistake, as the buds require their assistance till they are cast off from them naturally, and, rather than remove one from a shoot that has to be laid in, it is much better to go thoroughly over the trees and take out what wood can be spared, and leave the other intact. Not only does this thinning hold good with those on walls, but it is even of greater importance with those in houses, and it is a good plan with these to go at once over them directly the fruit is gathered, and prune from them every shoot that will not be wanted for bearing or furnishing the trellis. To get the wood of indoor trees thoroughly ripe and brown, the atmosphere should now be kept dry and plenty of air on the ventilators at all times, which will help materially in dispelling the watery juices which the wood and leaves contain, and harden the tissues.

Vines from which Grapes are cut will require similar treatment, and if a little fire-heat is given by day, in the absence of the sun, they will be all the better for its assistance, as it should be borne in mind a satisfactory crop depends almost entirely on the condition of the present year's wood, for if that is soft and pithy the bunches next summer will be few and far between, and the chances are that instead of the berries finishing off properly numbers of them will shank. To aid those now ripening, fire-heat must be applied by night for another month at least, as, although they may be coloured fairly well, the juices are not yet converted into saccharine matter, and, without this change, Grapes are inferior in quality, and will not hang long on the Vines. In applying artificial heat, air must not be forgotten at the same time, but just a "crack" kept on back and front so as to let out any damp that may arise and keep the atmosphere in motion. If this is not done the moisture that naturally arises condenses on the berries, and not only spoils their bloom but causes mould and rot, and to prevent the spread of this the bunches should be looked over occasionally, and any berries showing symptoms of decay clipped out.

The lateness of the season will throw fruit gathering far into the autumn, as there are very few even of the earlier sorts of Pears and Apples yet ready, and it will require much watchfulness, and an acquaintance with the different varieties to know when to pick. In nine cases out of ten these fruits are plucked too soon, and the result is they shrivel and never attain to that degree of excellence they otherwise would. As a rule, the longer each kind hangs on the tree the better it is, and in no case should they be hurried off, unless frost of sufficient severity to injure them is apprehended; and then, of course, of two evils there is nothing for it but to choose the least, and at once get them from the trees. When ripe enough for gathering, all sorts begin to drop, which is a sure sign they are ready, that is, if they are fair samples of the crop that falls, as specked or maggot-eaten fruit are often tumbling, and are therefore no guide as to the maturity of the others. A good index of this in Pears is when, if turned gently upwards, they will leave their hold at the joint at the end of the footstalk, and if they do not separate freely they are not mature. All late-keeping sorts are always the last ready for picking, and should be left out as long as they will fairly hang on the trees.

In storing fruit of Apples and Pears it is a great mistake to lay them on straw, sawdust, or anything of that kind, as is frequently done, for however sweet those materials may be at the time of using, they are sure to become fusty afterwards from damp and the closeness of the room, and in the end impart an unpleasant flavour. Clean bare shelves made with boards are all that is needed, and on these the fruit should be laid singly, handling it when doing so, and also at the time of gathering it, carefully, for a bruise, however slight, is sure to lead to decay.

In places where the soil is stiff and wet, and the trees grow gross and strong, it is absolutely necessary every other year or so to adopt corrective measures to restrain them; for however well they may be attended to during the summer by way of stopping and pinching in the shoots, they will run riot, and especially in seasons like the present, with the air always saturated with moisture. Root pruning is the remedy for this excess of vigour, but the end of the month will be quite time enough to commence operations, as to interfere with trees now that are clothed with fresh green leaves would cause the wood to shrivel and the bark to contract, a condition of things to be avoided, as tending to throw the plants out of health. If the trees to be treated happen to be of large size, the safest and best way is to only do one side now and leave the other for next year, as to sever all the large roots around would cause too great a check, and defeat the object in view. Root pruning as generally conducted is a very barbarous proceeding, as the greater portion of workmen cut and dash with their spades at everything that comes in their way, regardless of the effect such a proceeding may have on the plant. Battered roots are like battered limbs; they take a long time to heal, and therefore too much care cannot be exercised in dealing with them, as the amputation they undergo should be of a surgical kind; the cut should be made with a sharp instrument, be it chisel or knife, for when the root is so severed it soon calluses over and emits a host of young feeders. It is the formation of these and the work they carry out that renders a tree fruitful, as they produce the flower buds, and the large or gourmand roots the wood or strong shoots, that are too gross to be fertile. All the smaller ones that have plenty of fibres on them should therefore be preserved with care, and this can only be done by opening out a wide trench and working the soil away from amongst them with a fork so as to lay all bare, when the operator can see what he is about and carry out his designs properly. If the big roots strike down, as is invariably the case, they should be lifted and laid straight out, or nearly so, and have some fresh turfy loam scattered over them with a little sharp sand as well, which will keep them clean and healthy and encourage fresh feeders. Small trees may be dug entirely round with perfect safety, but not closer than 2 ft. or so, and any of large size not nearer than a yard, as otherwise there is a risk of crippling them, especially if they have never been root-pruned before. When the work is done it is advisable to give a good mulching of half-rotten manure, which keeps the soil at a uniform degree of heat and moisture, a state that is highly favourable to the well-being of the tree.

In the other department of the hardy fruit garden the chief thing just now to be attended to is Raspberries, the old canes of which should all be cut away close down to the ground so as to admit full light and air to the young ones. These again, if left thick, may be reduced to from three to five, according to their strength and the distance at which the stools are apart, but there is nothing gained in leaving them thick as they only choke each other up in the spring and send forth a lot of weak branches that produce small inferior fruit.

S. D.

ROOT PRUNING.

I WAS pleased to see (p. 329) that "J. S. W." gets crops in exact proportion to the amount of "root pruning" which he does periodically; we have, therefore, only to keep the spade annually at work under the trees to render us independent of foreign fruit. I think I stated plainly (p. 316) that uprooting, except as a final end to the tree, was not practised hereabouts, and it was not likely that I should personally put into practice a system which I condemn in theory. I am sure that many will endorse the opinion of Mr. Coleman, who, in writing about Peach culture at Floors (p. 329), describes root pruning as a "necessary evil" that might, in most cases, be remedied by giving the branches free room to extend, and by circumscribing the root space so that they could not again descend into the cold substratum, or extend further than was found necessary; as I think the strongest advocates of root pruning will allow that its benefits are only temporary, and that pretty constant repetition is wanted to keep the trees fruitful. "J. S. W." seems to think the climate of Kent all that can be desired, but I am sure that what is applicable to this part of the country is equally, and even with greater force, applicable to the majority of English counties, as the light, warm soils of the eastern and western districts are far better suited to the early production and maturation of the bearing wood of fruit trees than much of the hard, stiff land devoted to fruit culture in Kent. If I made any exception as regards fruits that do sometimes need exceptional means to render them fruitful, it would be Pears; but even these, when allowed room for extension, as when grown on high buildings or exceptionally high garden walls, are just as prolific in proportion to the space allowed as "J. S. W.'s" restricted trees are when frequently operated on at the root. What I object to is the indiscriminate advocacy of root pruning in the case of trees with a mop-like growth of roots, as I am sure that if they are in a

condition to be moved without any check, they do not require to be moved at all; for although a tree may bear a light crop the year after the removal, it is only from established trees we can ever hope to get fruit as abundant as it ought to be. If root pruning helped them to brave our extraordinary seasons there would be some good in it, but of late years they need all the roots they can make, and superabundant vigour, thanks to dwarfing-stocks and double-grafting, is not much to be dreaded. "J. S. W." says his idea of fruit culture in Kent is that it is rather loose; but allow me to remark that is the very point where they gain so great an advantage over those whose rigid adherence to fixed rules of pruning prohibits their ever getting much fruit for their pains. Nowhere in the kingdom are fruit trees and fruit bushes pruned closer than here (if they need it), as, for instance, Nuts and Currants, while other fruits are allowed such latitude as is found to produce most fruitful trees; the object is fine fruit, not methodically-trained trees, and, except in very adverse seasons, a rich harvest is the result.

J. GROOM,

Linton.

"J. S. W." (p. 329) admits that "root pruning is useful in some cases," but I think he ought to have specified the "cases" in which it is useful; we should have then been better able to draw our own conclusions. I know that many parts of Kent have a deep rich soil, and what is most important, too, thorough natural drainage. I am a market gardener, who some years ago grew fruit for the markets—fruit which, for appearance and quality, was said to be superior to any in the kingdom. Mulching and top-dressing of course I agree with, but may I add that mulching a Peach tree against a wall is a very different thing from mulching an Apple or Pear tree in an open quarter. Possibly the border in which the Peach tree was planted was cropped with vegetables, and that working the surface soil over some 10 in. or 12 in. deep destroyed all the surface roots, and that consequently after the mulching the roots were encouraged to the surface; for I have found that roots will seek nourishment if it is within their reach, just as branches will seek light and air if it is possible for them to push into it, or rather out to it. Now the thought has struck me that in the case of a border exposed to the sun as a Peach border would be, and partly decayed manure used, would not this partly decayed manure hold very much of the water in suspense to evaporate into the air that ought to have gone to the roots? But I have said that mulching differed as regards its effects in an orchard or open quarter; let me therefore explain. Suppose the trees to be bushes, pyramids, or standards; the heads of these intercept the sunshine that would otherwise reach the ground; and although the same description of manure was used both on borders and in open situations, it would, of course, only hold the same proportion of moisture, which would not be evaporated on the border as on open exposures, but be carried into the soil beneath by the rain. Now with market gardeners the object is to get quality as well as quantity; indeed, quality is to be preferred, for when fruit of inferior quality would not sell at any price, that of superior quality would at a remunerative price, and so much is this the case that a tree under ordinary treatment (that is, one the roots of which have had no attention), would produce say 6s. or 8s. worth of fruit; whereas one whose roots were examined and well cared for by supplying them with nourishment at a distance easy to reach, would produce from 20s. to 30s. worth of fruit. If Mr. Groom had thought it worth his while to take up a tree and examine its roots, he would have found a wonderful correspondence between roots and branches. I remember many years ago being particularly struck with this. It was a Pear tree which produced long, weak, wiry branches, on which there was a great distance between the buds; and upon examining the roots I found them to be very similar—long, thin, lean, and fiberless; and I think any one on examining a tree or an undergrowth of large trees will find similar results. In the first case it is poverty of soil, and in the latter the want of light and air; but there is most assuredly a similarity between root and branch. May I say this has taught me a lesson not to be forgotten.

L.

October Peaches.—In most localities all the Peaches may be so characterised this season; few or none have ripened till October, not a few Peaches and Nectarines can hardly be ripe till November, if at all; while as for the true October Peaches, such as the Late Admirable, &c., they will not ripen at all. It is something quite unique in our experience to have been gathering Noblesse, Royal George, Violette Hâtive, Barrington, and even Rivers's Early York Peaches in October. We gathered very fine fruit of these and other sorts to-day (October 10th), and Nectarines are even later than Peaches. Growing side by side, this is singular. Violette Hâtive, Pine-apple, Hardwicke, and Pitmaston Orange are partly gathered, but the Elruge is still hard, as well as several other varieties. The rains seem to have suited Peach and Nectarine trees far better than

Apricots; though severely blighted in the spring, they have quite recovered, and are full of young and vigorous wood. But will it ripen? It seems extremely doubtful; and if not, and a severe winter sets in, such as is almost sure to follow on the heels of such a short summer, next year's crop is likely to be worse than this. Every possible means should be used to ripen the wood; chief among them is the removal of all superfluous shoots and leaves, and the exposure of those left to the full influence of light and air. In cases of gross growth the roots might also be pruned at once. If possible, too, some means, such as boards, tiles, or tarpauling, should be employed to shoot all the water off the borders. By thus cutting off the supply of water at the roots, the wood would be to some extent relieved of much of its gross sap, and as it were starved into maturity.—D. T. FISH.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Raspberry Culture.—I noticed at page 517 a note from "Cambrian" on the desirability of clearing away old Raspberry canes and getting the young ones for next season's bearing tied into place. This I have practised for many years with the very best results, so that I can bear testimony to the soundness of the practice.—KITCHENER.

Warner's King Apple.—This is becoming a favourite with market growers, and certainly it is a very useful fruit. Solid, firm-fleshed Apples fetch a higher price in the market than light, hollow-centred sorts, most Apples being now sold by weight. Such sorts as Lord Suffield and Cellini, planted largely a few years back, are already being discarded. Amongst early kinds the old Keswick is about the most prolific and largely grown, as when gathered as early as possible it is a sort that amply repays good cultivation. But Warner's King is one of the Apples of the future for main crops.—J. GROOM, Linton.

Castle Kennedy Fig.—This variety grows exceedingly well on a south wall here, and is never protected in winter. I have gathered the finest fruit from it this season that I have yet seen, six of which weighed 2½ lb.; and some of the fruits measured were between 9 in. and 10 in. in circumference and 5 in. in length.—RICHARD NISBET, Aswarby Park Gardens.

Peach Training on the Extension System.—The encouraging example of the extension system of training the Peach at Floors Castle (p. 329) should abate the prejudices still entertained by not a few against the system. We should like to hear of a single instance of a house, 45 ft. long, being filled in nine years or even twice that time by one tree trained on the restrictive system. The extension system has been persistently advocated in THE GARDEN almost exclusively since its commencement, and we now hear of a good many adopting it. Some five years ago or more I stated that a single Peach tree under glass would cover 600 sq. ft. of surface or more in ten years, and this it would appear has nearly been accomplished at Floors. Of course most cultivators are prevented from giving so much space to their trees from want of room, and because more than one variety is usually wanted in a division. It is exactly nine years this autumn since I wrote to your contemporary, *The Gardener*, recommending the extension system more generally, and giving the results in the shape of growth and fruit obtained here from trees planted a few years previously, and the subject was taken up by another writer at the time, who predicted the most disastrous results to the plan "after a few years"; but these prophecies have not been fulfilled in any single instance with which I am acquainted. The theory of the objectors is that the trees run out and get bare at the bottom at an early age, an altogether erroneous idea as any one may prove for himself.—J. S. W.

Orchard Houses.—Mr. Rivers has sent us fruits of the Tardive d'Orleans Apricot ripened under glass—just a month later this year than in ordinary seasons. Though good, they were not so juicy or well flavoured as usual, owing to the want of sunlight and heat. Along with the fruit in question came the following letter from a gardener in South Wales: "Wall fruit, this cold wet summer, has proved to be a complete failure here. I think it my duty, therefore, to strongly recommend orchard houses and pot trees. We have now had nearly three years of failure out-of-doors with the wall fruits, and they have not paid for the labour bestowed on them. Owing to our situation being low, we get dreadful fogs and white frosts. My idea is that walls would pay better furnished with Plums and Pears. I have two orchard houses filled with trees in pots, and trees on the back wall in my lean-to house, which is slightly heated; but my span-roofed one is a cool house. In both of these houses I always get a good crop. The trees have only 3 ft. of ground each on which to stand, and yet the Peach and Nectarine

trees this year in both houses average five dozen fruit each, large and small. On Plums and Cherries there are a great many more. Half-a-hundred trees can be grown in a medium-sized house. As the fruit from one tree is gathered, I place it out-of-doors and give the others a little more room. I have a Plum tree in a 15-in. pot which ripened 154 fine fruit. I have Pitmaston Duchess Pears weighing 1½ lb. each. Three Cherry trees carried 76 dozen. Pot trees in orchard houses are very profitable, and when in bloom they are a grand sight. The Peach called Prince of Wales has borne 89 very fine fruit, and is now in a 15-in. pot. The tree is twelve years old. Souvenir du Congres, though a small tree, is bearing twenty Pears; it is in a 12-in. pot; Durondeau, in a 13-in. pot, twenty-four Pears. Coe's Golden Drop Plum, in a 13-in. pot, has borne seven dozen very large fruit. These are not the only ones I have like this; I have more than half-a-hundred quite as good."

THE KITCHEN GARDEN.

NOTES RESPECTING VEGETABLES.

IN the kitchen garden late Cauliflowers will now be turning in, to protect which from frost it is a good plan to bend a few of the outer leaves over the heart, as they are exceedingly tender and soon suffer injury from frost. All Potatoes are now best out of the ground, but should not be pitted if they can possibly be kept in a dry airy shed or cellar, as the flavour when stored in the first-named way is always earthy and disagreeable, and if allowed to remain long the tubers begin to sprout, which further deteriorates their quality. Those required for seed keep best in the light, where they should be laid thin and have all the air that can be given, as the point with them is to retard their sprouting to as late a period as possible. In the culture of Celery the general course is to earth up as growth proceeds; but I am convinced, from repeated trials I have made, that it is bad practice, as, should it require water late in the autumn, as it always does, except in a dripping season like the present, it cannot be given in sufficient quantity to reach the roots without washing the soil into the heart. Rather than earth up so early, it is far better to tie each stick around with a piece of matting just to keep the leaves close till the time comes for blanching, when the earth can quickly be packed to the sides of the row.

Among common vegetables one of the greatest delicacies in spring are young Cabbages, and to have these tender, succulent, and good, the ground in which they are to be planted must be heavily manured and dug to a good depth that they may have a good root-run. To get them to turn in early, it is high time they were put out, as after October they move slowly, and do not get hold of the soil so readily. For a spring Lettuce there are none to equal the Bath Brown Cos, a first planting of which should at once be made close up to the foot of a south wall, where, let the winter be what it will, they are sure to pull through, and afford fine, full, crisp hearts long before any can be obtained from the borders farther out in the open. A planting made at the same time in a warm, sheltered spot will yield a succession and keep up a supply till the spring sown come in. As to young Cauliflowers, I like to have the first batch potted in rich, light soil, and wintered close up to the glass in cold frames, where they can have plenty of air night and day to keep them sturdy and strong, as, treated in this way they may be transferred to the open quarters by-and-by without check, which generally causes so many others managed in the ordinary way to turn in prematurely. S. D.

Land Watercresses.—Growing Watercresses on land is by no means a difficult matter, and with ordinary care a good supply can be had for a considerable portion of the year. Mr. W. Bunn, gardener to E. M. Nelson, Esq., Hanger Hill House, Ealing, utilises every year a cool, moist north border under a wall as a Watercress bed, and gets a good and lasting supply of this wholesome salad. When forming a new bed a piece of ground under the north wall is well manured and dug and got into good working order, and in early spring the seed is sown either in drills or broadcast and covered with some fine soil. As soon as warm weather sets in the seed quickly germinates, and if the bed be kept moist during warm and drying weather, a crop of Watercresses can be had early in July, unless the season be a late one. The Watercress, being such a moisture-loving plant, it is absolutely necessary to keep the bed watered every morning in dry weather. When autumn comes on, Mr. Bunn places hand-lights over the plants and secures a crop of Cress all through the winter. He states that he has had a bed which lasted ten years, owing to the plants seeding themselves every year. As a matter of course, some top-dressing in spring will be found to be of great advantage. Many a piece of ground on the

north side of a wall or building could be utilised in this manner. The Cresses grown in this way are as sweet and crisp as those grown in an ordinary water bed.—R. D.

The Champion Potato.—Those who planted the Champion Potato this year will, I feel sure, not be sorry for so doing. Out of all our varieties of Potatoes—namely, Old Ashleaf, Fortyfold, Dons, Regents, Victorias, Rocks, and Champions—the only one not diseased is the Champion. I planted double the quantity this year, and without manure. I lifted six shaws recently, and I find they are a first-rate crop, eight and twelve Potatoes being attached to a shaw, which would be from 40 tons to 50 tons to the acre—anything but a poor cropper, I consider. I do not know anything of Magnum Bonum, but this I do know, that the Champion is a first-rate late Potato, of good and, I may say, excellent quality, and disease-resisting. I spoke favourably of it last year, and I do so again, in the hope that most people who want winter and spring Potatoes will give it a trial, and I am sure they will not be disappointed. We were eating Champions in July this year, eight months after they were lifted, and they were certainly better than young Potatoes that we were getting then from the outside. I think its immunity from disease is due to its lateness and to its strong woody stem. I do not see the least symptom of disease in any of the three quarters where they are planted, while, as I have said, all the others were, and are, badly diseased.—HENRY KNIGHT, *Floors*.

Ne Plus Ultra Pea.—Mr. Groom has given (p. 328) a word of praise respecting this Pea for autumn use. I, too, must give it a good word, for it is most useful to me now; but I must add that I have two long rows of Peas in full bearing, one is Cuiverwell's Prolific Marrow, the other Ne Plus Ultra. The former is a much larger Pea than the latter, fine in flavour, and is regularly giving us two dishes for one of Ne Plus Ultra.—READER.

The Chatsworth Tomato.—I saw a Tomato at Clumber the other day bearing this name. It is of large size, and very handsome. Mr. Speed, who raised it, states that it is a seedling from Criterion, and that, while it is a strong grower, it is very early and remarkably free. In form the fruits resemble those of Hathaway's Excelsior, and they are of a deep bright red colour.—H.

French Asparagus.—Without question M. Godefroy-Lebeuf is correct in saying that all soils can be made to produce good Asparagus. All depends on treatment, except early cutting; that may and does vary from two to three weeks, even in places not many miles distant. With me, in the south-west of Dorset, a dish can generally be cut about April 1, and we aim at discontinuing cutting after the first week in June, just as the early Peas come in. I have two vegetable gardens consisting of entirely different soils; one friable, and hardly more than 10 in. before the spade reaches the white gravel, can be worked nearly at all times; the other, not 100 yards distant, has for soil strong clay; it is equally or in some seasons more productive than that on the light soil, but it requires good management and dry summers. Both these gardens produce good Asparagus, averaging from 2 in. to 3 in. or more in circumference at 3 in. from the tip, and amply supply us; what more can we desire? As to preparing the beds for winter, I cannot agree with forking up, unless under peculiar circumstances. I only cut off the ripe stalks and give a good dressing of rotten manure (from the late Vegetable Marrow bed), and dress also with plenty of common salt. Nothing, even in England, pays a market gardener better for growing than Asparagus, provided he resides near a large town.—EUGENE E. P. LEGGE, *Court House, Litton Cheney, Dorchester*.

Magnum Bonum Potato Diseased.—Since writing on this subject about a fortnight ago, the disease has made rapid progress in the haulm of this variety, and where it is worst there is no difficulty in finding diseased tubers—as many as three and four at a root, and some of them quite gone throughout. Where the stems are greenest they are, however, still free. The same thing has happened on other parts of the estate. Lately the weather has been fine and mild, but foggy. I see that "A. D." thinks I am wrong in attributing the freedom of Magnum Bonum from disease to its lateness, and says that Paterson's Victoria is as late and gets badly diseased. I have not grown the latter this year, but it is one of the freest from disease in this locality, and I think it has generally borne out that character. Of course, I admit there are differences in kinds, but I do not believe that Magnum Bonum will be found to bear out its character as a disease-resister when subjected to the same conditions as the others, and the results here seem likely to prove as much. I hope I shall be able to state a few weeks hence that it is still as free from disease as it is at present, but I have doubts. One statement of "A. D." surprises me very much. It appears he has got his crop of Magnum Bonum sometime since, and the foliage, we are told, "died long before the tubers were ripe"—rather a curious physiological circumstance. I never before heard of a Potato the haulm of which died long before the tubers were ripe unless it

was killed by disease of some kind, nor did I believe perfect maturation of the tubers could be accomplished without leaves. It is universally acknowledged that a ripe haulm indicates a ripe tuber, but *Magna Bonum* must be an exception if "A. D." is correct in his observations. All over this district *Magna Bonum* is the latest Potato in the fields and gardens, and "A. D." is very fortunate indeed that he can ripen it by about the end of August, as his statements seem to imply.—J. S. W.

Asparagus Culture in America.—Mr. A. Van Sicklen, of Jamaica, Long Island, is one of the best growers of Asparagus for our New York market. He plants very wide, 6 ft. by 4 ft., for field culture; the first year after planting the Asparagus he plants a crop of Cabbage between the 6-ft. lines. The object of the wide planting is to allow the yearly use of manure to the roots, which he applies early in spring by ploughing as close as practicable to the roots on each side, then applying 2 in. or 3 in. of well-rotted manure on or close to the root, then again levelling in the furrows by plough or cultivator; in this way the crop produced is enormous, and the bed so worked would be quite as good at the end of twenty years as at four. This, though a little more labour than manning on the surface, gives the full benefit of the manure to the roots.—PETER HENDERSON, in *Gardener's Monthly*.

ROOTS AND "YARBS" IN NORTH CAROLINA.

THE following extracts from a letter from Prof. Asa Gray to the *American Agriculturist* will give some idea of a little known region, and a peculiar local industry, viz., that of the Root and Herb business as carried on in the mountain districts of Carolina. Our botanical journey took us to the head-quarters of the business, and through the regions where most of the collecting is done. Being ourselves members of the herb-confraternity, we were received with enthusiasm, and shown all the operations. "Sang," i.e., Ginseng, the original foundation of the trade, has been collected ever since the earliest settlement of the country, and is by this time pretty well rooted out from the more accessible districts; but it is still brought in, and brings 75 or 80 cents a pound. When I was first in these mountains, between 35 and 40 years ago, this, and Angelico-root were the only things which were gathered for market. Now the price-list which you will find posted at almost every road-side store, enumerates over 200 articles. Some of them are cultivated plants, such as summer Savory, Southernwood, Pæony-flowers, Water-melon-seed, and leaves of the Poppy and garden Lettuce. But most are of wild herbs, or the bark or berries of trees, or in some cases blossoms. Elder flowers for instance, are a prime article. The collecting is done by women and children—it could be done only by cheap labour—and the articles, when dried, are taken to the country store, usually to the nearest county seat, and exchanged for "store goods," very little money passing. Almost every day we would meet women on horseback, with a bundle of the more bulky herbs on the off side, commonly wrapped in a sheet or blanket, and another on the pommel, and a basket in one hand. With the proceeds they buy most of the clothing that is not made at home (for happily the wheel and the loom hold their place in almost every house), perhaps some sugar, and their small finery. But "tree-sugar" is made for home consumption, and serves for the Coffee (Tea is unknown, at one place, where our Tea was pronounced "not bad to take," we were requested to tell them what they should call for if they ever got any at the store); and the best of honey abounds. In these mountains milk and honey literally flow without price. At least we could never get the people to fix any.

From the country stores the roots and herbs pass to the larger dealers, and from these only would you get any idea of the magnitude of the business. You should see the herb-warehouse of Mr. Cowles at Gap Creek, in Ashe County, and the much larger one at Statesville, of the enterprising Wallace Brothers, under the charge of Professor Hyams, three of whose sons are in the business at different points, and one of them in McDowell County, where he was the fortunate discoverer of the long-lost *Shortia*. Bales upon bales of roots and herbs, compacted by a powerful screw press, accumulate in these warehouses, and pass on to the northern cities and ports. What becomes of them? Some are standard articles of the *Materia Medica*, such as Mandrake-root, from which *Podophyllin* is made. One day, while we were present, an order came to one of these establishments for ten tons of Mandrake to go to France. The larger number of articles go into patent medicines. You may form some idea of the demand for this purpose from two orders just received, one for an unlimited amount of Liver-leaf (*Hepatica*) and the other for two tons of Maiden-hair (*Adiantum*). Consider what a quantity of these in a dried state would go to a ton?

And now, if I begin to tell you anything about Azaleas, Laurels, Rhododendrons and Kalmias, there will be no end. We were

just in the season for these in all their glory, having timed it accordingly. You may say there is no need to go to the mountains of North Carolina for these, but you will get new ideas if you do. Nowhere else can you see wooded hill-sides of the richest green break out into flame with *Azalea calendulacea*, and nowhere but in Rhoan can you see some miles of grassy mountain-top all ruddy and rosy with *Rhododendron catawbiense*. Now you can comfortably reach the top of Rhoan mountain in 36 hours from New York, and be in mountain air all the way after leaving Lynchburg, and on the mountain be most comfortably and cheaply housed and fed, at the Cleveland Hotel, at an elevation of a few hundred feet higher than the top of Mount Washington, and enjoy an air which is cool without bleakness, and views such as we have never elsewhere seen the like.

PLATE CCII.

ALLIUM PEDEMONTANUM.

Drawn by CONSTANCE PIERREPONT.

THIS is certainly the most beautiful Alpine plant which it has been my good fortune to see in a wild state. The day on which it was found I well remember leaving a small hotel in Piedmont, about six o'clock in the morning, accompanied by an Italian. Hour after hour, and mile after mile, we traversed in search of Alpine treasures, but up to four o'clock in the afternoon with but little success; when, returning home by another route, we suddenly came upon a steep shelving bank of *débris*, which was dotted over with tufts of this very gay plant then in full flower. Its large drooping heads of reddish-purple blossoms, waving in the wind under a glorious setting sun, was a sight long to be remembered. The plant is tufted or crowded at the base, with stout fleshy root-stems, which are, in fact, the elongations of the bulbs. These are coated with densely matted fibre, with from four to six narrow grass-like leaves. From the centre of the foliage springs a straw-like acutely-angled scape, 4 in. to 9 in. high, bearing at its summit a compact head, composed of from four to nine drooping bell-shaped flowers, about $\frac{1}{4}$ in. long. It thrives well in any well-drained garden soil, and will prove to be an invaluable plant either for the mixed herbaceous border or for pot culture. Its beauty is, however, greatly enhanced by its being placed in such a position on rockwork that the flowers are level with, or a trifle above the eye, in order to be seen from below instead of looking down upon them. There are two other species closely allied to the above; *A. narcissiflorum* is exactly like *A. pedemontanum*, but is devoid of the fibrous coating round the root. The other one is *A. insubricum* (Boiss); it has larger flowers and broader leaves; the flowers, however, are much duller in colour. It has been passing under the erroneous name of *A. grandiflorum*.

R. POTTER.

[The specimen from which our plate was prepared was supplied by Messrs. Backhouse of York.]

***Tigridia grandiflora*.**—What a glorious autumn hardy flowering bulb this is, and, singularly enough, although old-fashioned, it is comparatively but little grown. A fine boxful of it was sent by Mr. Cannell, of Swanley, the other day to our local show, where the gorgeous colouring which the blooms possessed caused exclamations of wonder as to what they could be; they certainly looked more like the blossoms of some brilliant Orchid or inhabitant of our stoves than the produce of an open air plant that had braved the storms and floods of 1879.—J. GROOM, *Linton*.

Silver-edged Grasses.—Some inquiries of late having been made about silver-edged Grasses, I may observe that I never met with any that looked so well as *Dactylis glomerata variegata*, by some called *D. elegans*, I believe; and Mr. Williams may be a little amused when I tell him that I first met with it in a garden a very short distance from Ormskirk, about the year 1857, and brought it to the south of England some years before it was commonly cultivated there. I subsequently obtained *Festuca glauca*, and also one called *Stipa pennata*, both so near alike that I could not discover any difference between them; consequently I discarded one. Both had a sort of grey foliage rather than silvery-white, like the *Dactylis* mentioned above; but I confess to losing the latter more than once, the dry summer of 1861 and afterwards being fatal to it. It does not appear to have become much grown, except in specially rainy districts. I have never, however, seen any silvery form of Grass to equal it in beauty when well grown. But I do not despise the old Ribbon Grass, or the Gardeners' Garter, which is still well worth attention; it is not particular what kind of a site is allotted to it, and a few plants in pots in early spring are well worth growing.—AN OLD GARDENER.

ALLIUM PEDEMONTANUM (WILLD.)

GARDENING FOR THE WEEK.

Flower Garden.

At present by far the most interesting portion of the flower garden is the mixed, or what is generally termed the herbaceous borders; for, though many kinds of flowers are over and beginning to look weedy, others, such as Michaelmas Daisies, herbaceous Phloxes, Anemone japonica, and Stocks, are likely to keep up a succession till severe frost destroys them; meanwhile the bestowal of a little extra attention in the removal of weeds, decayed flowers, and fallen leaves, will add to the fuller enjoyment of such flowers. As soon as the leaves are off the trees, and there is no further likelihood of litter on that account, the borders may be lightly forked over, and any plants the stock of which it is desired to increase may then be divided. Most kinds will bear division with impunity; at the same time it is well to remember that, as a rule, established plants flower most profusely; therefore, except for the purpose of increasing the stock, or preventing encroachments, such division is undesirable except at rare intervals. The wet season seems to have suited this class of plants, so that many have much exceeded their ordinary growth, hence this will be a good season for division. Plants on rockwork have also done uncommonly well, and any re-arrangement or propagation by division may also now be carried out in their case. Sub-tropical plants that are intended to be preserved ought now to be housed. At this place, having no accommodation for wintering large plants of this character, we depend for our supply almost solely on seedlings raised in January and February, and therefore the plants are left in the beds till the frost has done its worst. Up to last winter Cannas wintered safely in the beds in which they grew with the protection of Bracken, but all were then killed; they will therefore this season be lifted and wintered in a shed, from which frost can be excluded. Abutilons are worthy of being housed early, as if placed in an intermediate house they soon re-establish themselves, and are invaluable for the production of flowers at a season when they are scarcest. Dracænas and Palms are also valuable for indoor winter decoration, and these too should be taken up early. Though we have not yet experienced any sharp frost, it will not be safe to risk out any longer tender bedding plants which are intended to be preserved. All the fine-foliated Pelargoniums are most susceptible of injury, and if at all frost bitten wintering them safely is a difficult matter. All other bedding plants which have been propagated for stock ought now to be housed, but they should have as much ventilation as it is possible to give them whenever the weather is favourable. Damp is their greatest enemy, and as the careless use of the water-pot tends to engender such damp, quite as much as atmospheric conditions, this should be avoided. There is now such a wealth of plants suitable for filling beds in winter, that empty or bare beds ought not to be thought of; a list of some plants most suitable for this purpose was given in a former note. Our hope is that very shortly summer bedding will be so largely composed of hardy plants that but little supplementary planting will be required for the winter season. If this were the case the strongest objection that is with good reason advanced by the opponents of summer bedding, viz., its transitory character, would be done away with. A few more seasons like the one through which we have just passed, and our wits would be so exercised as regards the outlook for hardy summer bedding plants that all we required would soon be obtained.—W. W.

Auriculas.—Hardy Alpine Auriculas make very beautiful spring flowering plants in the open borders. They may now be planted in an open position, but they had better not be where the sun shines too much upon them. It would not do much harm at present, nor in early spring, but as the plants are intended to remain all through the summer months, it is at that season when the sun's rays have an injurious effect upon them. The soil should be good and well-trenched, placing some well rotted manure from 6 in. to 1 ft. below the surface. In planting it is very desirable to place some good fresh maiden loam round the roots if it can be obtained; if not, the plants will succeed without it. Many complain that such plants as Auriculas disappear from the flower borders during summer; the heat and drought are blamed for this disappearance. No doubt Auriculas do not like to be exposed to a flood of sunshine during summer, but they will live and thrive through this rather than be suffocated by Verbenas or zonal Pelargoniums, which cause not only the death of these beautiful flowers but of many others besides of similar character. Weakly-growing herbaceous plants used to thrive well in borders, and they do so now when they are protected from the devouring influences of bedding plants mixed amongst them in summer.

Carnations and Picotees.—Continue to pot off rooted layers of these as soon as they are ready, and if but few roots have been made the pots should be kept in a rather close frame, and be shaded from the sun until they are established. They do not seem

to have rooted very freely this season. Yellow-ground Picotees or yellow-self Cloves or Carnations are not so much grown as they should be. Chromatella is the name of a very beautiful pale yellow variety exhibited by Mr. Ware this year, and from the same collection was introduced a very pretty variety named Sulphur King, a bright yellow-coloured kind; then came King of the Yellows (Abercrombie), a very beautiful yellow self. All these should be grown in the most select collections. The edged flowers, or what may be termed yellow-ground Picotees, are worthily represented by the variety named Prince of Orange (Perkins); now we have a numerous progeny from this fine variety. They are all hardy plants, and are also well adapted to be grown in pots and gently forced in spring. Those intending to purchase Carnations and Picotees should now do so; they move best at this season just as they are taken from the parent plants.

Hollyhocks.—Late flowering plants of these have had a good time of it. The weather has been for the last week or two quite delightful after such a trying summer. The barometer is higher and steadier than it has been for many weeks. Seedling plants should now be put out without delay, so that they may become established before the winter. Not only Hollyhocks, but also many other hardy plants, often suffer from inclement winters, owing to their not being established before frost sets in. Much depends, too, upon the state of the ground, the surface of which should be kept loose and dry by being frequently stirred up with the hoe. A close, hard surface sometimes causes an unhealthy growth through the sourness of the soil. These remarks apply to all classes of hardy florist's flowers put out in the open ground.

Pansies.—Our hardy plants in pots increase almost too fast, but it is nearly impossible to resist the temptation of trying to grow a frameful under glass. Last season it was late before our plants were put out in the beds, and they did not do well; quite two-thirds of them were killed in winter by the frosts and wet combined. Had they been well established before winter probably not one would have been injured. We will grow one of each variety in pots, and probably the others will be placed in boxes and be kept under glass to be planted out in February or early in March as the weather may determine.

Polyanthuses.—These are much more attractive to insect pests than Auriculas, and a word of caution in respect to them may not be out of place. I had some choice varieties from the north this week with the remark that they had been attacked by red spider in summer, but that it was probably gone now. That, however, was not the case, the undersides of the leaves being quite alive with this pest. I dipped the leaves in strong soft soapy water and killed it. This I merely state as a warning to those who may see the leaves turning yellow. No doubt red spider is the cause; green fly is also very fond of the leaves, and it can also be destroyed in the same way as red spider. *Primula amœna* and its varieties must not be neglected at this season. Ours have just been repotted, turning the plants out of the pots and breaking them up into pieces; if a certain-sized pot is full of crowns, these, when broken up, will fill two pots of the same size. I use for these the same soil as that which is recommended for Auriculas, and place the pots in frames near the glass.—JAS. DOUGLAS.

Stove.

There are now many plants that annually go to rest through the winter, and that require gradually inducing to that condition. Amongst these are the last of the Achimenes, Gloxinias, Caladiums, and others of a like character. As with those that made their growth earliest in the season, and have gone to rest some weeks ago, these latest must be dried off by degrees, not subjecting the foliage to over-sudden destruction through the complete absence of moisture in the soil, or the roots are certain to suffer.

Anthurium Scherzerianum.—Where several examples of this plant are cultivated it may be had in flower over the greater portion of the year. The individual blooms may not be so appropriate for using in small combinations of cut flowers as some things, yet two or three with long stalks can with advantage be employed in large vases, where their lasting properties will be an advantage. In no way is the plant more useful than when grown in medium sized form, and placed about on the stages amongst other plants, especially Orchids, where its colour and general character contrast with those it is thus associated with. A lower temperature than it often is subjected to will result in stronger growth and larger flowers than when kept hotter. The coolest end of an intermediate house, where the temperature will not run above 50° in the night, just suits it, and if the plants are furnished with a full complement of healthy roots, they will be now in the height of their growth, and must be plentifully supplied with water. There are almost innumerable forms of this Anthurium, differing very much in the size of their flowers, but the best varieties are in this very much

influenced by the healthy condition of the roots, which, if through any cause happen to get deficient in quantity and active power, I have found it to take two or three years careful treatment to reinstate the plants in their wonted vigour. Plants that pushed up their flowers in the early part of the year, and which have now finished their growth, which may be easily seen by the matured state of the leaves with no disposition to produce more, should now receive considerably less water; but as it is in reality a swamp plant it must by no means ever be allowed even when at rest to have the material in which its roots are placed quite dry; but if more water than necessary is given now, when no growth is going on, the excess of moisture accelerates the decomposition of the material in which the roots are placed, a circumstance which should be avoided.

Eucharis.—Amongst large white flowers where a continuous supply is wanted, there are few, if any, that equal the *Eucharis*, especially the well-known *E. amazonica*. No matter how extensive the stock may be it is necessary to vary the treatment with portions of it, so as to ensure a successional supply of bloom, otherwise it is quite possible that, even with a moderate-size houseful of it the cultivator may find himself at times for a considerable period without so much as a single flower, whilst at other times there may be many more forthcoming than are needed. Though so easily managed that by alternate periods of rest and growth the plants can be induced to flower at any season of the year, yet I have found that by dividing the stock into three or four batches, which were each excited into growth and put to rest at given times, each lot of plants so treated in the course of two or three years got into a regular habit of coming on at the time when they were required. During winter the flowers are of most use, and if the portion of the stock that bloomed and made growth early in the season, and have been kept sufficiently dry with more air, so as to check further leaf production, are now put into a brisk heat, they will very soon begin to throw up flower stems. By similarly treating another portion, so as to induce rest for the next two months, they will by the close of the year be in a condition for forcing, the flowers they produce keeping up a supply till spring is well advanced. It is only by treating this plant systematically that its blooms can be had at the time wanted. Independent of the value of its flowers for cutting, the purpose for which it is most generally grown, where blooming plants are required to occupy small vases and similar contrivances, there are few plants so effective as single bulbs of this *Eucharis* grown in 6-in. pots; the four or five healthy leaves from which spring a single stem of flowers with which a well managed plant is furnished, have an effect so employed such as few other subjects are capable of producing. The flowers will keep on the plants in the temperature of an ordinary living room for ten or twelve days, and even when the weather is cold this *Eucharis* suffers less than most stove plants so treated. *E. candida*, yet comparatively scarce, may not turn out to be so manageable as *E. amazonica* as regards flowering at any time, but it is nevertheless a most desirable plant. Its smaller more elegant flowers are by many held in preference to those of *E. amazonica* for bouquets. Though impatient of too much sun during summer, from this time until spring both plants cannot be too much exposed to the light. They are especial favourites with mealy bug, and where that pest exists there is no remedy except keeping a watchful eye upon them, otherwise the bug gets down into the crowns of the plants, and on the undersides of the leaves, to an extent that in a short time so far injures the foliage as to much reduce the blooming capabilities of the plant.

Ardisias.—These, which are amongst the best of small berry-bearing plants, are, in many cases, late in getting the berries fully coloured this year, and in order to accelerate this they will require keeping in a little more warmth than would be necessary during ordinary seasons; but they must not be kept too hot, or frequently when submitted to a lower temperature the berries fall off prematurely. Plants raised from seed, or in spring from cuttings, must not be allowed to stay in the little pots which they occupy too long, as the best system of cultivation to follow with them is getting them up to a sufficient size without delay; for if they get into a stunted, slow-growing state they almost invariably lose their lower leaves, the effect of which is to make them so unsightly as to necessitate their being headed down. The tough, hard texture of their leaves is such as to guard them much better against the attacks of insects than many plants, yet nevertheless if affected with aphides whilst the foliage is young its free development is stopped. Healthy leaves are requisite for the satisfactory appearance of all plants, even in the case of those that are grown for their flowers; but with these *Ardisias*, as with all other subjects cultivated for their foliage and berries, it is doubly essential that the leaves should be perfect.

Francisceas.—*F. confertiflora*, the best of all the *Francisceas* as well as one of the finest of stove plants, requires to manage it well to be differently treated from most things, especially where it is wanted to stand in a cool house when in flower. Its exceptional treatment

is this, that whereas most plants needing heat require to be kept in the warm position in which their growth has been made until the flowers are set, this *Franciscea* should at once be moved out of heat as soon as the wood growth is completed, but before the flowers are distinctly visible, otherwise they are apt to fall off. A temperature of 45° through the winter will suit it best. *F. eximia* and *F. Lindeni* will succeed under the same treatment, but are not so liable to drop their flower buds, yet in their case it is better not to allow the buds to get too large before being placed in cooler quarters for the winter. All the above will succeed when kept in a brisk heat after the growth is made and the flowers set; but in this case they bloom much earlier, and the flowers, when open, are so soft as not to admit of the plants being used for decorative purposes in green-houses and conservatories. *F. calycina*, which, like the foregoing, may be had in flower from late in the winter until the summer is far advanced, needs to be kept continuously in warmth, by which means, when in a strong healthy condition, it will generally bloom twice in the year. There is one reason why these *Francisceas* with their beautiful soft, purple-tinted flowers are not more generally grown, and that is where mealy bug exists it is a difficult matter to keep it under without injuring the plants, as their foliage does not bear the rough usage too often practised in clearing them of vermin.

Forcing Pit.

Bouvardias.—The present treatment of these will require to be regulated by the time the flowers are required. So manageable are they that little difficulty is experienced in getting them into bloom whenever wanted. As a matter of course, the strongest plants, such as grown from cut-back stools which bloomed last year, will be the furthest advanced in growth and in the best condition for blooming first; they will bear as much heat as most things, and, where the plants are really strong, will furnish through the winter greater quantities of flowers in succession when submitted to a brisk heat than where treated to an intermediate temperature. Plants like these, in common with others that make some growth through the winter, will be benefited by the application of manure water at short intervals; not only will it assist the development of the first flowers, but also those which come later upon the after growth. A portion of the stock of *Poinsettias*, *Sericographis Ghiesbreghtii*, and *Plumbago rosea*, and *Eranthemums*, will now need removal to the forcing pit where a structure of this description is at command, and where not available room must be made in the stove, as a moderate heat is necessary to bring them in at the time required, as also to enable such plants as the *Poinsettias* to attain the full size which in many places is required. Although they will bloom with less heat than is usually present in a general stove, still they are never so fine under the cooler treatment. See that the whole stock of all these plants is perfectly free from insect pests of all kinds, for, with plants like these, that it is necessary to keep in warm quarters, insects, if present, increase apace; they also interfere with the flowering, and entail no end of labour to keep them down. In addition to the above, a portion of any others grown to flower during the winter should likewise be placed under the conditions of heat that will bring them on.—T. BAINES.

Hardy Fruit.

Notwithstanding our gloomy forebodings, the Apple and Pear crops hereabouts are turning out fairly well, the fine weather which we have recently had having wonderfully assisted the free swelling of the fruit. So much has this been the case that some few kinds of both Apples and Pears are as good as in former seasons, notably the following Pears—Pitmaston Duchess, Marie Louise, Duchess de Angoulême, Beurré Hardy, Brown Beurré, and Durandean. The following kinds of Apples are remarkably fine, viz., Ribston Pippin, Cellini, Keswick Codlin, Blenheim Orange, Warner's King, and Court Pendu Plat. I name these that intending planters may make note of them, seeing that they are so good in a season that has been so adverse to hardy fruit generally. Fruit gathering will soon be at an end, and the fruit room will require careful management till all the fruit has undergone the "sweating" process, which invariably takes place during the first week or two after storing. Keep the ventilators open night and day (unless the weather is excessively wet), and as soon as the fruit seems dry, and has got thoroughly inured to the temperature of the room, then ventilate for about a couple of hours every fine day, and close up during wet, fog, and frost. The fruit should be stored as thinly as space will allow, both to ensure its better keeping and to permit its being examined for the purpose of removing any that have begun to decay. Any specimens that is desired to keep for exhibition or other special purposes, should, when thoroughly dry, be wrapped up separately in tissue paper, and placed in drawers or boxes with the view of excluding atmospheric influences as much as possible. The weather is now most favourable for planting, root pruning and top-dressing, to which reference was

made the other day (p. 311), and the sooner such work can be done the more successful it will be. There is also another reason why this year it should be done early, and that is that a moderate disturbance of the roots will probably have a beneficial effect on the ripening of the wood, which in many cases is unusually immature; and a check thus given will conduce to maturity without danger of the wood shrivelling, seeing that there is so little sunshine, and the ground and atmosphere so moist. Peaches on open walls here have and are ripening off their fruit well; all the following kinds have furnished excellent fruit during the last two or three weeks, viz., Early Grosse Mignonne, Bellegarde, Sulhampstead, Royal George, Noblesse; and now Barrington and Walburton Admirable are ripening fast. As soon as the foliage manifests any tendency to drop, a light brush over with a hair broom will bring some of it down, and prove beneficial, especially where the wood is so crowded that the foliage intercepts the admission of light and air; no force, however, must be used to bring the foliage down, for until it parts from the trees with but the slightest pressure its functions are incomplete.—W. W.

Extracts from my Diary.—October 20 to 25.

FLOWERS.—Preparing border for planting Stocks. Planting border with Carnations and striped Pinks taken up from beds where they were layered, edged with variegated Watercress. Staking Adiantum Farleyense and Bouvardias, and placing the latter in the greenhouse for flowering. Looking over and surface-dressing *Deutzia gracilis* for forcing, also Prunuses and Lilacs. Taking standard *Laurustinus* from outside and setting them in cold houses for the winter. Getting bedding plants into Vinery.

FRUIT.—Pruning Black Hamburgh Vines and cutting out a few rods not required. Trenching up north border for Plums. Digging up Raspberry suckers. Cutting all ripe Melons ready for use. Looking over Apples and Pears in fruit room, and shelling Chestnuts ready for dessert.

VEGETABLES.—Trenching and manuring borders for spring cropping. Turning Mushroom manure. Tying and stopping Cucumbers and Tomatoes growing for winter use. Cutting all Broccoli ready. Getting handlights on sheltered borders ready for planting Cauliflower plants to stand the winter. Sorting seed Potatoes in store rooms; picking out those that are too small for seed. Cutting all Mushrooms ready for use, and getting remainder of Tomatoes into late Vinery to ripen. Potting Early Ashtop Potatoes in 8-in. pots and placing them in a cold frame. Looking over Tomatoes in Vinery and picking out bad fruit. Picking male blossoms off Cucumbers. Shelling Broad Beans for seed. Pouring liquid manure on Mushroom manure. Pulling up main crop of Nantes Carrots and Student Parsnips, and storing them away in heaps. Carting manure on ground ready for winter digging. Sowing a batch of Osborn's Forcing French Beans. Pulling up exhausted Cucumbers and preparing house for French Beans.—R. G.

GARDENING AT HOOLE HOUSE, NEAR CHESTER.

HOOLE HOUSE, which is approached by a winding carriage-drive planted on either side with ornamental trees and shrubs, is entered by a small glass corridor, in which some fine old plants of *Cassia corymbosa* are just now flowering freely. On leaving the house to the left, and passing through a small gateway, the rock garden and herbaceous beds are presented to view. Hundreds of fine herbaceous plants may here be met with; some of them very rare. These are grown in circular beds on the lawn. Among them I noticed *Lilium auratum*, with from 12 to 42 flowers on a spike; *Anthericum Renardi*, with upwards of 100 spikes of snow-white blossoms; *Coreopsis lanceolata* and *Gentiana septemfida*, all in good condition. The rockery, too, is most interesting, being a miniature representation of the Bernese Alps. It is thickly planted on two sides with Irish Yews and Ferns; amongst the latter I noticed *Cyrtomium falcatum* and *Adiantum pedatum*, both of which withstood the severity of last winter. *Cystopteris fragilis*, together with *Polypodium calcareum*, are also abundant here. The third portion of the rock and that which faces the house is almost completely covered with *Aubrietias*, which cling tightly to the rock. *Dianthus deltoides* and its white variety and *Ernus alpinus* are also all here associated with *Arenaria multicaulis*, which may be seen in abundance on every ledge of rock; the *Ernus* is allowed to drop its seed year by year, and, judging from the large tufts of it which are here, it must be a magnificent sight when in flower. Two plants I must not omit to mention are *Anthyllis montana* and *Phlox setacea*, tufts of both of which I saw large and fine. The former stands alone on a raised piece of rock about 2 ft. high, the sides of which are well clothed with its glaucous leaves. It had borne upwards of 150 flower-stems.

The glass department must not be overlooked; the range consists of conservatories, well filled with summer-flowering plants; Cucum-

ber and Melon houses, Vineries, stoves, Ferneries, Orangery, &c. In the Cucumber house was a plant of *Allamanda Hendersoni* trained to the roof, bearing upwards of 1000 fully expanded blooms. The house in which it is growing is some 30 ft. long and 12 ft. wide. The Cucumbers are allowed one-half of the roof and the *Allamanda* the other. The plant in question was from a cutting struck only three years ago; when large enough to handle it was transferred to a bed in one corner of the house specially prepared for its reception. A small collection of well-grown Orchids occupies a portion of the stove, in which are also many plants of *Scutellaria Mocciniana* flowering profusely, together with large quantities of *Achimenes*, *Gesneras*, and *Clerodendron falax*, and some good examples of *Dracanas* and *Crotons*. Suspended from the roof in a basket, and flowering freely, was a fine plant of the Mountain Bladder-wort (*Utricularia montana*) and an endless variety of other plants, which to name in detail would occupy far too much space. H. J.

THE INDOOR GARDEN.

CULTIVATION OF DUTCH BULBS.

HYACINTHS IN GLASSES.

FROM Hyacinths in pots to Hyacinths in glasses is a natural transition. The latter method affords a pleasant and delightful indoor recreation. There are many persons whose only chance of enjoying the sight of flowers is restricted to what can be done within doors; and to such the Hyacinth is one of the most suitable subjects that can be taken in hand. It is an easily-managed plant when grown in this way. Let the home-cultivator but start well, and then a small amount of attention, that never becomes irksome to one who loves the work, will bring well-developed and lovely flowers.

Now is the time to think and set about the culture of Hyacinths in glasses. As a rule it is not well to put the bulbs in water too early. After growing Hyacinths in glasses for many years I have come to the conclusion that it is well to select the bulbs early, taking care to have them sound and not too large for the glasses, and then put them in a dry and cool place until the ring at the base of the bulb shows signs of swelling, owing to the inclination of the incipient rootlets to become active. As soon as this occurs the bulbs should be placed in contact with the water. Some sorts root much more freely than others; among the latter may be included the deepest coloured reds. Robert Steiger is a charming variety for a glass, but it does not always root well, and I have tried the effect of placing the bulbs for a time on some moistened Cocoa-fibre, and so induced them to start into growth before the bulbs are brought into contact with water. They should not be allowed to remain in the fibre after the roots have gained the length of from $\frac{1}{4}$ in. to $\frac{1}{2}$ in., as they then begin to take an outward direction, and a little difficulty is experienced in getting them into the glasses; besides they are very brittle at that stage of growth, and need to be handled with care.

Now as to the glasses. Let us hope that the old, tall, upright chimney is now quite abandoned. It is ugly in shape, common in appearance, and top-heavy with the weight of the spike. The support for fixing the spike is a clumsy contrivance, and always unsatisfactory. When the late Mr. G. P. Tye, of Birmingham, introduced his registered Hyacinth glass many years ago, this difficulty was obviated, for while it was well suited for the growth of Hyacinths in water, it was also an elegant chimney-piece ornament, and well suited for holding cut flowers in summer. Hyacinth glasses are now manufactured of various materials, and in handsome designs, and having supports well suited for the purpose for which they are intended.

The tendency of the water in Hyacinth glasses to become putrid is a difficulty with many. I have found it of great value to place in each glass a few small pieces of charcoal, and this seems to keep the water sweet. The glasses are filled up sufficiently high with clear fresh rain-water, and the charcoal is dropped into it. Then the bulbs are placed in the glasses, allowing the water just to touch the base of the bulb. Rain-water should not be employed unless quite fresh and clear, or otherwise it soon emits an offensive smell, and causes the roots of the bulbs to decay. If there is no alternative but to employ hard water, it should be exposed to the influence of the sun for a day or two previously. The glasses can then be placed in a cool dark cupboard or closet, or in a dark cellar for a time, to induce them to root downwards before they begin to make an upward growth. I do not think this is so necessary as is generally supposed, but it is so constantly recommended that one can hardly be an exception to the rule. I have grown very fine Hyacinths in glasses without placing the glasses in the dark, but I always prepared the bulbs for the glasses as above recommended.

There are many failures with Hyacinths in glasses, but it is not the fault of the bulbs but of the indifferent treatment they receive. Two causes operate to bring about a failure, viz., keeping the glasses in too warm a temperature, and refraining from giving the necessary supplies of water. Perhaps there is one advantage after all in placing the glasses in the dark for the space of six weeks or so, namely this, that during that time the bulbs, when least interesting, are subjected to a uniform temperature, and do not get unduly excited into growth. When the glasses are brought to the light they should be placed near the window, where plenty of light and air can be given them. After Christmas the growth will be rapid, and the prime requisites are to keep the plants growing sturdily, to take care they do not become drawn in the foliage, to have the water sweet and wholesome at the roots, and to keep the water in the glasses up to the base of the bulbs. As soon as the spike of flowers becomes tall enough, the support, which can be bought with the glass, should be placed in position, and as the spike lengthens, the supporting hook should be raised to the necessary height.

Hyacinths in glasses are, as a rule, badly managed in the extreme, for it is not unusual to see a spike of flowers hanging down over the top of the glass from want of a support, and the glass but half-filled with water. It is a rare exception to see Hyacinths well grown in glasses in the windows of houses; and yet they can be grown there very finely indeed!

Next to Hyacinths, the only Dutch bulb that can be grown in water with anything like satisfaction is the Polyanthus Narcissus; but these become somewhat drawn, and the perfume they exhale is so powerful as to be even disagreeable in a close room. Scillas, Crocuses, Tulips, &c., all are more or less disappointing, unless they receive the closest care and attention, but even then they are seldom so satisfactory as could be desired.

Those who live in cities and towns can do far more in the way of growing Narcissus, Crocus, Tulip, Scilla, Hyacinth, &c., in pots than is generally supposed. Pots cost but little, and they need not be very large. Soil can be got from any seedsman or florist, and the purchaser will do well to procure also a little fine Cocoa-fibre dust and mix with the soil, and a little coarse white sand also. The pots should be well drained, and the bulbs three parts buried. But what can be done with these when potted? I have had to face such a difficulty as this, and surmounted it by buying a large Tea-chest or two, sawing them in halves and making them into two boxes, and then placing them in a back yard; I put the potted bulbs in them, and cover them with Cocoa-nut fibre refuse. I always raised the box and pots on bricks, so that all rains would freely pass away. A piece of galvanised wire was put over each box to keep the contents from interference by cats, and, as in the case of the exhibition Hyacinths, the pots should be lifted out when they commence to make an upward growth, and taken into the house and gradually inured to the light, and kept in the window as cool and airy as possible. A few common clay saucers with a little coarse gravel in them need to be provided for the pots to stand in, and these will be found a positive advantage, as evaporation takes place in a rapid manner in a sitting-room where a fire is constantly maintained during winter. In this way excellent flowers can be had, bright and effective in appearance, putting one in mind of the flush of spring that will by-and-by pervade the face of Nature. I have found that such flowers are harmed but very little by any gas burned in the room. If dwellers in towns would try, they will be both surprised and delighted with the success that will result from their efforts, if practised with ordinary care and attention. Some care is necessary in selecting suitable Hyacinths for growing in glasses. The single varieties are undoubtedly the best, and a selection of those most suitable might consist of Duchess of Richmond, bright pink; Emmeline, delicate blush striped with pink; Gigantea, pale flesh; La Dame du Lac, blush, suffused with pink; Madame Hodson, light pink; Norma, waxy flesh colour; Robert Steiger, or Maria Catharina, fine deep crimson; and Sultan's Favourite, flesh striped with pink. All the foregoing are classed with the single reds. Of single blue varieties the following are very good for the purpose; Baron Van Tuyl, deep glossy purple; Bleu Mourant, dark blue; Charles Dickens, bright porcelain blue; Emicus, blue with light centre; Grand Lilas, delicate azure blue; Leonidas, clear bright blue; Mimosa, dark blue purple; Orondates, pale porcelain blue; Prince Oscar, striped deep blue; and Regulus, shaded lavender blue. The best single white varieties are alba superbissima, pure white; Cleopatra, creamy white; Grandeur à Merville, waxy French white; Grand Vainqueur, pure white; Mont Blanc, pure white; Seraphine, creamy blush; and Themistocles, pure white. Of single yellow varieties, Anna Carolina, clear yellow; Heroine, pale yellow; and King of Holland, pale yellow shaded with reddish-orange.

The foregoing are cheap varieties, the prices bringing them within the reach of all. There are, of course, more expensive varieties which can be selected at the will of the cultivator. R. D.

Selaginella helvetica.—"A. D." (p. 194) recommends this *Selaginella* as a capital rock and carpet plant, but doubts its hardiness. A large quantity of plants of *Selaginella helvetica* remained uninjured in the open ground in my nurseries for the last six years without the slightest protection. This will, I think, sufficiently prove its being quite hardy.—A. N. C. JONGKINDT CONINCK, *Dedemsvaart, Netherlands*.

LOW'S NECKLACE VANDA.

(VANDA LOWI.)

THIS is one of the most striking of Bornean Orchids. At the foot of Sirambau, in the province of Sarawak, is a warm spring, and on the trees and rocks around this plant abounds and produces its necklace-like drooping flower-spikes plentifully. Its habitat is

Vanda (Renanthera) Lowi, showing epiphytal habit of growth.

interesting and is visited by most travellers, in Sarawak as it is within easy reach of the capital, and although the way to the summit, up rugged paths, through shady forests, close jungle, or Dyak clearings, is rather toilsome, one is rewarded on reaching the top; there a pretty cottage was erected by the late Sir James Brooke at a spot called Peninjau, or "long view" rock. Close at hand is a natural bathhouse, a cave through which the coolest and purest of waterfalls flows, and the lower slopes are covered with fruit groves of large extent, the Durian trees here being especially large and handsome. *Vanda Lowi* has never been a common plant in collections; it is rather difficult to establish by modern Orchid growers who, as a rule, starve this species and its allies *V. cœrulea* and *V. Cathcarti* by withholding water during the winter months. Now that the plant is again being imported, and is likely to appear in still greater quantities at auction sales, however, let not our home growers forget that it grows naturally in the hottest and wettest climate in the whole world. With many the reputation of the plant has suffered by its having been reported that only plants of elephantine proportions would yield

flowers. This is a misconception, as small plants, if liberally supplied with water and heat, and kept near the glass in full sunshine from the time they are received as imported, will bloom at 12 in. to 18 in. in height, producing spikes three or four times their own length. The fact that the two first flowers, *i. e.*, those nearest the plant, are of a different colour from the others is well known—the reason of their being so is not, however, very apparent, at any rate not definitely known. The long drooping spikes dangling among other vegetation may, perchance, like the tails of *Selinipedium*, *Cirrhopetalum*, *Uropedium*, and *Aristolochia*, serve as ladders for wingless insects whose presence may be essential to fecundation. The long spikes of golden crimson-blotched flowers last long in perfection, and are singularly beautiful as well as quite distinct from those of

that an old plant of it which we have here, that has probably seen thirty summers, on the back wall of a greenhouse has been one of the most floriferous plants of the year, and as yet shows no sign of losing its load of blossoms. I think that some of the older varieties of *Fuchsia* are well worth looking after for walls or pillars, for few of our indoor plants can equal them either in beauty or in continuity of flowering, and when planted out they are seldom attacked by insect pests like those in pots, their increased vigour appearing to defy the ailments to which plants in pots are liable.—J. GROOM.

COOL ORCHIDS.

IN reply to "C." (p. 336), I wish to say that the object of my previous remarks (p. 305) was to show that *Odontoglossums*, &c., could be well-grown as cold house plants, by giving a detailed account of how mine had been treated, and not to condemn any other mode of treatment. At the same time I wished those who give their Orchids much heat to bear my remarks in mind so that they might avail themselves of them should anything untoward happen to their plants. The reason I remove them in September from an unheated house to one in which piping is placed is that they may be kept in that house for some time without artificial heat, in order to accustom them to it before it is necessary to apply a little heat so as to maintain the proper temperature at this season of the year, *viz.*, 50° by night, and 60° by day, rising a little more with sun-heat. To the second query I reply that the advantage of cool treatment (if consistently carried out) is that the plants in all stages do equally well together, very few of them requiring rest in the ordinary acceptation of the term. With respect to the general condition of the plants treated as I have described, almost all the bulbs show a marked improvement on those previously made—an improvement which has been constantly going on. They make two sets of bulbs each year, and those which are strong enough (often some very tiny plants) flower from each bulb, and do not shrivel as they do in heat while flowering. Many are now in flower, and quantities are sending up spikes, some as thick as a stout quill pen. *Odontoglossum cirrhosum* I did not move to a north house in May, with the exception of a few plants which did fairly well. I think "C." misunderstands me in reference to the recommended minimum temperature of 45°. I advise it only as the lowest night temperature during the dead of winter. While on the subject of cool Orchids, it may be well to mention a circumstance which, in my opinion, is not irrelevant. About five weeks ago there came up from among the roots of some *Cologynes* freshly imported from Assam, two little plants from seed evidently imported amongst the roots of the *Cologynes*; being too small to recognise, I potted them into small pots, and kept them in the warm house; in about a week they had pushed out a sickly-looking leaf or two, but sufficiently large to enable me to recognise what they were. They were without doubt *Chrysanthemums* of the large-flowering section. Had they been something I did not know, they would perhaps have been left in the warm house to die; as it was, I removed them to a very cold house, and in a week gave them a liberal shift into 5 in. pots, with good soil having a sprinkling of Clay's Fertiliser in it; the one measures now 1 ft. across, and the other 1 ft. 6 in.—short, stout plants. I say, in the case of plants growing naturally on the same spot, can the mere fact of one being an Orchid and the other a *Chrysanthemum* make the one a hothouse plant and the other a plant which will positively and certainly die in a hothouse? I think one may take it at least as a gentle hint that the *Cologyne* in question, as well as all the rest of the Orchids from the same locality, will grow well without much artificial heat. JAMES O'BRIEN.

Blooms of *Vanda Lowii* ($\frac{2}{3}$ natural size).

any other species of the genus. Our sketches show the natural habit of growth assumed by this plant in its native habitat, and flowers two-thirds their natural size. B.

Fuchsia corallina.—Some twenty years ago this *Fuchsia* was largely grown for covering roofs of greenhouses or as a pillar plant, as its vigorous habit of growth and continuous flowering made it a showy and suitable plant for such situations. I remember a fine example of it at Cliveden, which, being inarched with various light-coloured sorts, had a pretty effect drooping from the roof in large masses; and some of the large standards at Dropmore, that used to be plunged out in summer were, I believe, of this variety. It is now well-nigh superseded by double or semi-double sorts, but I must say

Training and Tying Plants.—Mr. Baines' description and condemnation (p. 304) of specimen-trained *Pelargoniums* and *Chrysanthemums* as monstrosities, which, he says "are painful to look upon"—and I agree with him—looks very like the pot calling the kettle black. I have often seen such specimens as he describes, but never admired them any more than I did Mr. Baines' formally-trained *Ixoras*, *Heaths*, *Azaleas*, and other plants which, so far as training was concerned, differed in no way from the *Pelargoniums* of his neighbour in the next tent, except in so far as the necessities of the different subjects demanded. It would puzzle Mr. Baines, I fancy, to tell us why a flat or a round *Pelargonium* or *Chrysanthemum* should excite feelings of pain in the beholder, and a globular or flat-headed *Heath* or *Ixora* or pyramidal *Azalea* should not, examples of which Mr. Baines has often exhibited in his time. It is perfectly well known that Mr. Baines' exhibition plants were models of the perfectly formal style of training, as those who have seen his plants during his career as an exhibitor can testify, and I doubt if ever he raised his voice as a judge of *Pelargoniums*, in which class, I imagine, he has often officiated, against their formal training. His objection,

too, against pyramidal-shaped trellises for Azaleas is quite beside the mark. The question is not the way of manufacturing such specimens, but, of making them at all. What is the difference between Mr. Baines' pyramids built up without a trellis and one formed by the aid of such a contrivance which, I presume, is designed to simplify the matter, while the end accomplished is the same in both cases?—CONSISTENT.

Filmy Ferns.—If Mr. Brook will refer to the *Gardeners' Chronicle* of 1st March last (p. 276), he will find there suggested the plan he has tried practically (p. 337)—a pit or sunk frame in which to grow filmy Ferns. I believe with him that many of these are much more hardy than is generally supposed. No class of pot plants requires less care or attention if the situation in which they are placed is favourable, and no vermin that I am aware of ever attack them. A hole dug in a damp shady spot, and covered with a sheet of glass, where, as Mr. Brook says, little else would grow, would suit admirably, and a small piece of ground so situated might contain a large and valuable collection. If the ground is naturally moist enough the plants might be left for days or even weeks without care. Unfortunately filmy Ferns are very expensive, and beyond the reach of those who probably would appreciate them most. Self-sown *Todeas* are plentiful with me, however, and I could spare a dozen or two of seedlings to persons wishing to try the experiment on sending me an addressed envelope. I should like much to see the cultivation of this beautiful class of Ferns more widely spread. Mr. Thomson, formerly Government Botanist in Jamaica, also speaks of the hardiness of filmy Ferns in their native habitats. I happened to make his acquaintance lately in Edinburgh, and asked him to come and see a collection of filmy Ferns which I had received some years ago from a friend in Jamaica, and which were growing very satisfactory. He looked at them attentively and said, "Why I gathered these and packed them myself for a gentleman who said he was sending them to a friend in this country!" A few weeks ago I received another case of *Filices* from Jamaica, containing species different from the previous case, but unfortunately it had been packed by other hands than Mr. Thomson's, and all were dead.—P. NEILL FRASER, *Rockville, Murrayfield, Edinburgh.*

TREATMENT OF UNHEALTHY PLANTS IN POTS.

WHENEVER a plant shows signs of failing health the cause should be ascertained. If the plant showing signs of unhealthiness, such as sickly growth, be an old one, the best plan to do—in the case of hard-wooded plants—will be to reject it and begin with a young one, and try and avoid the error that led to the loss. Many hard-wooded plants are lost through being cramped too long in small pots in the young state, and then a sudden change to a more liberal regimen. These plants should be treated by gradually increasing their food supply; but perhaps the best course would be not to purchase such plants at all, as smaller plants that are young and thrifty are best adapted for forming handsome specimens; in fact, those that have been starved rarely attain old age. Immoderate or careless watering is the principal cause of unhealthiness in plants, and as soon as the first symptoms of disease appear, insects, mildew, &c., infest the plants, which might all be traced to a month or two of careless watering; or even so simple a matter as a badly placed crock in the drainage may cause all the mischief by obstructing the passage of water and free action of air. Unhealthy soft-wooded plants, even if large, may be restored to health by ascertaining and remedying the cause of the evil. This should not be a difficult matter. If a plant has had too much water, give it less. If the drainage be defective, turn the ball carefully out and arrange it properly; at the same time if the soil is sour and in a water-logged condition, remove as much as can be done conveniently, and transfer the plant to a clean, well-drained pot, and pot carefully in fibry soil well rammed down. Even soft-wooded plants should be potted firmly if dwarf and bushy and well flowered specimens are required. Cleanliness is a necessity in good plant culture; dirty pots and houses are sure signs of carelessness and neglect, and in such places unhealthy plants are commonly found.—E. H.

English and French Flower Shows.—Owing to my hasty writing several mistakes occur in the paper under this heading in last week's *GARDEN*. One I am particularly anxious to correct—that in which I am made to say there were eight amateurs who entered for the show of the National Rose Society at the Crystal Palace. It should have been eighty, as I wrote it, though doubtless illegibly.—DELTA.

A New Pot Scrubber.—We have received from Mr. H. C. Smythe, of Endell Street, Long Acre, a new form of a pot-washing brush made entirely of Cocoa-nut fibre. It is cheap, simple in construction, light yet firm, and is said to be very durable.

USES OF LEAF MOULD.

THERE are few people who have had much to do with the cultivation of either hardy or exotic plants but know something of the influence that leaf mould has upon the growth of those subjects for which it is commonly used. Of all vegetable substances with which we in this country are acquainted, there is nothing that has such a tendency to promote quick top growth, especially in soft wooded plants. Its effects upon plants like *Calceolarias*, *Cinerarias*, *Petunias*, *Fuchsias*, *Chrysanthemums*, *Salvias*, and *Primulas* in their early stages are always apparent by the quick growth and large ample foliage produced, so far as its use goes in the cultivation of pot plants. It is for these and a few others of a similar character, occupants of either stove or greenhouse, that it is best suited; and even in the case of the above, I would by no means employ it in the quantity many growers think beneficial. The influence it exerts on young stock from the seed-pan or cutting-pot up to the point when they have attained considerable growth, often leads to an unqualified impression in favour of its use; but it very frequently happens that when the time of flowering comes the appearances borne in their early stages turn out to have been somewhat deceptive, through the amount of bloom not being forthcoming which might have been looked for from the luxuriance of the plants.

Where nothing but a very inferior description of loam is to be had containing an insufficiency of vegetable fibre, then a liberal admixture of leaf-mould can no doubt with advantage be used; but when good loam is obtainable it will be found that a comparatively small quantity gives better results. Leaf-mould is often mixed with the soil for potting plants of a hardier description than those named, that have not to be shaken out and the greater portion of the material removed yearly; here its use is still less admissible, as it is destitute of the lasting properties essential to support health and vigour; the leaves of evergreen subjects formed under its influence are deficient in fibre to enable their continuing in a healthy state nearly so long as those produced by loam or peat without it; and however firm the soil is made in the operation of potting, it always shrinks to an extent that leaves the ball in a condition too loose and open consistent with the well being of the roots. Where I have found leaf-mould of the most service, has been where the loam available was of an over-strong, close description, and on using it for cuttings or seedling raising, a considerable portion of leaf-soil, say one-third, is better than an excess of sand, as the seedlings or young rooted plants can be moved without the breakage of their fibres that takes place if the soil is closer, and the vegetable matter furnishes fitting food for the young roots; this is especially the case in raising seedlings of half-hardy or hardy plants that have afterwards to be pricked out into pots, boxes, or seed beds. Again, in the use of leaf-mould its advantages depend a good deal upon the condition it is in when used.

Many of the old north country florists, growers of soft-wooded plants, with whom I was many years ago acquainted, often pointed with satisfaction to the age of the different potting materials they used, such as cow manure six or seven years old and leaf-mould possibly half as much; but in the case of the latter, when so far decomposed, much of its useful properties are lost, as when used in this condition it soon gets into a soft pasty state, all the fibre which it contains, in which half its value consists in keeping loam of a close nature open and porous, being gone. A mixture of leaves, such as Oak, Beech, Elm, Lime, and Sycamore combined, when they have lain together in a considerable heap for twelve months, so that they can be rubbed through a sieve, are very much better than when further reduced to a rotten condition. T. BAINES.

Use of the Telephone in the Seed and Nursery Trade.—In visiting the seed and nursery establishment of Messrs. Dickson & Co., Waterloo Place, Edinburgh, the other day, I was not a little struck with the fact that they could transact business in their shop, Waterloo Place, and in their nurseries simultaneously. That is to say, their nursery foreman could negotiate a bargain with a customer in the shop while he remained at his post in the nursery a mile and a half distant. This was done by means of a telephone—Crossley's Patent Transmitter. The wires are conveyed over the tops of the houses for about a mile, with instruments for the transmission of messages at the shop and in the nurseries respectively. Signalling is done as follows; A small nut or spring on the instrument at one end is touched, a bell rings at the other, a return bell rings on your end. The message or conversation is then conducted by placing the conductor of the return wire to the ear and speaking in a subdued tone into the instrument. By this means conversation can be carried on with the party at a distance quite as well and as audibly as if the party were sitting with you in the same apartment. This is a most ingenious and, I understand, comparatively inexpensive machine, and the benefit of having the use of it applied to

the conduct of business must be most valuable. I am sure that the firm referred to with their usual urbanity will be glad at any time to exhibit its advantages to any parties desiring to see it work.

—AN OBSERVER.

GARDEN DESTROYERS.

THE ASPARAGUS BEETLE. (CRIOCERIS ASPARAGI.)

THE Asparagus beetle is one of the prettiest of our English beetles, but Asparagus growers are, unfortunately, unable to regard them with such unmixed pleasure as an entomologist can, as they are so often the cause of much damage to his plants. If not kept well in check, the grubs of this little beetle destroy the foliage of the Asparagus to such an extent as to very considerably weaken the plants; they not only devour the leaves, but also eat the bark of the stems. Late in the season the heads which are cut for the table are sometimes spoiled by the large number of eggs which are laid on them. On the Continent the Asparagus seems to suffer from the attacks of this insect more than it does in England. M. Godefroy-Lebeuf, in his recent articles in THE GARDEN on the cultivation of Asparagus, states that "These destructive insects will devour a whole planta-

Asparagus beetle, &c.

Fig. 1.—The Asparagus beetle (magnified). Fig. 2.—The grub (magnified). Fig. 3.—The cocoon (natural size). Fig. 4.—Branch of Asparagus showing grubs and eggs (natural size). Fig. 5.—Eggs (magnified).

tion in a brief time if their ravages are not checked immediately they are perceived." Though our Asparagus beds, fortunately, do not suffer so severely as those of Argenteuil, every precaution should be taken to prevent this insect increasing to such an extent as to render such damage possible. The destruction of this insect is a troublesome matter, but it is by no means a hopeless task. When the Asparagus is being cut, a sharp look out should be kept for the beetles, which will just be beginning to make their appearance; and it is these early ones which it is most essential to destroy. When disturbed they feign death, and drop to the ground, so that some little care must be used in their capture. Later on in the season, when the plants have grown up, an open umbrella may be held so that they may be shaken over it, when the beetles are sure to fall into the umbrella, from which they may easily be turned into a vessel of boiling water, or on to some hard substance and crushed. The eggs (figs. 4 and 5), after a little practice, will be found without any difficulty, as they stand out at right angles to the leaves, which should be gathered and destroyed. In searching for the eggs it is as well to choose a day when there is little wind or sun; the former makes the delicate sprays move, when it is difficult to see the eggs, and the shadows caused by the latter are very confusing. The grubs (figs. 2 and 4) may be shaken off in the same manner as the beetles, but they generally cling pretty tightly to the leaves, so that perhaps gathering or cutting off the shoots on which they are and burning them is the most efficacious method of destroying them. The

gardeners' best allies in getting rid of this insect are the small birds, and it is no doubt greatly owing to their being so comparatively scarce on the Continent that this and various other insects are so much more troublesome there than they are in this country. The beetles generally make their first appearance in April, and may be found throughout the summer until September, during which period there are probably two or more generations; but, as beetles, eggs, and grubs may all be found together at the same time, it is difficult to ascertain how many with any certainty; the entire transformations are gone through in about six or seven weeks; they lay their eggs generally singly (but sometimes one may be found on the top of another) on the young leaves or shoots; in about a week or ten days the grubs are hatched, and begin feeding on the leaves, which they entirely destroy. When disturbed they raise their heads slightly, and emit from their mouths a drop of a blackish fluid, which at first sight gives them the appearance of having unusually large heads (see fig. 4). They change their skins several times, and are fully grown in about a fortnight or rather less; they then drop to the ground, and, having buried themselves, form thin papery cocoons, within which they become chrysalides; they remain in this condition about a fortnight or three weeks, at the end of which time the beetles emerge. Some of the beetles of the last brood, according to Mr. Westwood, survive the winter, probably sheltering themselves in the earth. The Asparagus beetle belongs to the family Chrysomelide, 329 members of which are natives of this country; they are all vegetable feeders, both in the grub and beetle states; they may generally be found on the leaves of plants. The genus *Crioceris* only contains three species, all of which are injurious; besides the subject of this paper *C. duodecim-punctata* also attacks the Asparagus, and in the same manner as the Asparagus beetle; it is fortunately, however, rare in this country, although in some places on the Continent it is more abundant than the other. The third species, *C. meridigera* or the Lily beetle, is at times the cause of much injury to the leaves of Lilies, but it is by no means common. The Asparagus beetle is about $\frac{1}{4}$ in. long, and is very glossy. The head is of a shining bluish-black colour, and furnished with a pair of long black antennae composed of eleven joints; the eyes are prominent and reddish. The thorax is rather longer than it is wide, with nearly parallel sides, and is covered with minute punctures; its colour is a brownish-red. The wing-cases are considerably wider than the thorax, and are striated with a number of longitudinal rows of fine punctures; they are of a yellowish colour, with the outer margins rather darker; the inner margins are bluish-black, forming, when the wing-cases are closed, a dark central longitudinal band. Each wing-case is further ornamented by three bluish-black spots, one of a rather peculiar shape on the shoulder, a somewhat triangular one in the centre (with one of its angles almost, and sometimes quite, touching the central band), and an oval one near the tip. The legs and feet are bluish-black, with the exception of the upper part of the shins, which are reddish. The description of this beetle given by M. Godefroy-Lebeuf in THE GARDEN of September 27, 1879, is by no means correct; he states that "It is of a red colour sprinkled with grey and white spots." The eggs are skittle-shaped, about $\frac{1}{20}$ th of an inch long, and of a deep shining brown colour. The full-grown grubs are about $\frac{3}{8}$ in. long. Their heads are black, their bodies of a greenish-slate colour, and composed of twelve joints; they gradually increase in size to the eighth, which is the largest, and then diminish. The joints are much wrinkled; the first three each bear a pair of black legs, which are very crooked, giving the grub a good hold on the narrow leaves. The remaining joints are furnished with fleshy tubercles, which serve the purpose of legs; just above these tubercles is a rather paler band, in which are the spirales or breathing pores. The chrysalides or pupae are about $\frac{1}{4}$ in. long, and are enclosed in a thin membranous cocoon of a dirty yellowish-brown colour.

G. S. S

The Auricula Aphis.—I have no wish to continue a discussion on this horrible pest, but must put myself right with regard to Mr. Douglas's observations (p. 332). I did not say that I had lost my collection by it, nor did I say that I had found paraffin unsuccessful. On the contrary, I stated that after using it I found that I had been "fairly successful with it." The case is simply that Mr. Douglas has never had it; I have. So happily ignorant about it is he, that I suppose it is that which he some time ago called mealy bug. He says, "If you get it, wash the plants well;" to this I replied that I had done so, and others had done so, but that we failed to eradicate it. On my mentioning Mr. Llewelyn's remedy (not mine), he advises it not to be done, but gives no reason; he still maintains his position simply on his own *ipse dixit*, and sets that opinion in opposition to those who have practically tested its efficacy. I may add that I received the other day a letter from one of our great northern growers, who has about 3,000 plants (seedlings excluded), and that he tells me a neighbour of his—one well known

as an exhibitor and raiser of first-class varieties—is nearly worried out of his wits by it. So again I need repeat do not pooh-pooh it, for it is a very formidable pest. So some ridiculed the Phylloxera at first, they could get rid of it; but, alas, its ravages increase, and Vine culture stands in danger.—DELTA.

The Short-tailed Field Mouse in the Garden.—This is a very active enemy in the gardens at Bodorgan, attacking and destroying various vegetables and hardy plants, and even entering the houses and barking the Vines at the base. The systematic destruction of the smaller vermin-destroying birds and animals has not been good for the garden.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 14.

THERE was on this occasion an unusually interesting display, which, notwithstanding the lateness of the season, was, in point of attraction, decidedly superior to many that have occurred earlier in the season. Fruit was especially numerous, there being upwards of 200 bunches of Grapes shown, and all in excellent condition; and of Apples and Pears nearly the same number of dishes. These latter, however, were much below the average both in size and quality compared with that of ordinary seasons. Half-a-dozen Smooth Cayenne Pines were shown, which were, as regards size and form, as near perfection as possible. Tree Carnations, which were supposed to be forthcoming on this occasion, were conspicuous only by their absence, but their place was well filled by several interesting collections, especially that of winter bedding plants, consisting of hardy shrubs, skilfully and neatly arranged, which occupied a large space.

First-class Certificates were awarded to the following plants:—

Cypripedium Spicerianum (Veitch).—A remarkably distinct and very handsome Lady's Slipper. Its foliage is but slightly mottled; the flower, which is borne erect on a short stalk, has a pouch-like lip, of a green colour, obscurely netted with purple lines, the lateral segments of the same colour, with a conspicuous purple stripe along the middle of each; the upper part is white, also with a broad intermedial purple line, and the bright purple centre considerably relieves the dull colour of the other parts.

Pachystoma Thompsoni (Veitch).—A beautiful and highly interesting new Orchid, of which a note will be found in another column.

Oncidium dasytyle (Veitch).—The flowers of this species are comparatively large, with a broad lip of a pale yellow colour, as are also the other divisions, but which have in addition a few blotches of brownish-chocolate. The most remarkable part of the flower is the black velvety crest, which gives it the appearance of an insect.

Nepenthes Outramiana (Williams).—A handsome hybrid, the result of a cross between *N. Sedeni* and *N. Hookeri*. The pitchers have the same bright colour of the former with the size and form of those of the latter kind. It is a fine addition to this interesting class of plants.

Cocos elegantissima (Williams).—A very elegant Palm with the leaves in the way of *C. plumosa*, but with a gracefully arching habit which renders it a valuable decorative subject.

Calamus densus (Williams).—Also an elegant Palm with the leaves arranged in a dense manner as its name implies, and forming a handsome compact specimen.

Adiantum Bausei (Wills).—A very distinct and handsome Maiden-hair Fern supposed to be a hybrid between *A. trapeziforme* and *A. decorum*. As it appears to be intermediate between the two in point of habit and other characters, the surmise no doubt is correct.

A. cuneatum dissectum (Bull).—A pleasing variety, having the pinnules deeply cut, which gives the plant an elegant appearance, and makes it desirable as a decorative plant.

A. mundulum (Bull).—A variety similar to the well known *A. cuneatum*, but considerably dwarfer in habit, and the fronds, moreover, are not so drooping as in the ordinary Maiden-hair.

Polystichum lentum (Bull).—A dwarf Fern of compact growth, with fronds nearly 1 ft. long, lance-shaped, with the pinnæ ending in bristles.

Coleus "Majestica" (King).—A variety with coarsely-toothed leaves, edged with a golden tint, with a broad midrib of bright green, and the intervening space of purplish-crimson hue.

Dahlia George Thomson (Turner).—A fine bedding variety growing from 15 in. to 18 in. in height, very floriferous; the flowers are bright yellow, moderately large, and of fine form.

Cycnoches Warszewiczii (Bull).—A botanical certificate was awarded this Orchid; it is alluded to in another column.

In addition to those mentioned above, there were in the group exhibited by Messrs. Veitch several other interesting plants. Amongst these were *Cœlogyne Massangeana*, with a long, pendulous raceme of creamy-white flowers with the lip pencilled with chocolate, and the crest golden. The red-striped variety of the Golden Lily (*L. auratum rubro-vittatum*) was shown with several flowers, which were, unfortunately, past their best; it is a very distinct and handsome form, though at present very rare. The white-flowered variety of the pretty little *Oncidium ornithorhynchum* is an interesting plant; the flowers are quite white, except a spot or two of yellow. *Mormodes Ocañaë* is a handsome Orchid, with large blossoms copiously spotted with chocolate. A fine variety of Carnation, named Lady Musgrave, is a desirable kind, as it has such a distinct erect habit of growth, with very glaucous leaves, and large, well-formed flowers of a rich deep crimson. Several fine Orchids were conspicuous in Mr. Williams' collection, more especially good examples of *Vanda cœrulea*, *Oncidium tigrinum*, *O. varicosum* major, *Dendrobium superbiens*, *Maxillaria nigrescens*, with large, deep reddish-brown flowers, and *Cypripedium barbatum* purpureum, a variety with flowers of a deeper tinge of purple than the ordinary kind, and the beautiful golden *Dendrobium chrysotis*, which is not often seen in flower. A handsome plant of *Croton Rodeckianum*, with long, narrow, gracefully-arching leaves of beautiful golden, green, and crimson variegation, was also noteworthy. Several plants of the exquisite *Pleione lagenaria* formed an edging to this group, which had a fine effect. Mr. Bull also contributed an interesting collection, amongst which were the beautiful *Tillandsia Lindenii* (genuina), with its rosy flower-stems, and rich purple blossoms; the elegant *Curculigo recurvata striata*, and *Kentia Luciana* and *Zamia Skinneri*, bearing several cones, which was awarded a cultural commendation. In the same group were also the singular bronzy-flowered *Masdevallia velifera*, some beautiful kinds of *Oncidium*, and a fine form of *Bollea cœlestis*. Mr. Green brought, as usual, some interesting plants from Sir G. Macleay's garden at Pendell Court, Bletchingly, consisting of *Brunsvigia Josephinae*, with a huge head of flowers nearly a yard through; also cut specimens of *Passiflora Hahnii*, a beautiful species with ovate, pointed leaves, purple on the under surface, glaucous green above; the flowers are produced singly on the axils, and are white with a broad golden fringe; and a plant in flower of the exquisite little *Bulbophyllum purpureum*, with the segments of the flowers of a creamy-white, spotted with deep purple specks, which at first sight reminds one of *Restrepia antennifera*. Messrs. Wm. Paul & Sons, Waltham Cross, exhibited half-a-dozen trays of cut blooms of Roses, which, considering the season, were excellent. Of the beautiful variety *Duchess of Bedford* there were some good examples, and the Teas were in fine condition also. Mr. Noble, Bagshot, sent a bedding variety of Rose named *Queen of Bedders*, of dwarf compact habit, very floriferous, with flowers of a deep crimson. From Mr. Cannell came a collection of *Dahlia*s of the florist's type, which were excellent, as were also the cut blooms of the single-flowered kinds that he has previously exhibited, together with the singular Cactus-flowered *D. Yuarezi*. A collection of the useful early-flowering *Chrysanthemum*s in rich variety was also shown from the Swanley Nurseries. *Dahlia*s were also shown in fine condition by Messrs. Rawlings Bros., Romford, who sent four dozen blooms of the show and fancy varieties. Mr. Turner, Slough, also showed the *Dahlia* well, and his new yellow bedder *George Thomson* will no doubt prove a most useful variety. Mr. Walker, Thame, Oxon, exhibited a quantity of cut blooms of *Tropæolum tuberosum*, the scarlet and yellow blossoms of which made an attractive display. Though an old introduction it is but seldom seen in gardens, and certainly not so fine as Mr. Walker showed it. This was deservedly awarded a cultural commendation. Mr. J. King, Reigate, sent half-a-dozen new forms of *Coleus*, some of which were very distinct and pretty, and one was awarded a certificate. Mr. Chambers, Westlake Nursery, Isleworth, sent some interesting varieties of Ferns, chiefly forms of *Pteris serrulata*, for which he was accorded a vote of thanks. One named *cristata fimbriata* was particularly elegant, and no doubt will prove a good decorative kind. Mr. R. Dean contributed cut blooms of *Physostegia imbricata*, a pretty *Labiata* with purple-lilac flowers; also a plant of *Marigold Diadem*, said to have been found in a cottage garden in Kent. The flower-heads were large, of perfect form, and the florets were lemon-tinted, with a distinct edging of deep orange, which has a very pretty effect. It is said to perpetuate itself quite true from seed, which much in-

creases its value. From Messrs. Haage & Schmidt, Erfurt, came cut flowers of a similar variety named Meteor, but as it was shown it was much inferior both in point of size and colour of blooms. The same firm also sent cut flowers of the handsome *Salvia farinacea*, a Mexican plant with lavender-coloured flowers blotched with white. Cut blooms of *Begonias* were sent by Messrs. J. Laing & Co., Forest Hill, including the superb Stanstead Rival, Reine Blanche, and other beautiful kinds. A similar contribution was also sent by Mr. Chambers. Mr. G. F. Wilson, Weybridge, exhibited cut flowers of the Closed Gentian (*G. Andrewsii*) and the Vaccinium-leaved Polygonum (*P. vacinifolium*), which are both useful plants for the rock-garden. In the Hall adjoining the Council Room, Messrs. Lee & Son, Hamersmith, exhibited a collection of hardy shrubs suitable for embellishing garden borders in winter. They consisted chiefly of Conifers, Euonymuses, Ivies, and other fine-leaved shrubs, tastefully arranged in neat designs; one side was edged with ordinary Box, and the other with *Euonymus microphyllus*, which is a capital substitute for it. The collection was, as last year, awarded a gold medal.

Fruit.—The Grapes shown on this occasion were, as before remarked, unusually numerous and excellent. Messrs. Lane & Sons, Berkhamstead, exhibited a collection of sixteen varieties, with three bunches of each. Among them were fine examples of Barbarossa, Trebbiano, Black Prince, Gros Colman, Muscat of Alexandria, Alicante, &c. The same exhibitors also contributed half-a-dozen Vines in pots, which were admirably fruited. They consisted of three of Foster's Seedling, carrying twenty-eight, twenty-seven, and twenty-six large and well-formed bunches respectively; two Black Hamburgs, with fifteen and sixteen bunches; and an Alicante with fourteen. For their exhibits Messrs. Lane were deservedly awarded a gold Knightian medal. Mr. Wildsmith, Heckfield, Winchfield, was awarded a silver Knightian medal for twenty-two bunches in ten varieties. They comprised some excellent examples of high class culture. Amongst the most noteworthy were fine handsome bunches of Gros Colman, Lady Downe's, Alicante, and Alnwick Seedling. The last-mentioned variety deserves a passing note, as it is a variety not often met with. It is supposed to have originated from Alicante and Lady Downe's, and it is considered to be superior to the former and scarcely inferior to the latter in point of quality, while for handsome appearance and finish, it surpasses both. A similar award was made to Mr. Goodacre, Elvaston Castle, Derby, who exhibited a similar collection, consisting of twenty-five bunches, in twelve varieties. These, too, were admirably well grown and exhibited. The best of them were Alicante, Barbarossa, Lady Downe's, Trebbiano, &c. A handsome new variety was shown by Mr. W. Allan, Gunton Park, Norwich. It is the result of a cross between Syrian and Alicante, and appears to partake of the character of both. The bunch is remarkably long and tapering, and the berries are elongate, and appear to finish well. One of the samples shown was grown in a late house, inarched on Lady Downe's, and the other from a Vine on its own roots. A bronze Knightian medal was awarded to this exhibit. Mr. Ross, Welford Park, Newbury, showed five Pineapples of the Smooth Cayenne variety, which were remarkable examples of skilful culture, being of handsome form and fine size. The heaviest weighed 8 lb. 14½ oz., and the lightest 5 lb. 5 oz. A bronze Knightian medal was also awarded to these. Messrs. Veitch exhibited about a hundred varieties of Apples grown in their nursery at Southfield, Fulham. Notwithstanding the unfavourable season some varieties were quite on the average as regards size, but others were decidedly not so. An interesting point in connection with this collection is that all the fruits were taken from trees which, comprising the stock, only ranged from 3 ft. to 6 ft. high. A silver Knightian medal was awarded to these. A similar award was voted to Messrs. W. Paul & Sons for a collection of a hundred dishes of Apples and Pears. A few plants of Osborn's Prolific Fig were exhibited by Messrs. Osborn & Son, Fulham. It is a remarkably productive variety even in a small state, and no doubt will prove especially useful for pot culture, and the fruits are said to be large and finely flavoured.

Two seedling varieties of Shallots were sent by Mr. Pond, Jersey, named Jersey Lily and Jersey Giant Red. Fruits of Melons, Cucumbers, &c., were exhibited by other contributors, and a new purple-top Turnip named Early Munich came from the Society's garden at Chiswick, to which was awarded a first-class certificate.

Unseasonable Flowers.—The late fine weather, in addition to bringing out the ordinary summer bedding plants in better condition than they have ever been before this year, has also brought out quite a display of Primroses, Polyanthus, &c. Cultivation probably alters the season in which these flower, as one seldom finds the real wild wood Primroses flowering except when the days are lengthening.—J. G.

AMERICAN NOTES.

Viburnum nudum.—During July and August our grounds suffer in appearance from the want of shrubs in flower, and anything attractive then is welcomed. This *Viburnum*, though not in flower within these months, is yet most beautiful with its berries. It flowers in June, and after this is soon covered with green berries, hanging often in great clusters. These berries in time turn almost white, then change to rosy-pink, and at last to a deep purple colour. Often the whole of these colours are to be found on the same bunch—one berry changing colour a little in advance of the other. There are other native *Viburnums* valuable in the same way, but none that are as good as this one.

Vanilla Trees.—The delightful fragrance of the flowers of the *Paulownia* has obtained for it the name of "Vanilla tree." The English papers complain of thus robbing the *Vanilla* of its name, but it must be borne in mind that the "Vanilla" did not come by its name honestly. According to De Candolle the *Heliotrope* is the "original" *Vanilla*.

Picea pungens.—Dr. Englemann decides what has been known as *Abies Menziesii* of Colorado, and the *Abies Menziesii* of the Pacific coast, to be two distinct species, and has named the Colorado plant *Picea pungens*. It is to be regretted that this name has been chosen, as, on account of the confusion of generic names that exists among the Coniferae, it is like making two of one kind, as we already have a *Pinus pungens*. It may be as well to repeat that the plants known as *Abies* under botanical rules are *Picea*, and that those known as *Picea* are properly *Abies*. The transposition of these names, begun in error, has been so widely circulated that even botanists have held it hopeless to attempt correction, and have mostly yielded to the wrong. Dr. Englemann believes in always sticking to the right, regardless of success, and this is why he uses *Picea* in speaking of this Spruce.

The Arnold Arboretum at Boston, U.S.—Mr. Meehan gives an account of this which is encouraging for those who do not think that a garden should be arranged as an herbarium or a book. The collection of hardy trees and shrubs for the future Arboretum has already been going on for a few years past, and an immense number have been gathered together, leaving very few desiderata able to endure Boston winters. The grounds for the future Arboretum have been left by will for the purpose, but if a committee had been appointed for the purpose by some learned body to select a site, it is doubtful whether one could be found better suited to the purpose. There is level land, and again land very steep; there are rocks, and hills, and streams, open places and deep shaded woods, grand old trees already there, and vigorous young saplings. In some hands I should fear the great natural beauties might be spoiled by some fancied demands of science. The water Lily and the Tulip tree, the swamp tree and the tree from the high and exposed rocky hill—all would have to be brought into close association, for, behold, are they not found so on some herbarium shelves? But I hope that here they will be put where they will flourish best, and where they will look best; where they will add to the beauty already here, and to the pleasure of thousands in that locality; and that scientific arrangement will be left to the scientific works which, at any rate, the student must study, merely numbering and mapping all, that with guide book in hand the student may readily find what he wants.

Fern Etchings.—Mr. Williamson's book, "Fern Etchings," in which forty-five native Ferns are figured, has just appeared, and proves to be a very beautiful and valuable work. The price is \$7.50—by no means high for pictures of all our Eastern Ferns.

Rondeletia anomala.—This, one of the most beautiful of all summer flowering plants for American flower gardens, Mr. Hemsley identifies as the *Bouvardia strigosa* of "Plante Hartwegiana," or, as Mr. Hemsley now calls it, *Rondeletia strigosa*.

Japan Persimmon Fruiting in California.—Mr. Niles, writes: "I remember an editorial note of yours, which seemed in doubt as to whether the Japan Persimmon had fruited here. It has, and in a number of places over our State. Possibly fifty trees fruited last year, and twice as many this season; but of course they bore only a few specimens apiece."

Two Good Bedding Tea Roses.—Mrs. Melrose, Masz., writes: "I have tried two of the newer Tea Roses this summer—Marie Guillot and Comtesse Riza de Pare—and find them very much superior to the generality of Tea Roses for bedding purposes. They are extremely vigorous in growth, especially the latter, and most profuse in bloom. Marie Guillot is a rich creamy white, and Comtesse Riza de Pare is a peculiar shade of salmon-rose, tinted with copper. It is full, globular in form, and one of the most satisfactory Roses, both in habit and flower, that I have ever used."

The Climbing Hydrangea.—I notice a discussion on the *Schizophragma hydrangeoides*. I hope to send you next summer a photograph of one I know of growing on the Island of Yezo, by which you may judge of its great beauty. Colonel Clark had not the advantage of seeing this plant in full beauty, for he did not arrive here till the end of July, 1876, when the beauty of the plant was over; and, besides, that season was remarkable for drought, when everything suffered here.—**LOUIS BOEHMER, Hokkaido, Japan.**

Lantana Harkett's Perfection.—We saw some plants of this growing out-of-doors this year, and could not help feeling that if it had been an introduction from Europe, instead of an American seedling, it would be in great request for bedding purposes. Its peculiar yellow green tint of foliage would harmonise well with many bright colours in a mosaic bed. As a greenhouse plant it is not a success. In early spring especially, when among other plants, it has a sort of red-spiderly look, which may excuse one in passing it over; but out-of-doors, as we saw it the past summer, it passes out of this defect and becomes a perfect gem.

Zinc Labels with Lead Pencil Writing.—I can show you such labels made and written upon with common lead pencils as much as eight years ago, and if you visit my garden, you will find many such labels fastened to *Gladiolus*, *Rose*, and other stakes. They are cheap and durable, lasting a lifetime, if cared for. I find many gardens and fruit grounds entirely devoid of labels, and others marked by a piece of shingle or stake, written on with pencil. These, as every one knows who has tried them, are very unreliable, as they soon break down or the writing becomes obliterated. I go to the tin shop, obtain some waste pieces of zinc, cut them into strips about 2½ in. long and ¼ in. to ⅜ in. wide, punch a small hole near one end; purchase a few yards of copper wire—ordinary bell wire—cut it into pieces about 6 in. long, put a piece of the wire in each piece of the zinc, give it a twist—and my label is prepared ready for use. I keep a box of such ready whenever needed. I think every one who will try the zinc label will for ever after discard wood, and those who have never labelled their trees and plants will be highly gratified with the experiment, and will ever after adopt the plan.—*Gardener's Monthly.*

The Beauty of Hebron Potato.—Owing to the favourable reports read during the season of 1878, I concluded to plant a barrel of this variety of Potato last spring. I selected a Clover sod, ploughed about 9 in. deep, gave it a good covering of barn-yard manure, and harrowed it in—soil, a gravelly loam. The Potatoes, cut to one and two eyes, were planted on April 15th, in hills 3 ft. apart, two pieces to the hill. At the same time I planted in the same field Early Rose Potatoes of medium size, cut lengthwise, two pieces to the hill. Thorough cultivation and two hoeings were given to both, and the weeds were pulled late in the season. Results—the Beauty of Hebron came up three days before the Rose with stalks strong and vigorous. The tops died and the tubers matured at least ten days before those of the Rose, while the yield from ninety-eight hills of each was about a peck more of Beauties than of Roses. The tubers, too, were larger, smoother, and more salable. I am offered 45 cents per bushel for the Rose and I dol. per bushel for the Beauty.—*Rural New Yorker.*

Hydrangea paniculata grandiflora as a Standard.—A good deal is said now-a-days about the attractiveness of the standard form of this *Hydrangea*; or, in other words, people fancy that its great trusses must be specially fine, erected on a stem or standard, for very few have ever seen a really standard *Hydrangea*. The oddity of the form doubtless constitutes one of its attractions; but another may be certainly found in the fact that this form of growth brings out the effect of the flowers more prominently. It prevents likewise both foliage and flowers from being trailed and beaten into the ground. One objection made against the standard form is the crooked shape the stem generally insists on assuming. Viewed in another way, moreover, the standard form is unnatural—not adapted to exhibit the true habit of the plant grown under favourable conditions. If, therefore, standards are employed at all, a short or low stem should be accepted as the most practical and appropriate to the so-called Tree *Hydrangea paniculata grandiflora*.—*Country Gentleman.*

The Sorrel Tree.—This handsome shrub or tree (*Oxydendron arboreum*) is found wild in rich woods in Pennsylvania to Ohio and southwards along the Alleghanies, where it grows from 12 ft. to 40 ft. high. It is not generally considered very hardy so far north as Boston, but in the garden here are several bushes of it, some in open places and others in shrubby clumps, and they grow unscathed. About the middle of July every branchlet is terminated by a loose cluster of one-sided racemes of white flowers, that last in fair condition into August. The leaves, too, assume a gold and crimson colouring in the autumn. Notwithstanding the highly ornamented character of this plant, it is hardly ever found in private gardens;

indeed, only a few nurserymen have specimens for sale. Professor Sargent tells us that at the Arnold Arboretum they have found it rather difficult to propagate—the seedlings die off unaccountably.

Sarracenia purpurea.—Our common Pitcher plant, Side-Saddle flower, Huntsmans' Cup, Whipperwill's Shoe, as it is variously called (*Sarracenia purpurea*), is advertised in England as having "withstood the severity of the late winter." As this plant is found in the Hudson's Bay region, we do not in the least doubt it.—*American Agriculturist.*

ANSWERS TO CORRESPONDENTS.

Furnishing Back Wall of Vinery.—What will be most profitable, fruit or flowers, to grow on the back wall of my Vinery, the height of which is 12 ft.? It is a lean-to, with an east aspect, and I shall force a little with hot water when the Vines are established.—**AMATEUR.** [There are few things amongst either fruits or flowers that will succeed well on the back wall of a Vinery after the glass roof is well furnished. Probably the most profitable plant to grow there would be the double white *Camellia*. Large plants of it might be planted in the border and be trained to the back wall, or, better still, grow them in large tubs to be placed out-of-doors for a time after the buds are set.—**J. D.]**

Tubers of *Boussingaultia baselloides* Eatable.—Can you tell me whether the tubers of this are eatable? and, if so, how they should be cooked? for the plant thrives here and the tubers increase at a surprising rate.—**S** [We see no reason why the tubers in question should not be edible, considering that those of *Ullucus tuberosus* are constantly eaten in Bolivia and Peru. So far as the mode of cooking is concerned, boiling is, of course, the most simple. Alternate steeping and freezing, as practised with the native Potato, is perhaps the best way to prepare these waxy tubers for the table. Such treatment reduces their waxiness, but the process involves too much trouble.—**J. R. J.]**

Fern Insects.—My Ferns have suffered much from the enclosed insects. Would you kindly inform me what they are, and how best to get rid of them?—**A. S.** [The insects which have attacked your Ferns are a species of plant bug (*Bryocorus pteridis*) which is often abundant on the common Brake Fern. It injures the Ferns by puncturing their fronds with its proboscis, and sucking the juices. I should try Tobacco smoke, or shaking the plants over a sheet or tank of water, destroying the insects which have been shaken off.—**G. S. S.]**

Dæmonorops perianthum.—This is getting very yellow and delicate in my ordinary stove house, the temperature of which is from 50° to 74°. Would it do better in my conservatory?—**AMATEUR.** [If the plant is pot-bound or has been subjected to the temperature you state for some time past, its sickly appearance is probably owing to want of heat or root accommodation. Being a native of Sumatra, it requires a regular temperature of not less than 70°, combined with a moist atmosphere; a rise of from 5° to 10° above this would be beneficial, but a temperature below 60° is decidedly injurious. For the present give it the warmest place in your stove, and there let it remain until spring, when, if you find that it requires more pot room, repot it into a size larger pot, taking care not to disturb the matrix of roots formed at the base amongst the drainage, as no class of Palms suffer more from injury to the roots as the genus *Dæmonorops* and the allied genus *Calamus*. If, on the other hand, your plant has been over-potted, and the soil has got into a sour condition, on no account reduce the ball of soil into which the roots have penetrated; the only remedy in this case will be to regulate the drainage and loosen the surface soil.—**C. M.]**

W. S. C.—Your seedling Carnations are, like those you sent previously, good border flowers and well worth keeping.

P. J. W.—The leaves you sent have been attacked by the Celery fly, a description of which will be found at page 229 of the present volume of THE GARDEN.

Fruits.—**C. D.**—Pears: 1, Marie Louise; 2, Duchesse d'Angoulême; 3, Beurré Superfin.—**Pomona.**—1, Beurré d'Areberg; 2, Hesse.—**R. S. T.**—1, Blenheim Pippin; 2, Cox's Pomona; 3, apparently Cockle's Pippin; 4, Golden Pippin Apples.

Names of Plants.—**H. J. E.**—1, *Athyrium Filix-femina gracile*; 2, *Asplenium lucidum*; 3, *Adiantum Capillus-veneris*; 4, *Pteris serrulata*; 5, *Adiantum Warneri* (decorum). **T. S.**—*Escallonia illinita*. **Soursop.**—*Ipomea bonariensis*. **W. H. M.**—1, *Camptosorus rhizophyllus*; 2, *Asplenium Trichomanes anceps*. **Devon.**—We cannot name from leaves only. **Villager.**—*Eryonimus europæus*. **R. J.**—1, *Abutilon vexillarium*; 2, Cannot name without flowers; 3, *Witsenia corymbosa*; 4, *Echites picta*. **E. L., Bourne-mouth.**—*Polygonum Persicaria*, a hardy annual. **M. N.**—Probably a species of *Convolvulus*. **Anon.**—1, *Actæa rubra*; 2, *Jasminum officinale*, var. *B. S. O.*—*Cotoneaster Simonsi*. **C. F. Naas.**—1, *Gilia liniflora*; 2, *Salpiglossis sinuata*. **F. R. J.**—1, *Polygonum amplexicaule*; 2, *Impatiens glandulifera*. **C. B. K.**—1, *Selaginella Mertensi*; 2 and 3, *S. Kraussiana*; 4, *S. Kraussiana variegata*; 5, *Sedum ochroleucum*; 6, Next week. **J. M.**—1, *Senecio sarracenicus*; 2, *Rudbeckia speciosa*; 3, *Anemone japonica*. **J. W.**—1, *Pereskia aculeata*; 2, *Bupleurum fruticosum*; 3, *Pyrethrum niginosum*; 5, *Helianthus multiflorus* fl. pl.—**Florist.**—The flowers you send cannot be named except by a specialist.—**Amateur.**—1, *Lygodium scandens*; 2, *Adiantum tenerum*; 3, *Asplenium bulbiferum*; 4, *Lindsea cultrata*.

Questions.

Rabbits and Lawson's Cypress.—As rabbits do not touch this kind of Conifer here, do they show their aversion to it in other places.—**R.**

Cracked Pears.—I send you a specimen of Pears taken from two trees which are growing in close proximity one to the other. There are only about half-a-dozen good fruit on them, the remainder being all cracked and as hard as those sent. On another tree a few yards from these the bulk of the fruit is good and a few only are cracked. The trees are espaliers, and stand about four or five yards from a pond; they are quite open to the south. Can any of your readers oblige me with any information as to the cause, and suggest a remedy?—**RYDAL MOUNT.**

Coarse-growing Grasses in Ponds.—I have a pond about three quarters of an acre in extent, which, having been neglected for two or three years, has become quite filled with a coarse Grass which grows so thickly that the water is scarcely visible and other aquatic plants are smothered. Can any of your readers suggest a mode of eradicating this Grass.—**WATER LILY.**

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

TREE PLANTING A PROFITABLE INVESTMENT.

IN confirmation of the truth of the remarks upon this subject which appeared in the last number of *THE GARDEN* (p. 342) I will submit for the consideration of landed proprietors and others interested in the subject a few facts and figures, the truth of which may be verified by an examination of the wood books of this estate—Surrenden-Dering. If ever there was a time in the country's history when strong inducements to plant trees were offered to the owners of suitable lands it is the present, when, owing to a succession of bad harvests, and to other causes beyond our control, much of the heavy land of the country is likely to go altogether out of cultivation or be thrown upon the hands of its owners. The employment of a portion of the agricultural population of the country during the coming winter in reclaiming, draining, and planting such land would confer an immediate benefit upon the labourers themselves, for whom employment will be scarce.

These woodlands are situated partly upon hills of Kentish ragstone, where the soil is friable and of fair quality, and where the plantations partake of the nature of "lews," as they are called in Kent, or shelter belts of various widths. Most of these narrow strips were originally planted to shelter the homesteads and the Hop gardens, as well as the arable and pasture lands, from the west and north-west winds, which often do considerable damage; but the greater part of the woodlands are upon the Wealden clay, which, during a wet season, is one of the heaviest and most unworkable in the kingdom.

Nearly all the woods are worked in rotation, either as pure coppice, or as coppice with standards, and cut at periods varying from nine to thirteen years, according to the soil and the kind of wood grown. Some of them may be described as natural woods, of which the value has been considerably enhanced by cutting good open ditches at intervals proportioned to the slope of the ground and the retentiveness of the soil, and by planting up vacant spaces after every fall. Others are regular plantations of Ash, Sweet Chestnut, Birch, Willow, &c., either distinct or in combination, which are laid out in sections or beds separated by good and deep open ditches. The older woods consist largely of Oak, Hornbeam, Birch, Willow, and Hazel. Every year a considerable acreage is laid out into "cesses," which are again sub-divided into "cants," containing from three to six rods each, and sold by public auction early in November. One advantage of small lots is that many of them are bought by the agricultural labourers, who from small beginnings are now able to pay down in the sale room their deposits, amounting in some cases to from £50 to £60 per man. These purchasers work up their own lots, selling the produce to the Hop-growers, lime-burners, and cottagers. Half the purchase money is paid down at the time of sale, and for the other half they obtain credit for a year, giving proper security if required. In the mixed coppices about thirty tillars per acre are reserved by the proprietor, as well as the whole of the standards. The latter are afterwards thinned out during the winter, or—if consisting of Oak—as soon as the bark will run in the spring, by the proprietor's own men, and then carted into convenient lots and sold by auction in June or July. Much of the land upon which these plantations are made was not worth an agricultural rent of more than 7s. per acre.

As a preparation for planting, the land was ploughed to a depth of 10 in. or 12 in. at a cost of about £2 per acre. Some parts were trenched to a depth of 16 in. or 18 in., at a cost of £5 or £6 per acre. With our present advantages of steam cultivation we can considerably lessen the cost of preparation, which of late years reached as much as from £8 to £9 per acre. The first of these plantations was made about forty-five years ago, and at the present time they show no signs of diminishing in annual value, the Ash, Chestnut, and other stools being still vigorous.

The original total cost per acre upon small plantations was unnecessarily high, being for enclosing, ploughing, and afterwards trenching, draining, plants and planting, cutting back the trees at the end of the second year, and afterwards digging well between them, as much as £15 per acre.

For the sales made in 1865, when the prices obtained for produce in Hop-poles, &c., were not nearly as high as they have since been, the books show the following returns: For the Weald or low hill woods of twelve years' growth, £40 8s. per acre, including the thinnings of standards, a certain proportion of which come down every

fall. Upon the same soil, coppice or underwood only, £25 per acre for twelve years' growth. The sales of the woods upon the Hill realised £41 7s. per acre for eleven years' growth. The income from the Uplands is probably not more under wood than they would realise as arable lands; but the benefits these belts and small plantations confer upon adjoining lands must not be lost sight of in estimating their value as part of the estate.

Much higher prices than the above have been made of small lots. In 1865 one of these made £57 per acre for ten years' growth, and 100 square perches sold for £45. Another lot of 100 square perches which sold for £28 2s. 6d., turned out the following materials which sold at the annexed prices:—

300 10-ft. Hop-poles at 6s. per hundred	£0 18 0
400 12-ft. "	12s.	"	...	2 8 0
800 14-ft. "	23s.	"	...	9 4 0
800 16-ft. "	30s.	"	...	12 0 0
500 25-ft. use-poles "	33s.	"	...	8 15 0
50 Household faggots at 20s.	"	"	...	0 10 0
400 Brush faggots, adapted for lime or brick burning at 5s. per hundred	1 0 0
Total				£34 15 0

The expenses of falling and working up this lot were £2 10s., thus leaving a clear profit to the purchaser of £4 2s. 6d.

To ensure profitable plantations the first outlay upon these heavy lands is considerable; but upon hillsides, heaths, and such situations as are generally chosen for the planter's operations, where small plants are notched in or larger ones are pitted, and no draining or previous cultivation is required beyond a preliminary clearance which often pays for the expenditure, the outlay is generally confined to the purchase of trees and the expenses of notching-in or pitting and planting. An active man and a boy may plant by the system of notching from 1,000 to 1,300 plants per day. Upon our heaviest soils we pay 1s. per 100 for holes 10 in. deep by 18 in. across; and supposing the plants to be put in 4 ft. apart or 2722 to the acre, the holing will cost £1 7s. 3d. Plants from 18 in. to 24 in. in length may be bought for about £2 per 1000, or £5 8s. 6d. per acre. Add to this the expenses of planting—say, 12s. per acre—and we get a total of £7 7s. 9d. per acre. Where smaller plants can be notched in, the total expense need not exceed 80s. per acre.

To show the advantages of regular plantations over the natural growth from the old and neglected stools, I might quote figures before me which prove conclusively that in years when the former have realised £25 per acre the latter have made only £14 6s. for the same number of year's growth.

Upon nearly every farm and certainly upon every estate in the kingdom, there are neglected pieces of land which would pay well for planting with trees, while they are almost useless for other purposes, such as odd corners of fields, roadsides, river margins, rocky slopes, barren heaths, and low-lying swampy grounds. Upon some of the latter the roots of Poplars have been found to penetrate deep enough to open up the substratum and permit the waters to drain off. All that is required at the present time to confer an inestimable boon upon both the agricultural population and the landed proprietors is a little enterprise, judgment in selecting trees and laying out land, and care in the planting. Thus we may tide over a time of trial and great depression and confer upon the country generally an advantage which will become more apparent every succeeding year.

A. J. BURROWS.

THE OLD OAKS AT THORESBY.

THESE, the remnants of "Merrie Sherwood," constitute one of the features of greatest interest at Thoresby. They may be counted by thousands—trees perhaps 1200 years old, of wonderfully large girth, some of them stag-headed with great excrecences here and there on their massive trunks; but some of them symmetrical with spreading heads and limbs of enormous size. One of the largest of them is the "Major Oak," still a magnificent tree, of which a representation will be found in *THE GARDEN* (Vol. IX, p. 492). Its trunk, which is hollow and capable of holding some ten or twelve people, measures, at 2 ft. above the base, 32 ft. in circumference, and at 4 ft. from the ground 29 ft. This tree is annually visited by hundreds of people from all parts of the country and especially by artists, who are fond of sketching it as well as other denizens of this ancient forest. Of this tree there is a wood carving by Robinson, of Newcastle, over the fire-place in the library at Thoresby with red and fallow deer browsing amongst the Fern beneath its branches, and below it figures of Robin Hood and Little John. Next perhaps in size is an Oak called the "Simon Foster," a tree little inferior to the "Major," and one equally an object of

a admiration. It measures, at 2 ft. from the ground, 31 ft. 6 in., and at 4 ft. up, 25 ft. Then there is the Shambles Oak also in this district, a tree so named from its hollow trunk having been made a butcher's shop, so to speak, in which were hung up and "dressed" the sheep and deer killed in the neighbouring forest by those who, in times past, set property rights at defiance. This, when a "hale green tree," must have been one of enormous size, but one half of it is now gone—in short, it is a mere shell, some boys having set it on fire some four or five years ago while burning a wasp's nest in its centre. One more remarkable tree is the "Parliament Oak," so named because under its once spreading branches King John, who had a palace not far off, held a parliament. This is now a complete wreck, the few leafy branches of which its head consists being supported on props. Nor must I forget while in this part of the country the "Greendale Oak" at Welbeck, a tree with an opening in its trunk through which a coach might be driven. This aperture measures rather more than 6 ft. wide, therefore some idea of the size of the trunk may be formed. Few of these old Oaks are, however, now to be found at Welbeck, and therefore those who wish to see these storm-tossed veterans of ancient Sherwood must visit Thoresby, where they cover hundreds of acres and where, thanks to the liberality of Lord Manvers, they are as open to all who care to see them as "Burnham Beeches." Mr. Jamieson, Lord Manvers' forester, informed me that few, if any, of these old Oaks are wholly sound although the young wood produced by them is surprising, and that accidents have even occurred from the sudden breakage of some of their huge and high poised limbs. Young plantations of fine Oaks, properly thinned and otherwise well cared for, are, however, plentifully dispersed over the Thoresby estate, and these will, at no very distant date, take the place of the old trees now showing in most cases unmistakably the evil effects of that fell destroyer—Time. M.

EFFECTIVE COMBINATIONS IN PLANTING.

A WRITER of the last generation draws attention to the charming contrast furnished by the near association of the deep green foliage of the Laurel with the graceful, drooping, waving branches of the silver-barked Birch, the weeping variety especially; rising out of a ground-work of Laurels, Rhododendrons, or other large-leaved evergreens, they always produce a striking effect, especially in winter. But the evergreen undergrowth should not be permitted to grow so tall as to hide the trunks of the trees, as when this happens much of the intended effect is lost, and the undergrowth soon becomes naked at the bottom and unsightly. The best way to manage low underwood of this fast-growing character is to prune it annually—not hard in, but to cut back runaway shoots, as these are the leaders that carry directly upward the strength of the plants, which results in a wasted base. With a little attention every winter or early in spring the undergrowth may be kept in good condition, and always look well, forming a beautiful frame to the tree picture, and which may be arranged either to harmonise or contrast by a careful selection of the materials employed. I have often thought that, in the arrangement of new plantations, hardly sufficient importance is attached to their winter aspects and effect. And yet it is in winter, when the skies are often covered with leaden clouds, and when out-of-door aspects are of a gloomy character, that the mind is peculiarly open to receive pleasing impressions from the contemplation of tree vegetation, because at that season there is so little else to interest and arouse attention. It is true that, in most instances, the grounds near the house are generally well furnished with evergreens, not only with the view of securing shelter, but also of making a pleasant picturesqueness; and I think, so far as both objects are concerned, their attainment is not incompatible with a judicious use of deciduous trees and shrubs. We all know how the force of the fiercest wind is broken by a thick Thorn or Beech hedge in winter, when the leaves have mostly fallen; the cold current is grasped in the thick folds of the hedge, and dispersed on the other side in the gentlest zephyrs. In fact, no evergreen can grapple with a strong wind in the same manner as a stout Thorn fence does, so far as concerns calming down and mitigating its injurious force. Then, again, in the annual change of dress, deciduous trees and shrubs have a decided advantage over evergreens, though I am not forgetting the beautiful tints assumed by the young growths of the Box and Yew trees, and many others of a similar character, in spring; but they will not compare with the ever-varying foliage of trees of a deciduous habit. There are numbers of large old Elms of various kinds near where I am writing, and it is so pleasant to note the daily change in spring and autumn, when they are putting on and shedding their leaves. But when they are about half dressed in spring is the time when the effect seems most pleasing, as then their huge limbs can be traced through the cloud of greenish, golden-tinted drapery; and when the sun shines upon them the whole looks like a

fairy scene. It is, therefore, very desirable to plant deciduous subjects freely among the evergreens, both in distinct groups and also in the form of single specimens. But I think the best effect is produced by groups of deciduous trees or shrubs when springing out of a base of evergreens, as then, in winter, the whole surface is covered; there is no bare earth visible, and the whole has a thoroughly finished appearance.

Let me give an illustration or two by way of explanation. The *Ailantus glandulosa* is a very effective shrub in summer, if not too much crowded, so that its long pinnate leaves can have room for development; but when denuded of its foliage in winter, it puts one in mind of a room without furniture; there is little or nothing for the eye to rest upon. But plant underneath these bare stems some dwarf, close-growing, evergreen shrubs, and a combination is created that is always very pleasing. Rosemary is sometimes used for this purpose, and a very charming effect it has, either when close under the eye or at a distance from the point of view. Lilacs, Syringas, and the Guelder Rose always look well springing out of a bed of evergreens; as do also Thorns and Laburnums. The common Savin, in a low dark mass, with taller, lighter foliage plants growing out of it, has a very striking effect, and such contrasts always arrest attention. Hollies on a base of St. John's-wort (*Hypericum calycinum*) have a finished look, whether the Hollies be large or small, as the ground is all furnished, and so the arrangement does not lack completeness, and it shortens the period one has to wait for the plants to fill up and hide the bare earth. But this *Hypericum* is rather a strong-rooting plant, and requires to be kept within bounds, which can be accomplished in most soils by mowing it off every spring. This plan of filling-up between specimen shrubs or trees with a dwarf contrasting plant, does away with the necessity of planting many masses, except a few on the windward side. There is a good deal of protective power in low, close-growing plants; they stop the rush of cold currents near the surface of the ground, and shelter and protect the collar of the delicate plant, which is the most vital part. I am acquainted with a garden where there is a sloping bank forming a foreground to a group of deciduous trees. It is planted with specimen shrubs of various kinds, each having space sufficient to show its true character; whilst among the shrubs, completely covering all bare earth, is planted *Vinca major* or large *Periwinkle*. This bank always presents a tasteful finished appearance, which every year seems to increase in interest, as the plants assume their true characters. The *Periwinkles* are trimmed up in spring with the shears after they have completed their flowering, which is generally towards the end of April; the new growth breaks away directly, and the spaces between the shrubs are furnished with a delightful carpet, that has none of the formality of carpets generally, but a light free growth of a pleasing character. The thick growth effectually keeps down weeds, and conceals falling leaves and other debris of autumn and winter. E. H.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Trees and Shrubs in Vienna.—*Mandschurian Dimorphanthus* (*D. mandschuricus*).—This handsome broad pinnate-leaved shrub is very striking, and much resembles *Aralia spinosa*, but is decidedly hardier. It has a great advantage for the climate of this part of Austria. *Crategus Crus-galli* is a tree which never looks better than in autumn, when laden with its scarlet fruits, resembling minute Apples. They help to break up the monotony at this time of the year, when gardens begin to be dull. A tree of *Paulownia imperialis*, over 40 ft. high and as much through, is bearing a mass of fruits.—L. KROPATSCH, *Laxenberg*.

Leycesteria formosa.—This old-fashioned flowering shrub is well worth a place in the most select collection. Its pendulous, Grape-like clusters of bright chocolate-coloured berries impart to it a very distinct and highly ornamental appearance. It produces an excellent effect when growing amongst evergreen and deciduous shrubs, and would also form an admirable subject for pot culture. Although it requires to attain several feet in height before it fully displays its decorative capabilities, it will at the same time flower in a dwarf state, and might therefore be utilised during the autumn and early winter months—a time when it is often found difficult to secure variety for conservatory decoration. It is, unfortunately, of a somewhat tender nature, and, when grown in open exposed localities is liable to be cut down in severe winters; and it is probably owing to this fact that this old inhabitant of our gardens is seldom seen in thoroughly good condition, and that its culture has become neglected. Its merits, however, entitle it to the consideration of planters, and render it worthy of some pains being taken to ensure it against injury from frost. A few evergreen boughs, or two or three old mats, would afford the necessary protection.—J. CORN HILL.

Portugal Laurel Hedges.—In a large nursery in this neighbourhood devoted to the culture of hardy plants, shelter hedges, composed of Portuguese Laurel, are extensively employed. On the north side the hedges are some 4 ft. to 5 ft. in height, and are flanked at intervals by others, which slope gradually to the ground, thus enclosing spaces effectually sheltered from cutting and rough winds, but which are at the same time open to the influence of the sun's rays. These sheltered spaces are used for planting out seedlings, rooted cuttings, or anything which may need some nursing, or would be benefited by protection in the earlier stages of growth. Sheltered spaces such as these are easily formed, and would be found extremely useful for many purposes, such as raising early saladings, forwarding Strawberries, &c. Or were the enclosures made to face the north, they might be profitably utilised during the hot summer months for planting out Primroses, Violets, &c., or screening pot plants against the glare of a hot sun. The Portuguese Laurel would appear to be well adapted for this purpose, as it quickly forms a dense, impenetrable mass of foliage, impervious to the harsh drying winds, which often exercise a pernicious influence upon such plants as have not attained sufficient strength to withstand them.—**J. CORNHILL.**

The Size and Age of Trees.—In reference to this matter Mr. Vernon Heath writes to the *Times* as follows: May I appeal, through your columns, to those who write upon the size of trees to supplement their information, whenever it can be done, with that which is known of their age, because I venture to think that the majority of readers would be more impressed by the fact that a tree had lived several centuries than by knowing merely its girth and height in feet? This leads me once again to speak of some old friends of mine—Burnham Beeches. Who is there in this tree-loving country can tell us something that can be depended upon as to their age? I have sought long and diligently to discover some historical account of them, but have found only that which is vague, legendary, and unsatisfactory. Of their origin there is nothing whatever to be learnt. Who, then, of those who have made tree life their study, will volunteer information upon a subject which, from enquiries I constantly receive, will, I am sure, be interesting to a number of your readers?

THE INDOOR GARDEN.

DECORATIVE PLANTS OF DIFFERENT HABITS.

It is generally acknowledged that the best effect obtainable with any assemblage of plants, either in the open air or indoors, is most satisfactorily secured by having as much diversity as possible, not only in the form, colour, and general character of the flowers which they produce, but still more so in the natural habit of the plants themselves. I repeat natural habit, for a great deal is continuously said and written about the formal appearance of many pot-grown subjects; and objection is taken to their broad, bushy rounded outline, which is charged to a mistake in the training, when all that has been done in that direction has only given them a symmetry of outline such as they would have had if growing in their native habitats with sufficient space and opportunity for full development. I am not taking into account the distortion sometimes practised in plant training, of which no one can approve, but the tying that is necessary to fully open out and sufficiently separate the branches of any specimen, large or small, to admit of the requisite air and light getting to the interior of the plant, for the double purpose of keeping the shoots from being drawn up, and also with a view to allow enough room for the flowers to be seen distinctly. This much, plants that are naturally of a bushy habit, require, whether the specimens are large or small, for it is well to recollect that even under the best possible system of cultivation in the best constructed light houses, the branches of plants in general have a much greater determination to become elongated than when grown uncrowded in the open air. For a very long time after glass erections were devised for the cultivation of plants too tender for growing out-of-doors, they were little better than receptacles for weak, branchless starvelings, the result of overcrowding and a manifest absence of perception as to their requirements. Of this state of matters we have abundant evidence, as, even within the last thirty years, the above description would hold good with the greater number of plant houses throughout the country. When exhibitions of plants in a better developed condition came into fashion there was a disposition to adopt a different form in the subjects grown—the opposite of the tall spare examples that had so long done duty in greenhouses and conservatories, the result being that most of the plants now-a-days have a bush-like shape, with comparatively little to relieve the even

monotonous surface. Frequently, indeed, do we see whole houses in which everything is rejected that cannot be made to conform to such a form of growth. The consequence is that although the plants, from a more liberal course of treatment, are capable of producing a much greater quantity of flowers, still the monotony in form is objectionable. In spring we find stages full of Primulas, Cinerarias, Cytisuses, Azaleas, zonal Pelargoniums, forced shrubs, and bulbs, the tallest furthest from the eye, with the smallest in front, coming down in a gradual even descent. These are succeeded again by Fuchsias, self and fancy Pelargoniums, Calceolarias, and others of a like character and habit. An attempt to relieve such is frequently made by growing some or other of the preceding plants in the form of standards, the outcome of which is that the broad bushy heads are removed above the pots, breaking the otherwise level surface, but nothing more; whereas if subjects of a totally different character had been chosen for intermixture the arrangement would have been much more satisfactory.

This objectionable state of affairs does not so often exist in warm stoves and conservatories, where the generally cultivated fine-leaved plants are usually found, as it does in the cooler greenhouses to which I am more particularly alluding, and from which even such plants as the old-fashioned *Humea elegans* are almost banished, although its tall erect stem, furnished with graceful drooping branches, renders it so fitting a subject for giving the desired contrast to the other compact-habited plants. Yet it is by no means to want of materials in the shape of plants of a character somewhat similar to the *Humea* to which the absence of artistic effect in the furnishing of greenhouses can be attributed, but a too common absence of perception that, however well grown, according to their kind, the subjects employed may be, a tasteful and pleasing arrangement is impossible without sufficient diversity in the form of the plants forming the whole. It is in this matter of choosing the plants best calculated for effective combination in grouping that the Continental gardeners excel, as those who have had an opportunity of seeing their exhibitions can testify, though the plants in themselves are far from showing the skill in cultivation usually met with at similar gatherings at home. We are often led away too far by the appearance of plants individually, their rarity, or their being new, losing sight of the important fact that fitness for the purpose required is indispensable for any assemblage of plants, as much in the home grouping as in an exhibition. Amongst flowering subjects, such plants as *Habrothamnus elegans*, *Nerium*, *Erythrina*, *Campanula pyramidalis*, *Clanthus*, *Abutilons*, *Hedychiums*, *Acacias*, *Lilies*, and others of a like character, confined to single stems, or mostly so, with the number of handsome-leaved plants, like the less tender kinds of *Draenas*, *Grevilleas*, *Lomatias*, *Rhopals*, *Yuccas*, *Aralias*, and *Cannas*, each grown to one stem; the green and variegated forms of *Phormium tenax*, kept to single crowns; the useful *Humea elegans*, of which a supply can so easily be maintained by sowing a little seed each year—these and others that will occur to the cultivator, if fairly managed, will afford all the year round abundant material wherewith to furnish a greenhouse, large or small, in a way to make the whole arrangement such as to satisfy those who look for something beyond the plants individually, without materially interfering with the general well-being of the lower-growing portion, which, as a matter of course, will exist in greater numbers than the taller plants.

Most of the above, when they get too tall or deficient of leaves, will bear heading down, and thus can be renewed; and the majority with the aid of liquid stimulants, can be kept in a healthy condition without the use of large pots, and admit of being further employed for hall or room decoration when occasion requires.

T. BAINES.

BOUVDIAS ON THE COOL SYSTEM.

I SEE (p. 352) that Mr. Baines still advocates a brisk heat, and therefore expensive treatment for these lovely winter-flowering plants. We are better pleased with our *Bouvardia* plants this year than we have been for many seasons; indeed, we never had them in better condition. Owing to the season being so unfavorable, they were not planted out this summer, but were grown on in pots in a cool house and in frames. About a month ago some of the plants were removed into a briskly-heated pit, and others were placed in a Vinery, from which all the fruit had been cut, and which is now freely ventilated night and day. Those in the Vinery are looking equally well, and producing as many flowers as those in the heated pit; and judging from past experience, those under cool treatment will do equally well as those in heat. My daily experience of *Bouvardias* is that their blooming does not depend so much on the heat which they receive as upon good culture. Well grown plants will bloom freely and well for the greater part of the winter if kept clean, and in an ordinary greenhouse temperature, say from 45° to 55°. Perhaps many amateurs grow the septants fairly well in frames in summer

and the greenhouse in winter; and to such as have not already tried them, I would say begin at once. Do not let the want of brisk heat deter you. Plants which will make your greenhouses gay, and supply you with cut flowers such as could not possibly be surpassed, will be your reward; and the same treatment which causes *Cinerarias* to grow and flower freely will be found to suit *Bouvardias* admirably. I am glad to see that Mr. Gilbert takes the most useful and generally applicable way of treating his *Bouvardias*, and places them "in the greenhouse to flower."

CAMBRIAN.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Training and Tying Plants.—If "Consistent," who criticises what I have had to say on this subject (p. 304), cannot see the difference between the training of *Chrysanthemums* or *Pelargoniums* in the objectionable Mushroom-like form we so often see them, from 3 ft. to 5 ft. across, and not more than 10 in. to 1 ft. high, as compared with the *Heaths*, *Ixoras*, and *Azaleas* tied as nearly to the shape they grow in naturally as their safe carriage to and from the places where they are exhibited admits, then anything I can say in the matter will be useless so far as he is concerned. "Consistent" either ignores or loses sight of what I have always urged in respect to the training of plants for exhibition, for it is to these he particularly alludes, and not to such as are wanted for ordinary decorative purposes, which, as I have pointed out, need no more tying than will give them the requisite support to keep them in something like the form which they naturally assume. So far as my own practise went, when an exhibitor, I may state that I never tied my specimens to the close even surface that many growers, both before and since, have done; and not unfrequently I have had them found fault with by the advocates of formal tying. "Consistent" would be more in conformity with the signature he has chosen had he borne in mind that nearly all our flowering plants (climbers excepted), which are usually used for exhibition purposes, grow naturally as round and formal as a *Mezereon* bush or *Rhododendron*, and the form of training I always adopted, and continue to recommend, has been so much and no more than would keep exhibition plants as near the shape in which they grow naturally as possible—very different from the way in which *Chrysanthemums* and *Pelargoniums* are usually treated as compared with their natural habit of growth.—T. BAINES.

Chinese Primulas in a Cold Frame (p. 337).—It would be unwise to trust Chinese Primulas to the doubtful protection of a cold frame all the winter, especially through such a winter as the last one, as there were periods of frost so severe for three weeks at a stretch, when no daylight could be admitted, and it is easy to imagine what such plants would be like after such confinement; besides, only the thickest of covering could keep severe frost from plants in a cold frame. But there is even a more forcible reason why they should not be wintered in a cold frame. *Primula sinensis* is peculiarly a winter-blooming plant, and to shut it up in a cold frame from November till March would be a great mistake, as in such a place it cannot be seen to advantage if in bloom, as if it does flower it would soon lose all its bloom through damp, to the effects of which it is most susceptible. The best—and, indeed, only suitable—place for Chinese Primulas through the winter is a greenhouse or conservatory, where there is a genial temperature and plenty of light and air. To immerse them in a cold frame all the winter is to consign their beauties to a dungeon. Cold frames, as the designation implies, should be used only for plants that require in summer a cool temperature, and in winter for those that are quite hardy, or not being entirely hardy are somewhat at rest. Even in mild winters, when there is little frost, damp is almost as dangerous to plants as severe weather, especially as most frames are placed or built on the ground, so that the damp of the soil is attracted upward. Those who have no other glass but a cold frame will be well advised not to trust too much tender material to its protection; but hardy plants, such as bulbs, Pansies, Auriculas, Alpine Primulas, Pinks, Carnations, Polyanthuses, and others may be grown in it with the greatest safety, and will cause no anxiety during the hardest weather.—A. D.

Vallota eximia.—This fine variety of *V. purpurea* deserves to be more extensively cultivated than it is, for a more beautiful autumn and winter-flowering bulb is not to be found. Its colour—bright scarlet—renders it a most striking object, both for conservatory and for room decoration, while its cultivation is so simple that any one can grow it. Let some good-sized bulbs be procured now and kept gently growing on through the winter in any glasshouse in a temperature of about 55°. Keep them moderately watered, and set them in a light position, and they will, by next autumn, have made fine large flowering roots; then keep them rather dry for a time, but not sufficiently so to in any way injure the foliage.

Then place a few bulbs at a time in a gentle warmth, and fine large trusses of exquisite scarlet flowers will be the result. They will succeed well in 5-in. or 6-in. pots, and they do not require frequent repotting. The soil best suited to them is good fibry peat and loam in equal proportions, and plenty of silver sand and good drainage. This plant succeeds admirably in the window of a warm light sitting-room, where it cannot fail to be admired by all who are fond of flowers. *Vallotas* are very easily propagated by means of the small bulbs which form freely round the base of the parent roots.—HENRY BAILEY.

Hints Respecting Cyclamens.—Cyclamens still are so generally mismanaged by amateurs that a few hints respecting them may be of use to some who have hitherto not succeeded with their culture. The very first thing to be done is to secure seed of a really good strain; the best way is to purchase plants in flower of the best varieties, and save one's own seed. A visit to say such a collection as that grown by Mr. H. B. Smith, of Ealing, would enable the would-be grower to procure the best strain, and so avoid the inevitable disappointment that attends the growth from inferior seed. It is best to place the plants in their separate colours on a shelf near the glass, and on bright days the pollen can be distributed with a camel's hair brush, which will cause the flowers to set their seed freely. As the pods ripen let the seed be carefully gathered and dried. This is a very good time to sow the seeds, which should be put in pans slightly covered; keep them moderately moist, and place them in a brisk heat. When the seedlings are large enough to handle, prick them off, and as soon as possible pot them into small thumb pots. Shift again into 3-in. pots, and as soon as these are filled with roots move them into their (for this season) blooming pots, viz., 5-in. ones. The best soil for them is good loam and peat, plenty of silver sand, and free drainage. They require to be kept growing freely always in a genial warmth; and, most important of all, they must be kept thoroughly clear of insects. I do not think *Cyclamens* ever recover from an attack of green fly if neglected, hence so many failures. They also require great attention as regards watering; never allow them to become dry. These few simple instructions followed, will, I am sure, be productive of good results.—H. BAILEY.

The Hail Storm Relief Fund.—It has been decided to close this fund on Saturday, November the 2nd, and it is the desire of the committee that any subscriptions not yet sent in may be remitted without delay. At a meeting of the committee held on the 14th inst., the sum of £800 was voted for relief purposes on the recommendation of the investigation committees. When these were appointed, the executive committee, finding that the subscriptions announced represented but a fifth part of the aggregate amount sent in by sufferers, instructed the investigation committees to confine their labours to ascertaining the actual amount of glass broken, specially recommending the most deserving and necessitous cases. These returns having been made, were duly considered in committee, and at a meeting on the 18th inst., the sum of £800 was voted. The aggregate quantity of broken glass was found to be very large, and as the amount at the disposal of the committee would not admit of relief being administered according to a uniform scale, it was resolved to divide the applicants into three classes, according to their needs, the most necessitous to receive 3d. per ft., the next 2d. per ft., and the least needy, 1d. per ft.. Already all applicants classed as necessitous have been relieved, and the remainder of the sum voted will shortly be awarded. The sum remaining over at the close of the fund will be further distributed pro rata among the sufferers, as in the case of the Hail Storm Fund of 1876. A balance sheet will then be struck, and the committee will bring its labours to a close.

Substitutes for Potatoes.—We are threatened with something like a Potato famine, and those who remember the similar disaster in 1846 do not need to be told how grave is now the prospect, with a vastly increased population, and a state of depression in trade which signifies on the part of the masses a great difficulty in providing even the commonest and cheapest necessaries of life. Many and well-intentioned are the suggestions which are being made with the view of providing substitutes for the Potato. The French *haricots blanc* or *flageolets*, Lentils, Rice, Maize, and Oatmeal are the substances which are brought most prominently forward as being fit to replace the favourite tuber. In one respect—the quantity of nitrogen which they contain—they all, but especially the leguminous examples, greatly surpass the Potato as an economical nutriment. But, unfortunately, they are all deficient in antiscorbutic elements. Under a diet of these substances, either alone or with the trifling amount of fresh animal food which is all that tens of thousands of persons can obtain, scurvy would be as rife as it was in Ireland and North Britain in 1846–47. Nevertheless all these foods are very valuable, and it only needs that the particular point in which they fail should be recognised and supplemented. If this be not done disease must ensue, and the nutriment fall into disfavour. Any of these sub-

stances may be used with advantage where either an abundance of milk forms part of the dietary, or the antiscorbutic element can be furnished by fresh green vegetables, Onions, or the juice of Oranges or Lemons.—*Lancet*.

THE FLOWER GARDEN.

GENTIANA AFFINIS.

THE Gentians comprise some of our most brilliant hardy flowering plants, the majority of which are natives of Europe. There are but few that have been derived from the Western Hemisphere, though

Gentiana affinis (flowers blue).

in point of beauty of colour there are many, especially in South America, that quite surpass the cultivated kinds. *G. affinis*, which is represented in the accompanying woodcut, is a native of California, where it inhabits very high elevations on the north-eastern parts of Sierra Nevada and other neighbouring localities. It grows from 1 ft. to 2 ft. high; the leafy flower stems bear a profusion of flowers, which are about 1 in. long, and of an intense blue colour. It has flowered at Tottenham this year in Mr. Ware's nursery, from which the specimens our illustration was prepared from were supplied. Another Californian Gentian, that has been introduced, is *G. Newberryi*, a very dwarf growing kind, with pale blue and greenish dotted flowers. Some of the other kinds found there are

very beautiful, and would be desirable acquisitions if introduced. Amongst these are *G. acuta*, *simplex*, *serrata*, *calycosa*, *setigera*, and *sceptrum*, all with flowers of a more or less intense blue colour, and which would doubtless all thrive under the conditions generally accorded to Gentians. W. G.

TULIPS OF THE FLORISTS' CLASS.

How many living within the circle of the metropolitan district will, next November, plant their beds of Tulips? Alas, we fear the answer will be—not one. Tulip devotees about London appear to have died out. The area of the cultivation of the Show Tulip has become much circumscribed in the south of late, but perhaps, ere long, a reaction will come and this showy flower be again grown as it was years ago. I have known an excellent Tulip soil made out of three parts fibrous loam, and two parts top spit from a kitchen garden quarter that had been well worked for many years. This last was employed to act as a slight stimulus, and, being of a light friable character, assisted to render the mixture open, and so ensure a free access of air to the mass. It was once remarked by an old florist that "the great secret of successful cultivation of all plants consists in subjecting the soil in which they are grown to atmospheric influence." It was so in the case of the Tulip bed. Supposing the new bed to have been made up at some time towards the end of the summer, or the old bed turned thoroughly throughout, it was allowed to have one good soaking of rain, and afterwards protected from wet till after the bulbs were planted, which was generally done during the first or second weeks in November. I have assisted at this ceremonial; it was done in the most painstaking and careful manner in the days when collections of named Show Tulips of good quality were valuable.

A Tulip bed is always raised and enclosed with boards, or, in the case of permanent beds, with turf sides. These may be set down as averaging 6 in. in height. One of the best of the southern growers of Tulips thirty years ago recommended cultivators at the time of planting to rake the surface of the bed level with the top of the boards which enclosed the soil, and plant the Tulips on the surface, covering the outside rows about 3 in. and the middle 5 in., which rounded the outer surface of the bed sufficiently to throw off an immense quantity of water in winter, and so do away with the necessity of covering from heavy rains until the plants were 2 in. or 3 in. out of the ground, and the foliage begins to hold water. This practise was considered to be as essential to good cultivation as thorough under-draining and the employment of good sound loam free from wireworm. The mould should never be allowed to sink below the side-boards, as then the whole of the water runs into the bed instead of on the path, which should have a trifling inclination for the bed. Cases of failure have occurred with Tulips, generally in the experience of unskilful amateurs, and in all probability these results were traceable to a superabundance of water retained in the beds by side-boards, or from continually covering them against heavy rains in winter, which draws the plants up weakly and renders them incapable of encountering severe frost.

November 9th was the traditional day of the generally accepted month for planting. Some growers planted in October, doing this before the bulbs began to vegetate at the base, and on the principle that the planter was not so likely to injure the young fibres in the act of pressing the bulbs into the soil. The usual rule is to put some silver sand about the bulbs at the time of planting, and some growers add a little powdered charcoal also. Skilled growers sometimes add chemical substances; but they require to be used with great caution, and not without full knowledge. It not unfrequently happens that the bulbs first planted are the last to make their appearance, although they are generally the strongest plants when they do come. When the bulbs are planted as directed, they do not require much attention until they are well out of the ground, when they should be covered with garden mats every night the last thing, and not allowed to have any rain, excepting the weather is very hot and dry, until blooming time; if canvas is used for covering, care should be taken to keep the sides up on warm nights, or during warm rains, to prevent the plants from being drawn up weakly.

When the plants begin to make their appearance above ground, the mats are removed on all favourable days, and also nights, when the weather is sufficiently mild to dispense with the precaution; but it is well to err on the safe side, in case of uncertainty at such seasons; for if the bud in its embryo state should be injured by frost or blight, all prospect of a good bloom is destroyed. When March sets in, it is advantageous to stir the surface soil of the beds, and this should not be allowed to become crusted on the top. The infant bud is in danger of being damaged at this season of the year if rain be allowed to gather in the centre in the midst of the leaves, and if this becomes frozen, a withered and imperfect bloom will in all probability result. If the weather proves very dry at the end of April, a

slight watering can be given in the evening through the fine rose of a watering pot, doing it over the foliage; and directly after this is done the bed should be covered with mats. When taken off the following morning, the plants will be found to have increased in freshness and vigour.

When the plants come into flower efforts will have to be made to so shade and screen the blossoms as to have them in as fine a character as possible. Shading is absolutely necessary, not only to protect the flowers from the sun, but side screens are most useful to prevent the wind from doing harm to any of the gems in the bed. Side screens should always be securely fastened, in order to prevent the material employed from being blown against and whipping the flowers.

If the question were put, Where are named Tulips now to be obtained? our reply would have to be from the growers at Manchester, Derby, Stockport, Ashton-under-Lyne, &c. Even Mr. Turner's once famed collection of named varieties has, it is feared, been broken up. The following list includes varieties that are shown at the Tulip exhibitions at Manchester, and it may be assumed that they are obtainable:—Bizarres (feathered)—Demosthenes, George Hayward, Sir Joseph Paxton, Ashmole's Garibaldi, Battersby's Herald, Commander, Slater's Masterpiece, and Birtwhistle's Sulphur. Bizarres (flamed)—Sir Joseph Paxton, Hardy's Ajax, Storer's Dr. Hardy, Storer's Orion, Storer's Masterpiece, Polyphemus, George Hayward, and Harley's Lord Delamere. Byblømens (feathered)—Headly's Adonis, Friar Tuck, Bessie, Mrs. Pickerell, Martin's 101, William Bentley, Mrs. Cooper, and David Jackson. Byblømens (flamed)—Hardy's Talisman, Duchess of Sutherland, Salvator Rosa, Hardy's Nimbus, Headly's Adonis, Bacchus, Lord Denman, and Constant. Roses (feathered)—Heroine, Kate Connor, Aglaia, Martin's Charmer, Martin's Mrs. Lomax, Annie, Industry, and Lea's Mrs. Lea. Roses (flamed)—Aglaia, Triomphe Royale, Slater's Kate Connor, Circe, Headly's Mrs. Headly, Martin's Annie Macgregor, Rose Celestial, and Mrs. Lomax.

It will be observed that the same variety is given as both feathered and flamed. It is the peculiarity of some varieties of the Tulip to come handsomely flamed on the sides and edges of the petals without the usual flame of colour running up the centre of the petal. But this, the definitions of the various sections, and other singular characteristics of this gorgeous flower need fuller explanation.

R. D.

HERBACEOUS PLANTS F. BEDDING PLANTS.

NEVER, perhaps, have these been seen in greater perfection than they have been during the present exceptionally wet summer and autumn, thus showing unmistakably how superior they are for general decorative purposes to ordinary bedding plants. The failure of these latter will do much to bring herbaceous plants to the fore again. Conspicuous just now are the *Anemone japonica* and its white variety *Honorine Joubert*, the latter a really charming plant, its flowers being as large as a crown piece, handsome in form, and very effective. Not only is this *Anemone* valuable in borders, but it is equally desirable for pot culture, and when placed in a cool greenhouse it is safe from winds, and lasts in bloom till a very late period. In order to grow either kind well, they require a deep rich soil and plenty of moisture while renewing their foliage, as otherwise they are subject to the attacks of red spider. The great point is starting them fairly at first, and then leaving them alone ever after, as old established clumps are always the strongest and best. Most kinds of herbaceous plants are greatly improved by being taken up now and then and divided, but not so these, as their nature is to form large roots low down, and it is from the young feeders on these they draw their supplies. In hot dry weather a mulching placed about them, and a soaking or two of liquid manure is of great assistance to them, as it enables them to push up their flower-spikes freely, and make fresh crowns around their base. Those who wish to begin with them in pots will find this a good time to lift any of the young side-shoots that spring up so freely from old plants. If these are dug out of the ground with care, and, after being potted, are kept close for a week or so in a cold moist frame, they will be found to have taken well hold of the soil, and in a condition to bear the air and exposure. Although perfectly hardy, when grown in pots it is always advisable to keep them plunged in a position secure from frost, as it should be borne in mind that a plant having its roots in such a small body of soil is very differently circumstanced to others in the open ground, where, deep-rooted as they there are, they cannot be injured. To obtain fine strong pot specimens requires some years of rich feeding, but so serviceable are they that they are worth more than the care and attention which their cultivation entails. *Rudbeckia Newmanii* is another flower that appears to bid defiance to wind and wet and holds its own against all conditions of weather. A clump here has been a mass of beauty for weeks past, and is so attractive as to arrest notice a long distance off, the blooms being of

a deep rich yellow, and the large disk perfectly black, thus affording a very striking contrast in colour. This *Rudbeckia* is not at all particular as to soil or situation, for it will grow almost anywhere, but flowers best in full sun, which, as it comes in rather late, is necessary to get it in perfect condition. Like most herbaceous subjects it admits of ready increase by division, which is best effected early in spring, as then it soon starts away and gets over the check. Another fine old plant that has been very conspicuous of late is the *Monarda didyma*, especially the scarlet variety, which is quite as bright and effective as the well-known *Salvia splendens*, which is held in so much esteem for the embellishment of greenhouses. Scarcely less noteworthy are the white and other forms of the same plant, which, when grown together, form handsome groups, the different shades helping to show each other off to the greatest advantage. Besides being well adapted for the back parts of borders, for which their height and size fit them, they are well suited for planting in semi-wild places where, when once established, their vigorous habit quite enables them to take care of themselves. To induce the *Monardas* to flower freely they should be planted where the soil is deep, loose, and open, and in exposed positions, so that they can have the full benefit of the sun, which not only makes them more free in blooming but preserves the heads from damping or being destroyed by wet that lodges in their close tufts of blossoms. One of the most persistent blooming herbaceous plants with which I am acquainted is *Phygellus capensis*, and yet good as it is one seldom meets with it in any garden. A grander subject, however, for the centre of a bed, to dot here and there as specimens on a lawn, or to grow in the back of a border, it is impossible to have, as not only is the foliage very attractive but it forms handsome bushes a yard high, each shoot being terminated with a large spike of flowers of a cinnamon colour, which, in form and general appearance partake of the character of those of the *Pentstemon*. Last winter, unfortunately, cut it about sadly, as it was slow in emerging from the ground, but like *Fuchsias* when in the open ground, the roots may be easily protected by having some non-conducting material thrown over the crown.

A plant which we have found exceedingly useful for cutting from is the *Genm coccineum flore-pleno*, which is a fine variety of the old-fashioned scarlet *Genm*, having much larger heads, the blooms being remarkably brilliant, and very enduring in water. Taking it altogether it is a very fine decorative subject, and one that should be in every border, where, if favoured with good soil, it will be found very free growing. Next perhaps in point of merit are the *Funkias*, the smaller growing kinds of which afford such a quantity of spikes of bloom that one may cut and come again, and, besides helping to fill the flower basket, they dress vases well, in which they are very showy and serviceable amongst others. In borders they are almost worth growing for the beauty of their foliage alone, so handsome and ornamental is it, its outline, rich marking, and noble aspect rendering it exceedingly attractive. For earlier blooming, the handsome *Spirea palmata* should not be forgotten, as unquestionably that is one of the very finest perennials in existence, sending up, as it does, large panicles of lovely violet-rose coloured blooms, which when in perfection are a real treat to look on. Although this lovely *Spirea* will grow almost anywhere, a shady moist situation suits it best, as there it soon attains great strength and size, and lasts much longer in beauty. One more very desirable plant I would just notice, the good old-fashioned *Dictamnus Fraxinella*, which not only yields up magnificent spikes of curious looking flowers, but is remarkably fragrant. There is also a white variety equally deserving of cultivation, and although they both used to be somewhat common in good collections they are now seldom met with. Better plants than the *Dictamnus* for shrubby borders cannot be, as, once planted, there is no fear of losing them, for so hardy and strong are they that they will take care of themselves.

S. D.

Mignonette Seed.—In common with many other hardy annuals, *Mignonette* has done badly during the past summer, and the seed crop will be but a small one. I have had great difficulty in getting plants from seed sown in the open ground, as, owing to the lateness of the spring and the coldness of the soil, the seed germinated badly; and of that which grew the young plants moved so slowly that they will produce but little seed in time to ripen. The best plants have resulted from those raised under glass, and planted out into the open ground when strong. In good seasons such plants of some of the large growing kinds will cover nearly three square feet, and bloom most abundantly up to the end of the autumn. Seed sown in September will yield good pot plants for the greenhouse in early spring; and seed sown in March, in small pots, make splendid plants to turn out for summer bedding. As next year seed will certainly be scarce and dear, it will be most wise to sow the seed as thus advised, none the less for the reason that it may have

poor germinating powers, as this is such a bad ripening season. As evidence of the probable scarcity of seed, I may mention that a large grower had such a failure of several acres that he was obliged to plough it up, and with what small quantity he has grown he hopes to make 5s. per lb. of the seed, instead of only 1s. per lb., the contract price with the firm for which he was growing the ploughed-up stock. In sowing seed next spring purchasers will have to be guided very much by its colour, because if white, or nearly so, it will never germinate; but if brown, it may be regarded as sound, if not too old. There are several kinds of recent selection, of which the best without doubt is Parson's Giant White, as white Mignonettes are much the best. Miles' Spiral is red, and produces long spikes; whilst the Diamond is a selection having very pointed spikes. Mignonette is with great difficulty kept true if other kinds are grown near it.—A. D.

SEDUM TRIFIDUM.

AN addition to the cultivated hardy Stonecrops is by no means a common occurrence, and more especially one which has flowers suffi-

Sedum trifidum (natural size); flowers rosy-pink.

ciently showy as to justify its being considered a garden plant. The annexed engraving represents a pretty species which is a common plant in the temperate parts of the Himalayas at an elevation from 6,000 to 12,000 ft. It is a dwarf-growing hardy perennial, with slender branches and crowded tufts of coarsely-toothed leaves. The flowers are of a deep rosy pink, very similar to those of the well-known *S. spurium*, or more correctly *S. stoloniferum*. Like the last-named species this Stonecrop makes a capital plant for growing on a rockery or a similar place, and continues for a long time in flower. Other low-growing kinds, well adapted for the purpose, are *S. oppositifolium*, with flowers of a pale pink; *S. Anacamperos*, with livid purple blossoms; *S. Ewersi*, with dense clusters of pink flowers; and *S. pulchellum*, a beautiful American species with forking clusters of rosy-lilac flowers. Our woodcut was prepared from plants in the Royal Horticultural Society's garden at Chiswick, which were presented by Mr. Elwes, who received the seeds from Northern India. W. G.

Pyrethrum Golden Feather.—There is in cultivation a double white-flowered variety of this which is quite an acquisition; it is one of the best plants with which I am acquainted for forming lines in ribbon borders, massing, &c.; it keeps long in bloom, and is

remarkably free in that respect. It is quite as easily raised from seed as the type, and if sown at the end of February or beginning of March in just a little heat, sufficient time will be given to get up good plants by the end of May; and the less coddling practised the better. I would recommend any one who has not tried it, and particularly those who have a goodly number of plants to raise in spring from seed, to give this a trial, and I think they will not be disappointed.—S. K., *Castle Upton*.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Wintering Half-hardy Plants.—Where the extent of glass for protecting plants during winter is limited, a good deal may be done by planting a portion of the stock on dry banks, or in any position where the amount of moisture during winter is reduced to a minimum. Many of the succulent plants, such as *Echeverias*, will stand a considerable degree of cold if dry, but succumb to slight frosts if wet at the root.—J. Groom, *Linton*.

Notes on Bedding Plants.—As regards plants just rooted, all should be at once got under cover, as the least touch of frost makes them difficult to winter; but, although housed, it will be necessary to afford plenty of air, and keep them as hardy as possible, as on this depends to a great extent their immunity from damp, for the harder the stems and leaves are the less liable are they to fog off when the days become shorter and dull. An old plant or two of *Lobelia*, *Heliotrope*, *Verbena*, *Ageratum*, *Mesembryanthemum cordifolium*, and such like, lifted and potted up now will afford plenty of cuttings in spring, which are always much better than autumn-propagated stock, and do not give a tithe of the trouble. Before getting any of these last named or other bedding material into their winter quarters, the walls of the pits, frames, or houses intended to receive them should be lime-washed and the glass cleansed, as it ought to be borne in mind that light is life to vegetation, and in the season now coming plants seldom get enough of it.—S. D.

Pyramid Pelargoniums at Clumber.—These reach 8 ft. and 9 ft. high, and still maintain a certain amount of gaiety in the terrace garden between the lake and the house, where they serve to relieve the somewhat sombre appearance of the clipped Conifers of the same form, with which they are associated. They consist of Beaton's Pink Nosegay, and are wintered under glass in a Vinery or other roomy house. It may be added that the ornamental grounds at Clumber, which had become sadly over-wooded, are being opened up and improved by Mr. Miller, who is now gardener there.—M.

Impatiens glandulifera.—Amongst other seeds kindly sent to us by Mr. Entwistle, of the Manchester Botanic Gardens, was this Balsam. It has grown vigorously, and is now an immense mass over 6 ft. in height and 4 ft. through, covered with pink flowers not unlike the poke bonnets at present in fashion, and each flower, being about 1½ in. in length, gives the plant a quaint and pretty appearance. But its most interesting peculiarity is the seed vessels, which resemble Radish pods, and burst with a loud crack on being touched, scattering brown, pillet-like seeds in all directions, and frequently in the face of the beholder. My little folks quite enjoy this plant, and take all visitors to it, in order to witness their surprise at being shot. Its habit is exactly like that of our greenhouse Balsam, only that it grows vigorously in the open garden. Our English Balsam, *Noli-me-tangere* or *Touch-me-not*, has the same peculiarity of discharging its seeds on being touched, but in other respects it differs greatly from the *Impatiens glandulifera*, having only four or five yellow flowers resembling those of the *Mimulus* of our gardens.—BROCKHURST.

Double Rockets.—I am much obliged to Mr. Williams, of Ormskirk, for his notes on the old double White Rocket (p. 325), which I was under the impression still existed about the neighbourhood of that town; but Mr. Williams says that it is not found there now, having disappeared as it has done from other places. Certainly about fifty years ago it was plentiful enough in the north of England, and it was not until about 1841 that I became acquainted with the giant or French one, which, when well grown, is really more useful than the old dwarf. I do not think, however, that the latter is lost sight of yet; about 1865 I met with it in an old garden a few miles from Glasgow, and brought a plant of it into Kent. Since then I gave it to several people as it seemed to thrive pretty well, though it was not robust. I have lost the purple several times during my life, but I fear more than once through inattention. It seemed to be taller in habit than the old dwarf white, though not so tall as the large one. I think there were two purples at one time; one simply a mauve colour, the other much darker. Mr. Williams is right about the yellow one not being a Rocket at all, but it is, nevertheless, a very pretty and desirable plant. The old double

Scarlet *Lychnis* is inferior to the old double Catchfly, a plant much neglected now-a-days, but it well deserves to be restored to the position which it once occupied.—AN OLD GARDENER.

Sedum spectabile.—This is a real gem amongst hardy plants, and one which must again come to the front, for it is so easily grown and flowers with such profusion under any kind of treatment, that once grown it is sure to recommend itself for further cultivation. In altering some large beds here last winter, some old-established edgings that had evidently stood many years in one place were lifted and planted wherever edging plants were required, and they have flowered magnificently, and for the last month have been borne down by their load of rosy-pink blossoms. Some planted on raised root-work in the full sunshine, where scarcely anything else would have grown, have been exceedingly bright and cheerful; while others planted in shady situations have been paler in hue. A quantity that were laid in the reserve garden, too, made such pretty decorative plants that they have been lifted and transferred to better quarters. This *Sedum* is extremely useful as a pot plant, and though left for weeks without water it does not suffer; in fact, it is proof against insects, or disease, or neglect, but it nevertheless well repays generous treatment. In looking over the cemetery gardens at Maidstone the other day, I observed this plant used as a centre for round beds of succulents, edged with double rows of *Echeverias* or *Sempervivums* of the hardy kinds, and they certainly were well worth imitating, being neat and trim at all seasons, and promised when the large, flat heads of *Sedum spectabile* were fully expanded to be a sight worth looking at. A sunny position should be chosen for this *Sedum*, but, as before stated, it requires no "special compounds" to grow it to perfection.—J. GROOM, *Linton*.

Border Polyanthuses.—The month of October presents by far the most favourable time for the lifting and division of old bottoms of these plants; and it is a work that should be done every two years at least, as the plants are by the very conditions of their growth forced year after year higher and higher out of the soil, and as the crowns increase there is less root room to be found for all. I find, in a couple of years or so, that strong-growing kinds will give a close cluster of some twelve to twenty separate crowns, each one rooted, yet each one united to a common base. If now these stools are lifted and pulled to pieces, each crown being severed from the base just below its new roots, and these are planted separately, they will make strong single plants next spring, and very robust plants the succeeding year. In some cases assistance can be given to old plants, that it is not desired to lift, by giving a liberal top-dressing of old pot soil about the surface roots, but this should be but a temporary expedient. Just now all the varied kinds of border Polyanthuses are throwing up numerous flowers; in fact, it is with them quite a spring time. Here hundreds of all kinds and colours are in bloom, and though not so fresh and welcome as in spring, they are exceedingly beautiful. Primroses are in the same way, and are now expending the store of autumn crown-bloom that is usually reserved until the spring. Yet how charming are these plants now when compared with the tender bedding plants so widely grown with so much trouble, and this year with so little satisfaction. Some that show promise of a good head of bloom may well be lifted into pots to help to make the greenhouse look gay for a season. The present blooming is also advantageous for those who wish to use these hardy plants for spring bedding, as it enables the colours to be correctly arranged.—A. D.

Flower Garden Notes.—Amid the wreck of autumn, there are still a few plants so superlatively good, after passing creditably through the past extraordinary summer, as to attract special notice. The varieties of *Phlox Drummondii* are still (October 11) in beautiful condition. The heavy rains do not seem to have injured them in the least, proving that they are eminently suited for a rainy district; and, judging from the present appearance of the beds and the successional flower heads constantly rising up, if the frost keeps off, they will go on flowering for weeks yet. It has been stated in a contemporary that this year the *Phloxes* have done best where sown in the open air in the position they are intended to occupy, thinning out the plants to about 6 in. apart; but this season has been so much out of joint, no one should have a theory upon its effect in the case of any class of plants. But there is no doubt that many kinds of annuals raised in heat in spring are impaired by too much crowding in small pots or boxes under glass before the period arrives for planting out. I have been so long convinced of this, that I never sow such things till April, and, after giving a start in gentle heat, prick them off and move them on to cold frames immediately. In this way the young plants are kept dwarf and sturdy, and the beds can always be of the same thickness all over, which is not always the case when sown where they have to flower, as little plants early in the season have a good many enemies to contend with. Another class of plants that have been remarkable for brilliancy of colouring

this wet season are the Marigolds, and they have never been brighter than at the present time. But the most remarkable yellow mass we have had this year is the old *Calliopsis Drummondii*. There has never been a break in its flowering, and it is still as full as ever. Sub-tropical plants have not attained to the same size as in former years, but the growth of variegated Maples, *Ailantus glandulosa*, and *Tamarix* has been remarkable. And the same may be said of trees and shrubs generally, especially young specimens. Among hardy plants that are now wonderfully attractive, are several species of *Rudbeckia*, with large yellow salver-shaped flowers; patches 1 ft. or more in diameter, in good soil, have a very striking effect, as have also strong patches of *Sedum spectabile*. One large bushy specimen that has been some time in flower fills a stone vase, where it stood out through the severe weather last winter, so no doubt need be entertained about its ability to stand rough usage and any degree of cold. Among *Michaelmas Daisies*, *Aster Novæ-Angliæ* is now very showy, having large blue flowers with dark disk. The Pampas Grasses, of which we have several groups, are fast showing their white plumes, which although as numerous as formerly, are hardly so tall and fine. Tuberous *Begonias* are still full of flowers in the beds in the garden; the two or three nights of slight frost do not appear to have injured them. There is a marked contrast between the *Begonia* beds and the *Pelargoniums*, much in favour of the former.—E. H.

Orchises on Great Ormes-Head.—I think the botanist who found (p. 346) *Orchis hircina*, *O. arachnites*, and *O. fusca* wild on the Ormes-Head was dreaming when he did so. The whole of the Llandudno Mountain has been worked to death by botanists, and none of the three have ever been recorded on good authority; anonymous statements will hardly be considered sufficient to prove such improbable discoveries. The local Orchises found abundantly on the mountain are *O. pyramidalis* and *O. conopsea*. I believe *O. apifera* has been found, but I searched the whole mountain carefully this year without finding it. *Orchis maculata*, with all its varieties of colour, is very abundant, and some of its forms might be rather like *O. fusca*; *Spiranthes autumnalis* also abounds there. *Listera cordata* is, I believe, found, but the rarest *Orchis* I found myself in some plenty there is *Epipactis atro-rubens*. It is curious to find any one signing himself "Botanist" mentioning *Asperula odorata* and *Lysimachia Numularia* amongst rare local plants.—C. W. D.

— "A. R." North Wales, whose attention has been called to the discovery of the *Orchis hircina* on the Ormes-Head, as recorded by "Botanist," has, I believe, very just cause for his doubts. Some time ago I had a communication from a person at Llandudno, directing my attention to a notice in a contemporary of a visit to the Ormes-Head in search of plants. The report appeared on October 4, describing, among other things, the finding of *Thalictrum adiantifolium*. No such plant exists in the British flora, and the name, I believe, is only a trade term for some species of *Thalictrum*. I know the Ormes-Head and its botany well, and have had the honour of going twice from Liverpool there with the botanical section of the Field Naturalists' Club. I have the said *Thalictrum* brought from there growing in my garden. I believe that among botanists it is referred to *T. minus*, or a form of it. It is well known that the Ormes-Head is famous for being the habitat of *Cotoneaster vulgaris*, but I never heard of its growing in the spot indicated, viz., near the "lighthouse;" I only could find it on the east side of the mountain, just above the town. I am afraid that this very same plant will soon, as a British plant, become extinct.—THOS. WILLIAMS, *Ormskirk*.

Two New Ornamental Grasses.—The *Holcus lanatus aureus* is a charming Grass, unlike any other with which I am acquainted. I found it on the wayside near Chilwell last spring. Its leaves, tinted with gold, are very handsome. The other, *Alopecurus pratensis argenteus*, is also distinct, the flower-stems being ivory white, and the foliage beautifully striped with green and white. This is also a roadside Grass, and one which I found last winter on the Burton Road, near Derby.—W. ELLIOTT, *Stockbridge, near Sheffield*.

Francoa ramosa.—This fine old Chilean plant is grown extensively by Mr. Jones, at Frogmore, for general decorative purposes. It is admirably adapted for cutting, as its long, branching stems, bearing numerous white blossoms, have a capital effect when mixed with other less elegant flowers. The plants are raised from seeds, and treated subsequently much in the same manner as the ordinary herbaceous *Calceolarias* are. In spring they furnish a large supply of flowers for a long time. No doubt the other kinds, *F. sonchifolia* and *F. appendiculata*, would be equally desirable, especially the former, as its flowers are scarlet, marked with a deeper spot in the middle of each petal. In *F. appendiculata* the flowers are of a paler hue, but it is a very beautiful plant. All these should be more generally grown than they are, besides a host of other well-tried plants.—W. G.

NOTES OF THE WEEK.

A New Water Plant (*Herpestis reflexa*).—It is an interesting fact in connection with a large number of aquatic plants that their foliage is cut or divided into numerous fine segments. Some noticeable examples of this in our native plants are the Water Violet (*Hottonia palustris*), and the Spiked Myriophyll (*Myriophyllum spicatum*), the Water Crowfoots (*Ranunculi*), and others. There are none, however, that excel in beauty and delicately-cut foliage this pretty exotic, which may be seen in the Water Lily House at Kew. The plant is wholly submerged except a few inches of each shoot, which is furnished with whorls of finely-cut pectinate or comb-like foliage, very similar to that of a *Neptunia* or the plants just named. The pleasing emerald-green of the leaves considerably enhances the beauty of the plant, and more particularly so at the time we saw it, when the delicate azure-blue flowers of *Nymphaea stellata* were springing up amongst its elegant feathery foliage. It belongs to the Figwort family, and is a native of Brazil.

Gentiana Kurroo.—In Mr. Bull's nursery this very beautiful hardy perennial from Northern India is now finely in flower. It is of dwarf habit, with the rather long, linear leaves arranged in compact tufts. The flower-stems are slender, terminated by a tubular blossom about 2 in. long. The colour is greenish-white on the outside of the tube; the broad divisions of the corolla are bright, clear blue, copiously speckled with white dots, except at the edges. It is apparently a vigorous grower, as it is thriving and flowering well in the open air. Such a distinct and beautiful plant will certainly find favour with all lovers of hardy flowers, and we are pleased to see that it has been successfully imported in considerable quantities.

Odontoglossum Londesboroughianum.—Though there are so many Orchids with yellow flowers, such beautiful kinds as this will always be appreciated. The high encomiums that have been passed upon it are by no means unmerited, a fact which a sight of the specimens now in flower in Messrs. Veitch's nursery fully confirms. The flowers, which form a loose cluster terminating an erect stem, are about 1½ in. across, the lip being broad, of firm texture, and of a clear rich yellow, forming a pleasing contrast to the other segments, which are distinctly barred with deep greenish-brown on a dark olive-green ground. It is gratifying to know that this handsome species has been imported in considerable quantity, so that it will probably become generally distributed in collections.

Hoya australis.—This species of *Hoya* is but seldom seen, though it is quite as old an introduction as some of the others, and quite as beautiful. Its habit of growth is very similar to that of *H. carnosa*; it has the same trailing habit and leathery, oval leaves, from the axils of which are produced clusters of star-shaped blossoms. These are somewhat larger than those of *H. carnosa*, thinner in texture, and the petals expand fully. The colour is white, inclined to pink, with a deep carmine centre. The long time during which the flowers last in perfection, together with its free-flowering tendency, make it a plant well worth attention. Like its congener, *H. carnosa*, it is a native of Australia. It may be seen in flower in the Water Lily house at Kew.

Ipsa speciosa.—This is a beautiful terrestrial Orchid though but seldom met with. It is of *Bletia*-like habit, with conical bulbs and lance-shaped plaited leaves about 1 ft. long. The flowers, which are borne singly on erect slender stalks, and about 2½ in. across, are of a bright yellow hue with the lip delicately pencilled with chocolate. It is a native of Ceylon, and was introduced to cultivation about forty years ago. We saw examples of it in flower a day or two ago in Mr. Bull's nursery.

Begonia Martiana.—This fine old plant is still unsurpassed by not a few of the new comers, especially when seen as grown by Mr. Barron at Chiswick. The plants are in pots, and the rather slender shoots, which are supported by sticks, are covered from almost the base to the extreme tip with large rosy-pink flowers, which have a central tuft of golden stamens. The flowers possess a peculiarly pleasing shade of colour, which is apparently unobtainable in the ordinary tuberous-rooted group. The numerous gemmules or incipient buds that are produced at the leaf axils, and also at points from which the flowers have fallen, is an interesting point in connexion with this species, as by this means the plant may be propagated extensively. Some plants of this kind were shown from Chiswick at the last meeting at South Kensington, and were much admired.

Bomarea oligantha.—This handsome climbing Amaryllid is finely in flower in the Pine-apple Nursery, Maida Vale. Its elegant habit and numerous drooping umbel-like clusters of flowers, which are of an orange-red colour and singularly spotted, render it very desirable for training to a pillar or rafter in a cool greenhouse, and it is all the more valuable on account of the succession of

bloom which it produces for several months in the year. Its congeners, *B. Carderi* and *B. Caldasi* are even more beautiful, as in the former the flowers are considerably larger, and both are brighter in colour than *B. oligantha*. They thrive well under pot culture, but are more satisfactory when planted out so as to allow of plenty of root development.

Tillandsia musaica.—This is a very handsome Bromeliad even when out of flower, the peculiar markings of the foliage being so distinct. It is not of the type usually seen in this class of plants, but it has hieroglyphic-like streaks of a dark tint running across it transversely, which have a singular appearance on the olive-green ground colour. A fine specimen of this plant in Mr. Bull's nursery is now bearing several spikes of blossoms, which are arranged in crowded clusters produced from the centre of the tufts of foliage, and consist of a series of orange-scarlet bracts, enclosing white-tipped yellow flowers. It is altogether a very handsome plant, and one that should always find a place in choice collections of decorative plants.

Boussingaultia baselloides.—This pretty South American twining plant is a conspicuous ornament in the Palm house at Kew, where it is now in full beauty. Its long festoons of small white blossoms, borne in graceful profusion, have a remarkably fine effect when seen suspended from either the roof or a pillar. It is quite hardy, but is by no means a satisfactory plant to grow in the open air in this climate, as it seldom attains more than a few feet in height and never flowers. For a stove or warm greenhouse, however, there are few more elegant plants, and its culture is of the simplest kind.

Pear Trees at Frogmore.—A somewhat novel mode of training young Pear trees is practised by Mr. Jones in the Royal Gardens at Frogmore. It is a modification of the cordon system. In every available unoccupied space against the walls rendered vacant by the removal of old trees, or where the extremities of the branches trained in the ordinary way have not met, maiden trees are planted, and their lateral or side shoots are trained so that the tips point downwards. The abundant crops of excellent fruits which every tree bears are evident proofs that this system, combined with other conditions, is highly conducive to productiveness, and it is a plan that is worth attention, especially in places where wall space is limited, as by this means a wall may be covered, and annual crops taken from the trees in a considerably less time than it requires to train trees in the ordinary way.

Yucca falcata.—A handsome plant under this name is now finely in flower in Mr. Peacock's garden at Sudbury House, Hammersmith. It is in the way of *Y. recurvifolia*, but is much more compact in growth and has much narrower leaves which have not a recurving tendency. Its large panicles of ivory-white blossoms, together with the noble habit of the plant render it a very desirable subject for conservatory decoration, and treated in that way it preserves its beauty for a much longer period than if fully exposed. It is, however, considered by Mr. Croucher to be quite as hardy as the better known kinds.

Bouvardias at Wortley.—During a recent visit to Wortley Hall I saw some well-grown *Bouvardias*. They consisted of elegans and *Vrelandi*, in the form of dwarf, compact bushes, the heads of some of which must have measured fully 2 ft. through, and they were one mass of flower. The largest plants were in 7-in. and 8-in. pots. They had been housed a few days previous to my visit, but had been plunged in the open ground fully exposed since the early part of June. Mr. Simpson assured me that they had not had a sash over them since that time, thus fully dispelling the old theory that *Bouvardias* must be grown under glass to do them justice.—G. SUMMERS, *Sandbeck Park, Rotherham*.

Ampelopsis Veitchi at Frogmore.—One of the sights now to be seen at Frogmore—and a beautiful one it is—is *Veitch's Ampelopsis*, splendid masses of which cover the walls and pillars at the entrance to the garden. A more gorgeous sight than is afforded by this Japanese climber could not well be imagined. In an exposed position, as in this instance, the plant assumes its full character in autumn, but in places where it is shady the leaves remain green until they drop; instances of this may be seen in some of the original plants that are planted against the walls in Messrs. Veitch's nursery at Chelsea. At the entrance to the Frogmore gardens, the walls form a semi-circle with prominent buttresses at intervals. Against these are planted the *Ampelopsis*, and between each a deep green foliaged tree, and the contrast thus afforded is remarkably striking. Amongst the plants there is an unusually deep crimson-leaved form, the foliage of which moreover is somewhat larger than that of the type; and this difference is not in any way owing to aspect, as the ordinary forms are planted by its side on the same exposure. The brilliant hues of the fading leaves alone render this

climber a most desirable subject, but its value is much enhanced by its peculiar habit of clinging to walls without the assistance of nailing, a feature of no small importance under some circumstances. This plant is also known as *A. tricuspidata*. In the same garden is planted largely the Fire Thorn (*Cratægus pyracantha*) a well-known, brilliant, berry-bearing autumn shrub.

New Winter Garden in Belgium.—The King of the Belgians has just had constructed a spacious winter garden in his park at Laeken. It is the largest on the Continent. The cupola, made of iron and glass, is 60 metres in diameter and 30 metres in height. It is supported by thirty-six columns of white marble, each being one metre in diameter.

Seed Failures.—The following vegetable seeds are stated by the Seed Trade Association to be almost total failures, viz., Wrinkled Peas, Cauliflower, Altringham and other varieties of Carrot, Ridge Cucumber, Musselburgh Leek, Paris White Cos and other sorts of Lettuce, English varieties of Onion, Mangold Wurzel, and Scotch Turnips.

The French Vineyards.—Mr. R. Cuddeford, of 66, Mark Lane, sends *The Times* the following copy of a letter just received from Mr. Ernest Irroy, one of the large Vineyard proprietors in the district of the Marne, France: "Here in Bouzy and Verzany, &c., there is not a Grape ripe, a circumstance amounting to quite a disaster, the worse because the wood of the Vines is also immature, and the next vintage for the year 1880 will not be a good one. As the leaves of the Vines are fallen, I am now cutting the Grapes that are red; there is about one-fourth red, the remainder are green. I shall leave the green ones in the Vineyards. Nobody remembers to have seen such a state of things in Champagne."

The Mitcham Flower Farms.—Dr. Septimus Piesse, of Hughenden House, Chiswick, writes, in reference to his Lavender and Peppermint farms at Mitcham, and to those of other growers in Surrey, including Merton and Carshalton, and Hitchin in Hertfordshire, that the produce this year has decreased 40 per cent. below a seven-years' average, and 55 per cent below that mentioned in *The Times* of August 22, 1876, from which date the crops have suffered from want of sunlight and temperature.

Chrysanthemum Societies.—The following will hold their annual exhibitions on the dates annexed:—Birmingham, November 26—27; Hackney, at the Royal Aquarium, Westminster, November 19—20; Brixton, November 13—14; Southampton, November 18—19.

Floral Decorations at Sheffield.—Amongst other things connected with the visit of H.R.H. Prince Leopold to Sheffield to open the new Firth College, the floral decorations at the Victoria Station by Messrs. Fisher, Son, and Sibray, of the Handsworth Nurseries, deserve commendation. The semi-circular reception platform was capitally arranged. Amongst a wreath of *Dracænas*, *Crotons*, *Palmus*, *Adiantums*, and other Ferns, were grand spikes of *Gladioli*, *Phloxes*, *Liliums*, &c., exemplifying as THE GARDEN has so often urged the great value of these autumnal flowers as decorative subjects at a time of the year when brilliantly coloured flowers are the exception. Two memorial Oaks were planted by the Prince in the grounds of Oakbrook, the residence of Mr. Mark Firth.

Vines not Ripening in France.—It is not only in England the past season has been bad. M. Guichenot tells us that the Grapes have not ripened in Anjou, but are yet green and hard. It is, of course, the same in many parts further north. Pears are of very inferior quality about Angers, which is generally a capital region for fruit.

The Woolly Aphis.—I strongly advise "Delta" to stick to the paraffin cure for this pest of the *Auricula*, but he should use it a little more liberally, and not in homœopathic doses. My proportion is four or five tablespoonfuls to a gallon of water; stir it well first, then in application turn the plant out of the pot, dip the ball right into the mixture, giving it a turn round in it to ensure its equal distribution, then drop the plant at once into a clean pot of the same size as the preceding one. I have found this to kill all aphides, and not to injure the roots in the least. A plant of *Primula denticulata*, growing in a 5-in. pot, and which had been standing amidst some affected *Auriculas*, had a perfect mat of the most minute rootlets and many large feeders. This ball was literally smothered with the aphis; in fact, was as white as snow. This I dipped, as stated, and killed all the enemy; but, wishing to see how far paraffin might affect the roots, I dipped it again twice at intervals, and although for more than a week after the ball smelt most strongly of paraffin, yet not a rootlet appeared to be the worse. I think this is a matter of the first importance, and especially to *Auricula* growers. It is noteworthy that, as far as my own observation goes, this aphis does not attack *Auriculas* or allied plants in the open ground.—A. D.

PLATE CCIII.

A GROUP OF PYRETHRUMS.

Drawn by CONSTANCE PIERREPONT.

THE perfection to which the varieties of the *Pyrethrum* have been brought places them amongst the most useful of hardy flowers. Their elegant Fern-like foliage, diversity of colour of their flowers, their continuous habit of blooming, combined with the simplicity of their culture, render them almost indispensable to every garden. Their perfect hardiness, too, is another point in their favour. They grow in almost any position and soil, but thrive best in an open border in a rich and rather stiff soil, though some of my plants have grown admirably in a light soil in a shady border. Under such treatment they attain a height of 8 in. in the dwarf-growing kinds, and nearly 3 ft. in the more robust sorts. They are capital plants for cutting from, as they last such a long time when placed in water; and for this purpose they are specially valuable, as they begin to flower in spring when there are but comparatively few other plants in flower, and last throughout the summer till late in autumn. In order to obtain fine blooms late in the season, the withered flowers of the early crops should be continually removed, and the plants should be mulched with manure so as to encourage a vigorous growth. They may be freely propagated by division or offshoots. They may be increased also by seeds, which, in some seasons, are produced plentifully, and it is very interesting to watch for new colours and forms. As may be seen by the accompanying plate there is a wide range of colour, varying from pure white and golden-yellow, through pink and red to the deepest crimson, and almost every conceivable intermediate shade of tint. Like many other kinds of *Composites* which have been manipulated by the florists, there are several types of arrangement of the florets; for instance, in the original kind, as in *roseum nanum* on the plate, the central florets are yellow and the others of a deep rose. These may be termed the single-flowered kinds. In the fine variety, *J. N. Twerdy*, at the top of the plate, the florets are all strap-shaped, making a *Chrysanthemum*-like bloom. The white kind, *The Bride*, the yellow *Nancy*, and *Progress*, are examples of the quilled-flowered section, which are similar to those of the quilled-flowered *China Asters*. The intermediate form between the *Chrysanthemum* and the quilled-flowered groups may be seen in *Paul Journet*, and also in the lowermost bloom on the plate, which has the centre of the quilled form, and the outer of strap-shaped, either of the same colour or different shades of one colour. There is now a long list of named varieties to be found in trade catalogues, and, though they are for the most part distinct, there are many in which the colour of the flowers nearly approach each other. The selection of blooms figured was from a collection of ninety varieties. If a good selection is once grown there are not many who would care to be without them, and they certainly ought to be more generally grown in every garden.

Byfleet.

[The specimens from which our plate was prepared were supplied by our correspondent from his garden at Byfleet.]

Alpine Plants and Rockeries.—Mr. Goldring's description (p. 344) of Messrs. Backhouse's rockwork will cause many to be "in a strait betwixt two opinions." It will either induce people to attempt to build rockwork in some form or other, or it may deter many from attempting the construction of rockwork or growing Alpines at all. The ridicule associated with puny rockwork on the one hand, and the noble rockery at York on the other, are calculated to make people for ever abandon the attempt. As a lesson, the rockery at York teaches too much, being a lesson that few can learn; and, perhaps, conveying the erroneous idea that such rockwork as that at York is necessary in order to grow Alpine plants to perfection. The broad fact is, there is too much fuss made about Alpines, which may be, and are, grown well without any rockery at all. People should look at the noble rockery at York not as a necessary adjunct to the tradesman in Alpines, but as the outcome of a refined and liberal taste, such as very few private persons, and fewer tradesmen, have in their power to imitate. The rockwork at York is certainly a triumph of imitative art, of which I am sorry to say few examples exist. Most of the parks, gardens, and public squares in England are disfigured by abortions called rockeries. With me it is a fixed rule to judge of a person's taste by his rockwork. A very pleasing little book could be written on "Reminiscences of Rockeries," and though the desire to possess rockwork of some kind is almost universal, from the rockery of Mr. Tomkin's, with stone lions, carved men's heads, and pieces of fluted columns, to the cliff at Chatsworth, yet in most cases rockwork is little better than a parody on Nature. Though these remarks may be digressive, I cannot conclude without adverting to the very

comprehensive meaning attached by some people to what are called Alpines. One is led to imagine that instead of their being tender, delicate, costly, and difficult to grow, they must be on a level with Groundsel and Chickweed, seeing they are offered at something less than 2d. each in THE GARDEN of last week (the 18th). One hundred Alpines for 18s. ! barely the price of three first-class Alpines.—THOMAS WILLIAMS, *Ormskirk*.

THE FRUIT GARDEN.

PLUM TREES IN POTS.

KNOWING how manageable Plums are in pots, one is led to ask why more attention is not given to that system of culture. A comparatively small house will shelter a great many trees in spring during the flowering period; and after the fruit is safely set, and all danger from spring frosts passed away, half or more of the trees might be plunged in the open air, with the certainty of their doing well. Except in favoured spots, where the climate is good, Peaches or Apricots would not ripen well under this treatment; but Plums may be safely relied on everywhere to do so. Most kinds of Plums readily assume the pyramidal form, and this shape is the most suitable and profitable, as more fruit can be obtained from a given space by this mode of training than any other. The autumn is the best time to lift and pot the trees. They should be lifted with all the fibrous roots possible. The long roots should be shortened back, for the double purpose of encouraging the production of fibres and rendering the employment of convenient-sized pots possible. Plums under pot culture are long-lived, and it is advisable to confine them within the limits of as small pots as is consistent with health and vigour. Fruit-growing in pots is mainly a question of rich mulchings and liquid manure; therefore very large pots will not be required for several years. Gradually, of course, as the trees increase in size, the root space must be augmented, until they occupy 15-in. pots, in which size they will continue in good bearing condition many years, if well fed.

The soil they are potted in should be good sound, fibry, somewhat adhesive loam. All stone fruits are benefited by having a proportion of lime in the soil; therefore, if the soil in the neighbourhood is of a non-calcareous character, a little chalk might be added when chopping up and preparing the soil for potting. As the trees in the growing season will require a good deal of water, the drainage should be carefully laid in the bottom of the pots, but not more than is necessary to effect this object should be used—one crock over the hole so arranged as to keep out worms, and at the same time allow the water to pass through freely; over this a layer of rather large crocks 2 in. thick, and over the top of the crocks a layer of new Cocoa-fibre. This latter substance is excellent for keeping the drainage clear, and should be used for the purpose more than it is done, as its tough fibrous nature makes it so lasting. I have alluded to this matter somewhat fully, as drainage must form the basis of all good cultivation, both in pots and elsewhere. I have already stated that loam should form the main bulk of the soil for all fruits, adding more or less of manurial matters as may be necessary to supply anything that is lacking in the natural soil. Thus, chalk to supply lime; bones, again, to a certain extent, supply lime in addition to other valuable constituents when used fresh, though in this case the lime is not immediately available. Horse-droppings, shaken from the straw and laid up with the soil for a time, will supply most of the manurial elements that fruit trees require, with little cost of money or time, though cow or pig manure will be better for light hot soils, as they are of a cooler nature. But when I have, from necessity, had to use such soils for fruit culture, I have always contrived to find some clay to mix with it. The clay should be laid up till it becomes perfectly dry, then break it up on a hard floor into powder, when it will thoroughly mix with the soil, in a condition for the roots to work among at once. Firm potting is essential, and rich mulchings of old turf and manure are very beneficial when the crop of fruit is swelling. The plants will not require potting every year; indeed, after they have reached 15-in. pots they will continue fruitful for a number of years with annual top-dressings, removing as much of the old surface soil as can be taken out without doing much injury to the roots, and filling up with good turf and manure, ramming it well down.

The summer management of Plums in pots is a very simple matter, much more so than with Peaches. It consists in keeping the young wood thinned out to let in air and sunshine, and pinching the young shoots back to four good leaves, and using the syringe or garden engine often during fine bright weather. Whatever top-dressing or pruning is required should be done in autumn, as soon

as the leaves fall, and the trees then be grouped together either on a coal-ash bed, a paved floor, or on boards in the open air; and the pots should be surrounded with litter, to keep the frost from breaking them and to protect the roots of the trees. In this position they will remain till the buds begin to move, when they should be taken indoors. It will be an advantage, also, if there is a flow and return hot-water pipe in the house, although this may not in all cases be necessary, as the nights in spring in which fire-heat will be wanted, even in unfavourable districts, are few in number, and some temporary expedient, when the trouble was not rated high, could be adopted. For instance, many a crop of fruit might be saved in an unheated orchard house if a couple of ordinary paraffin lamps or candles could be lighted and kept burning all night for the very few nights that frost prevails. A pot or two of hot ashes would also give off a good deal of heat for some time. Sometimes the trees under glass set more fruit than they ought to carry; and in that case thinning, of course, should be resorted to in good time. The following list of Plums are well adapted for pot culture: Early Transparent Gage, Golden Drop, Green Gage, Huling's Suprb, Jefferson, Kirke's, Reine Claude de Bavay, Transparent Gage, Washington, Angelina Burdett, Early Favourite (Rivers's), Victoria, Cox's Emperor, Belle de Septembre, Autumn Compôte, Goliath, Pond's Seedling, and Prince of Wales. It will be well to have several trees of such useful free-bearing kinds as Transparent Gage and Golden Drop in preference to a large number of varieties. The kitchen varieties would be mostly turned out in the open air as the weather became suitable, and only the best dessert kinds retained in the house to ripen.—*Field*.

SWELLING AND RIPENING OF PEARS.

It would be interesting to know how the different kinds of Pears have behaved in the various localities this very exceptional season. Some kinds, so far as regards size and appearance, seem almost equal to ordinary years, but others are absolutely worthless. So far as I have had opportunities of observing it is, as might be expected, the late keeping sorts that are deficient in size; they are starved, stunted, and cracked, and often disfigured by mildew. It may be a mere fancy, but I cannot help thinking that those kinds with a brown or russet skin, such as the Winter Nelis, are much in advance, *i.e.*, they seem to be less affected by the unfavourable character of the season than those with a green or lemon-coloured skin, of which Glou Morceau may be taken as the type, and which is this year absolutely worthless, although it is, in ordinary seasons, one of our best Pears for winter. Marie Louise and Beurré de Capiamont are little, if anything, below their average size, and though the latter is not a first-class Pear, yet it is so sure a bearer, and the tree is under all circumstances and in all soils such a good grower, that it is worth planting by those who plant for profit. Pears are very likely to ripen unequally this winter, and some of the winter kinds will be much improved by being placed in a warm cupboard, or in some position where the temperature can be raised to 55° or 60°. Very often such late Pears as Ne Plus Meuris and Beurré Rance will not ripen or become melting at all without this help from a little artificial heat during the last month or so. Some kinds of Pears, if left on the trees too long, become gritty and lose flavour, but Marie Louise may be permitted to hang as long as it will without suffering any deterioration from that cause; but whenever it is decided to leave them on the trees longer than usual, it will be well to draw a net over them to keep off birds, as they sometimes do a deal of mischief by picking holes in the best fruit, and the smallest hole will ruin a Pear, as regards its keeping properties; but those pecked or damaged Pears are very good for cooking or stewing. The small blue-caps or tits seem the most destructive amongst Apples and Pears at this season, and netting up the fruit and shooting the birds seem the only remedies that can be relied on. The season of particular Pears in a scarce year may often be prolonged by gathering them in succession, and by bringing them on in various degrees of temperature—some retarded by being packed in a close jar, and placed in a cool cellar or room; others hastened by being put in heat; but the different kinds should still be taken in succession, as to place a very late Pear in heat too soon would cause it to shrivel instead of ripen. Seasonable time must be allowed for the juices of the fruit to be properly developed. Late Pears should be allowed to hang longer this year than usual, as the leaves are so green the fruits are swelling yet, though on the morning of the 15th inst. the thermometer registered here 5° of frost. The usual indication of approaching maturity, such as parting readily from the stalk, pips assuming a dark colour, &c., are known to most fruit-growers, and may generally be taken as a safe rule. The leaves, too, will furnish evidence as to the right time to gather the fruit, as they are exposed to the same retarding influences.

E. HOBDAY.

SHELTER FOR FRUIT TREES.

THERE can be but little doubt that were the intelligence, experience, and energy of fruit-growers throughout the country brought to bear upon this matter, we might in time, to a great extent, be enabled to ensure a crop of fruit even in the worst of seasons. Why is it, for instance, that in a locality where fruit is a general failure, one may often see a garden or orchard where the fruit trees are bearing a fine crop? Such instances, of which a remarkable one this season came under my notice, are by no means rare. In this district Plums this year were a general failure. One plantation alone presented such a complete and striking contrast to all others as to induce me to carefully note the conditions under which the crop of fruit was produced. In the first place, the garden is situated in the immediate vicinity of a farmhouse, and is sheltered on the north by the buildings appertaining thereto. On the west is a dense wood which sweeps gradually round to the south, but in such a manner as to admit of the trees getting the full benefit of the sun. On the east side, and at no great distance from the garden, are also thick plantations of forest trees. It will thus be seen that these fruit trees are screened from the rough westerly gales, are protected in the most efficient manner from the biting north and east winds—which so often paralyse the functions of the trees, and cause the fruit to drop off, even when fairly set—but at the same time are fully exposed to the full heat of the sun. No better example than this could be found of the manner in which shelter might be utilised in the culture of hardy fruits in this country. Here was afforded ample proof that, even in the most adverse and inclement of seasons, a crop of fruit, and that of excellent quality, might be obtained. These Plums were probably worth more to the grower than ten times the quantity would be in an average season.

By judiciously planting for shelter the climate of the bleakest and most exposed situation might be so ameliorated as to render it no difficult matter to make the production of a crop of fruit a matter of tolerable certainty. In the case of the garden above described there could have been but one cause for its entire exemption from the general disastrous failure. The kinds of Plums were the same as those usually planted in the district, and the soil is of the ordinary description. To the complete thorough manner in which the trees happen to be sheltered must, therefore, be ascribed the bountiful crop which they have borne. What is now required in this country is a system of fruit culture by which we may, to a certain extent, ensure ourselves against those fruit famines which we periodically experience. We are too apt to get either one or several years of glut to be succeeded by a season of scarcity. A good, well-studied system of shelter-planting would, I am convinced, help in a great measure to remedy this defect, and the sooner growers give this part of the subject their serious consideration the better will it be for them and the fruit-consuming public. J. CORNHILL.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Bags Best for Fruit Gathering.—At this season, when the gathering-in of fruit is occupying more or less attention, it may not be out of place to reiterate the desirability of using the greatest care not to bruise the fruit, as if meant to keep any length of time the smallest bruise is sure to cause premature decay. In many parts of the country gathering baskets are used, but about here good large bags, made of stout sacking or hop-pocketing material, are generally employed, and they are certainly preferable to baskets, as there are no hard or sharp edges to bruise the fruit. The bag is slung over the back of the gatherer, and by this means when on a ladder both hands are free to gather and drop the fruit into the bag. Anyone using these bags will never again use baskets.—J. GROOM, *Linton*.

Apricots for October.—It seems impossible, but so it is; we gathered none this season till towards the end of September, and we gathered our last only a few days ago. Few of them have had much flavour, thus they have not merely been out of season, but also very inferior in quality. Neither is this much to be wondered at. A wet cold summer is hardly the weather to develop quality in Apricots. The colour is golden, as usual, but the delicious aroma is wanting. Still they are welcome, as usual, for the dessert, and perhaps all the more welcome for their rarity. Probably of all our fruit trees the Apricots have suffered most. Many fine healthy trees have been utterly wrecked and ruined—almost all have been crippled. It is rather difficult to know what to do about Apricots. It is easy to advise more shelter, or the growing of them under glass; but Apricots too often resent both plans, by simply casting off their fruit in the most efficient manner. They are most impatient of coddling, and seldom yield a full crop under glass. Perhaps the better way will be to try diagonal cordons. These can be planted within 18 in. of each other, and will furnish the walls with so much root

power that should one or several trees fail the loss of space will be trifling, and may soon be refilled. Planted and trained in the usual way, the loss of several Apricot trees creates a serious blank in the walls, and is a great loss to the grower.—D. T. F.

Root Pruning.—Mr. Groom says (p. 347) that "root pruning" might, in most cases, be remedied by our circumscribing the root-space so that the roots could not again descend into the cold substratum, or extend further than was found necessary. This does not differ from root-pruning in principle. Does not root-pruning limit the rooting space and prevent the roots from "extending farther than is found necessary," and I know of no other way of doing this, in the case of plantations of fruit trees, except by root-pruning in the usual way; but it seems Mr. Groom would box off his orchard trees in brick pits like the inside Peaches at Floors; Mr. Groom has, in short, virtually and fully conceded all that I ever contended for. But I would like to know the eastern and western counties of England, where the soil "is light and warm, and far better suited to the production of fruit trees than Kent." Does he mean the deep, heavy, clayey loams of Lincolnshire and East Yorkshire, where in plenty of instances you can push a spade over the head, handle and all, without meeting obstruction? or the cold, blue clays of Durham and the coal districts? or the same in West Lancashire and Yorkshire? Does he mean the dripping climate of the north-west of England or the heavy lands of the west of Scotland, where the rainfall is still greater? It is a trifle too late in the day for Mr. Groom to try to persuade us that root pruning can be dispensed with under such conditions, or that either the soil or the climate of Kent is less suitable to fruit culture than the counties above named, or any others, after what we know of its capabilities, and what Mr. Groom has himself told us on former occasions.—J. S. W.

Green Chisel Pear.—An adverse season often has the effect of bringing into prominence certain kinds of fruits and vegetables whose merits in ordinary years would hardly be fully recognised. The experience of this season will tend to prove that the Chisel Pear is one of the most valuable and reliable varieties that we possess, and I would strongly urge intending planters to include it in their list. More especially would I recommend it to those who may have a cold damp subsoil, or soil of a character not wholly favourable to the growth of the Pear, with which to contend. With the exception of the old Perry Pear, it is almost the only kind bearing a full crop in this district, and many instances of its capability of bearing a crop of fruit under very adverse circumstances have lately come under my observation. In some cases I have remarked trees loaded with fruit when surrounded by many other kinds of both Apples and Pears on which scarcely a fruit could be found.—J. CORNHILL.

Small Fruit Trees.—Wickham Pippin Apple and Knight's Monarch Pear are apparently well suited for those whose gardens do not admit of the culture of fruit trees of large dimensions. Quite miniature trees of both kinds have borne good crops this season in the gardens at St. George's Hill, Byfleet. I would recommend these two varieties to the notice of owners of small gardens.—J. C., *Byfleet*.

Peach Training on the Extension System.—Noticing (p. 348) how strongly "J. S. W." advocates this system, may I ask for information as to what is meant by extension, for unless a tree is crippled through want of space or barbarous pruning, it must naturally extend itself. Mr. Coleman tells us (p. 329) that the giant Peach trees at Floors carry annually one Peach to a square foot. Surely that must be a mistake, for, to say the very least of it, it cannot be called a crop.—T. COWBURN.

Gardening in the City.—Within the purlieus of the ancient Charterhouse, that fine old institution which Thackeray has so truly immortalised in his novels, there is year after year an attempt made within its courts at floral decoration. There is, perhaps, as much of sunshine and warmth, and perhaps of shelter, as is to be found anywhere else in the City, but some dread spell hangs over the place, and flowers of all kinds put out in beds in spring soon wither and die. Yet the Grass lawns are green and fresh, Mulberries ripen their fruit, and we have seen well-grown Chrysanthemums there. Fuchsias, too, seem to thrive, and large numbers of these grown in pots are during the summer placed singly against the cloister columns, to give a little life and cheerfulness to the dingy brickwork. The sorts are chiefly old, and many of them probably in the present day almost unknown. Ivy is also a favourite climber, but as it is evergreen it lacks that freshness and vigour that is found in the deciduous Fig, which grows with great vigour, but does not fruit. Much sooty incrustation may be seen on the walls, therefore in such a situation gardening must of necessity be full of difficulties, but still everything possible is done to give to the old brethren in this establishment some little taste of the beauties of the country in their brick-enclosed habitation.—A. D.

GARDENING FOR THE WEEK.

Conservatory.

THE amount of bloom here at present will unavoidably be smaller than at any other time during the season. This is always the case until Chrysanthemums come in, but where a sufficient number of Camellias exist to admit of their growth being so regulated as to have a portion opening their flowers about this time, not only will they be found most useful for cutting, but, when in a healthy thriving condition, furnished with plenty of foliage, the combination of leaf and bloom which they possess makes them second to no plants in cultivation. The autumn-flowering Veronicas, too, that were lifted and potted some weeks back will have got sufficiently over the check sustained thereby to admit of their introduction here, where their bluish-lavender tints will be an acceptable feature now for many weeks. Amongst hard-wooded plants of the easiest possible growth that flower at this season may be named the Croweas, which, although never making such a display at any one time as some plants will, still nevertheless keep on producing their pretty pink, star-like flowers to the end of the year. These with *Tetratheca verticillata*, the red-flowered *Leschenaultias*, *Cassia corymbosa*, and some of the *Correas*, will help to relieve the sombre appearance of the green foliage, which at this time predominates. It is now also that plants grown both as standards and in bush fashion of *Habrothamnus elegans* and *Heliotrope* will be found most useful; the little extra warmth kept up here will assist the free development of their flowers. These, in company with other quick-growing subjects, though not requiring the assistance of manure water nearly so much as during the principal growing season, will nevertheless be benefited by a weak application once a fortnight. The autumn-blooming *Salvias* will likewise be available, and will bear standing closer amongst larger-growing plants without their close contact being of so much consequence as in the case of plants not grown up from cuttings annually. Any old examples of *Primulas* that have been kept on from last year will be useful for standing interspersed about the house. Where good healthy examples of Oranges exist there is no period of the year when the appearance of their fruit in its different stages is more acceptable than during this scarce time for flowers. *Solanums*, also, where sufficiently early to even have a portion of their berries assuming the ripened colour, will be of service. The many fine-leaved plants it is necessary to introduce at this season to give conservatories a furnished look should be kept scrupulously clean; the washing and sponging consequent upon this have the double advantage of keeping the leaves in a slightly condition and freeing them from insects, which, where even the highest keeping is maintained, entail more incessant labour than anything else connected with plant cultivation.

Greenhouse.

Tying Hard-wooded Greenhouse Plants.—This work is not absolutely necessary to be done in the early part of the winter, but still it is not well to delay it later than can be avoided, inasmuch as where all such operations can be got out of hand as early as possible, there is more leisure for paying attention to other things as these come on. To those who have not had much experience with the work I would urge the necessity for as little injury as possible being inflicted on the roots, to avoid which, as I have before suggested, the new sticks should be inserted in the holes that have been occupied by the old ones; in all cases do not draw the ligatures so tight as to leave any danger of the shoots growing so as to get injured before the material used in tying either has to be removed, or gets so far decayed as to give way if the growths expand to stretch it. Previous to tying, all plants that are subject to mildew should be examined to see that they are free from this pest, and where found, either dust with sulphur, or syringe with water impregnated with sulphur; and all should be freed from any insects that may exist upon them, as the loosening of the branches before tying gives an opportunity for doing this work more effectually than after the training is complete. Loop as many shoots as possible into their positions, so as to furnish each specimen, large or small, evenly over with shoots; by which means fewer sticks will be needed, and yet the untidy condition of the branches lopping about be avoided. It used to be the custom with hard-wooded plants when the tying was completed, to loosen up a portion of the surface soil with a pointed stick or similar contrivance, which, when removed, was replaced with new, under the impression that this was a benefit to the plants, and to give them a neater appearance; but so far as the former is concerned nothing can be more erroneous, as healthy plants invariably have the soil near the surface of the ball full of active roots, that in the removal cannot avoid being injured; and so far as the new soil being an assistance to the plants in the way of a stimulant, this can be supplied to any extent by manure water, or concentrated manure applied to the surface when the plants are making active growth, which is just the period when it is most required and most

effectual; and independently of this, the unnatural covering of the strong roots immediately proceeding from the collar, which invariably takes place when the above course is followed, has the worst effect, and, I feel convinced, causes the destruction of numbers of plants that would otherwise be healthy. A word as to the material of which the sticks are made and their colour: there is nothing lasts so long, or in the end is so cheap, as home-made sticks from the heart-wood of the best Baltic Deal, quite free from knots, such as the lath-makers use. The commonest plants should never, as we sometimes see them, be supported by unpainted sticks. The colour of the paint used is best of a neutral shade of green such as will be least observable, as the less of this work visible the better.

Cyclameus.—Pay every attention to these, both the older plants as well as those raised from seed, which have not yet flowered. Where there is not the means at command of growing them in a pit or small house, either wholly by themselves, or where the temperature can be regulated so as to make their requirements the first consideration, if a few could be moved to a position where they can be kept at about 45° in the night, with a day temperature proportionately higher than that of an ordinary greenhouse, they will come earlier into bloom.

Chrysanthemums.—In autumns like the present when Chrysanthemums in most instances are very late, there is often a difficulty with them where sufficient and suitable accommodation does not happen to exist, especially in the north of the kingdom where, without some protection, it is not safe to trust them out-of-doors even so late as this; for although hardy, still blooming as late as they do, if their advancing buds are subjected to many degrees of frost, I have seen them severely injured. On the other hand, they do better with more air than at this season is given to an ordinary greenhouse, for if kept at all close it has the effect of drawing out the flower shoots weakly, and if any mildew is present upon them the absence of a free admission of air day and night tends to cause its spreading, and if put in houses, already in many cases too full of other things, the Chrysanthemums not only get injured themselves but do harm to other plants as well. Where there happens to be a Vinery that is started early, the Vines, as a matter of course, being now denuded of their leaves, it will be just the place for them for a few weeks until their flowers are about to open, leaving plenty of air on night and day unless there is an appearance of sharp frost. A place of this kind not being available, I have found an improvised contrivance, such as spare hotbed lights put over a temporary framework up to a south wall, with a loose piece of canvas or mats that can be put up in the nights to protect the ends and front, answer all the purposes required. Glazed lights being wanting, an ordinary blind, such as that used for shading plant houses in summer, working on a roller so as to let down in the nights and expose them in the day in fine weather, is the next best thing to resort to. Continue to thin out the buds as they get large enough to lay hold of. Much thinning of the flowers for ordinary use is looked upon by many as unnecessary, but this view is far from being correct, as in the case of plants only wanted for decorative purposes if the flowers are reduced to, say, one-fifth of the number formed, these will be very much better than the greater quantity which would be less fully developed, and individually not possess near the substance to enable them to last long which the thinned examples have. The almost continual rains have much reduced the amount of hand-watering these plants have required whilst in the open air, correspondingly limiting the opportunity of assisting them with liquid manure. They will now be benefited by stimulants of this kind altogether, but for the benefit of young growers it may be observed that although Chrysanthemums are exceptionally gross feeding plants and enjoy much more moisture in the soil than most plants will bear, still it will not do to keep them too wet or the roots will be damaged. Whatever stakes and ties are necessary should be given them, for such giving the preference to dry Willows or Hazels rather than painted sticks or the ugly deal often used without paint. Keep a look-out for mildew and dust any affected leaves that are detected, or it very soon will spread with a rapidity that will render the plants bare and unsightly at the time of blooming, with a proportionate weakening influence on the flowers. Should worms have got into the pots let the soil get a little dry, and then give a good soaking of clear lime water, which will dislodge them.—T. BAINES.

Flower Garden.

Auriculas.—"Delta" seems determined to have the last word respecting the woolly aphid. I know the pest well, have seen and examined it, and never mistook it for mealy bug. I am continually getting plants from places where I know that it exists; indeed, I have had a plant sent me the roots of which were stated to be affected with the woolly aphid. I treated it as I do all plants under similar circumstances, and as I have recommended to be done in THE GARDEN. By such means, so far, the pest has not been able to establish itself here. Some of our best growers and exhibitors have been

troubled with it, and have destroyed it in the way which I have recommended; they are thus able to exhibit and take prizes notwithstanding its attacks, which it seems "Delta" is not. A good grower, writing in a contemporary last week, says it is no new visitant, but he, like many others, states that "it is easily kept in check," and that it will not of itself materially injure a plant unless aided by some other form of neglect. I have just read Mr. Horner's remarks in a contemporary in 1877, where he gives the very same directions for its destruction which I do. His words are "the simple solution of soft soap is enough." I read that one grower soaks his plants in paraffin solution until the soil smells strongly of that oil, but it is impossible for valuable plants to succeed in such soil. Clear your plants of the pest; then clean them of the substance that destroyed it, and then replot in fresh soil. Let this be done, even if it should be midwinter.

Carnations and Picotees.—I have just seen Mr. Dodwell's collection at Clapham, which must certainly be considered to be by far the largest and best private collection in Britain. It not only comprises all the best named sorts in cultivation, but also the largest and best lot of seedling varieties in the country. They were layered as early as possible, and yet the percentage of unrooted layers is much larger than that of rooted ones. Those therefore who have but small collections will have a difficulty in obtaining plants. It is also a question where the store pots can be placed. Our own plan, when it is found that the layers are not rooted, is to pull the old plants out of the ground. If it has four layers all callused but without roots, then I cut the plant down the middle with a sharp knife, leaving two layers and a portion of roots to each division. The two layers are potted in a 3-in. pot, the same as if no roots were attached; thus treated, it will be found at potting time that these have rooted from the callus, and are in as good condition for potting as the earliest rooted layers.

Dahlias.—What a glorious October it has been for these; they are flowering as I write in the greatest profusion. We could ill spare any of them, either double or single, but the latter are most useful for decorative purposes when cut from the plant. Paragon it seems is merely a variety of *D. variabilis*; but be that as it may it reminds us of the beautiful single flowers about which some of the old florists yet alive can speak. The colour, size, and shape of the ray florets are beautiful in the extreme, and if flowers of similar merit could be obtained now, they would be as eagerly purchased as Paragon has been. Dahlias have not suffered in the least from frost as yet with us, and it is still necessary to tie out the stems, and to see that the ground is kept neat and clean underneath them.

Gladioli.—These, like Dahlias, still continue to produce flowers, but the cold nights are rather more trying to them than to the Dahlias. While the weather is dry the bulbs may be left in the ground, but it is well to see that they are taken up should a change occur. The ground intended for planting next year should be prepared at once. I have left this sometimes until midwinter, but found that they did not succeed nearly so well as when it was trenched earlier. I use rotten manure very liberally, but always trench it at least 6 in. below the surface. My plan is to trench the ground two "spits" deep, shovelling the loose earth out each time as well. I give two layers of manure—one in the bottom of the trench, the other when a spit and shovelling of earth have been laid over it.

Phloxes and Larkspurs.—I do not cut the stems of these over while the leaves are still green, but as soon as they decay they may be cut over close the ground. We have cut over the Larkspurs, but the Phloxes are still intact. See that the ground is kept clear of weeds, and that the hoe is worked amongst the plants when the ground becomes hard on the surface.

Tulips.—Ground for these must now be prepared, as planting time is at hand; the surface of the beds cannot be turned over too often when they are dry. Look over the bulbs and see that they are in good condition. Some sharp sand and good rotten turfy loam should be in readiness.—J. DOUGLAS.

Indoor Fruit.

Pines.—In order to maintain Pines in vigorous health throughout a long winter, it is essential that every ray of light should, if possible, act directly on the plants; they should therefore have plenty of space, be kept well up to the sashes, and the latter should be kept scrupulously clean; moreover heavy firing must be avoided, or they will draw up weakly—a stocky growth being ever the most fruitful—and, as the plants are to be kept near the glass, night coverings are indispensable. The labour of applying them is comparatively small, the benefit great, and the saving in fuel considerable. Frigo domo is the most suitable and economical covering I have yet found, and it can be had from the manufacturer's in any length or width desired. Swelling fruit may still have weekly supplies of guano water given them, but all other plants, whether in pots or planted

out, should now have only sufficient clear water to keep the soil moist, *i. e.*, neither wet nor dry.

Vines.—The finer weather that has lately prevailed, though sunless, has been drying, and has wonderfully assisted the ripening of Grapes, seeing that fire-heat could be applied with free ventilation. Such treatment should still be continued till the fullest maturity is ensured, and then there will be no fear that the Grapes will not keep, provided, of course, they belong to the late-keeping class, such as Lady Downe's, Alicante, Muscat of Alexandria, Mrs. Pince, Gros Colman, &c. As soon as fully ripe the only essential condition to good preservation will be to keep the atmosphere dry, and always a few degrees higher than the outside temperature, which will be certain to hinder the settlement of moisture on the berries. Inside borders should now be covered up either with mats or dry straw, and this covering will at once prevent the rising of damp and the necessity for further watering which is now undesirable. Earlier and thin-skinned varieties of Grapes are sure to keep very indifferently this season, seeing that both ground and atmosphere are surcharged with moisture, and therefore if there is convenience to put them in bottles it would doubtless prove a wise proceeding. They would keep well in any dry room from which frost and damp can be excluded, and in cutting them all the wood in front of the bunch should be left on, as this serves, as it were, as a safety valve to prevent too much water being taken up by the berries. There is also another reason why such Grapes should now be cut, and that is the well-being of the plants that have, in many cases, to be wintered in Vineries, and which, till the Grapes are used, have to be kept too dry. Plants and ripe Grapes cannot by any possibility be made to agree satisfactorily together. Vines that have shed their foliage should be at once pruned—indeed, we never wait for this, but as soon as the wood is hard and brown, and the foliage, so to speak, has put on its autumnal tint, then we prune, believing that early pruning tends to induce earlier rest; this done, the houses should be cleaned, and if necessary repaired and painted. The borders should then be top-dressed and mulched.

Peaches and Nectarines.—Keep the earliest houses as cool as possible in order to induce effective rest in the trees, which ought, ere this, to have had their final pruning or thinning out of the shoots. The borders must not be allowed to get dry, and as soon as the time arrives for starting the trees into growth water must be given them in a tepid state, and in sufficient quantity to soak every particle of soil. If the drainage be good there need be no danger of over watering; at all events, it is better to err on the side of giving too much than too little. Remove the lights from succession houses, and prune them also as soon as the foliage has fallen. Strong growers should have their roots disturbed by opening a trench a reasonable distance from the stems, and cutting off a portion of the roots, especially the strongest. This will have the desired effect, that is, repression of growth and more certain fruiting. From careful observation my impression is that we do not make our borders for Peaches and Nectarines sufficiently firm, as I have never yet seen other but fruitful growths on trees that are near walks or that have been left undisturbed in hard borders, except so far as relates to the application of surface mulching or manure waterings during the growing season. Hence, when root-pruning is necessary I strongly recommend that the trench made be filled in by ramming the soil as hard as possible; and in making the new borders the same rule should be observed, particularly in light soils; of course in stiff soils less ramming would be required. The trees in late houses are yet very backward as regards maturity of the wood; therefore keep the lights on and the air as dry as possible, applying fire-heat, combined with ventilation, when the weather is dry. A few days of such treatment will suffice to harden the wood, and then the house may be thrown open and the trees pruned as soon as the foliage has fallen.

Figs.—Trees in pots that were placed in the open air for rest ought now to be got under cover, but still kept cool; and those of them that are intended for early forcing should have 2 in. or 3 in. of the old surface soil removed, and replaced with rich compost, consisting of good fibrous loam, bone dust, and rotten cow manure. If summer pinching or stopping has been practised no pruning will be required unless the spurs are getting too crowded, and if such be the case they may now be cut off. About the middle of November it will be safe to start a first batch, and they will start all the more kindly if they can be plunged in a bed of fresh Oak leaves; not that bottom-heat is really essential to their success, but time is gained by its use at this early season. Trees planted out which have been cleared of fruit may now have more air when the weather is dry, and if the wood be still green artificial warmth would prove beneficial. The border must now be kept on the dry side, and air-moisture entirely withheld, so that in wet or very damp weather it will, for the present at least, be advisable to keep the house closed.—W. W.

Kitchen Garden.

As long as the present dry weather continues every moment that can be devoted to stirring the ground amongst growing crops will materially assist to consolidate a growth that will the more effectually carry them safely through the winter. Lettuces, Onions, Carrots, Turnips, and Spinach will all be much benefited by the bestowal of such labour. The weather is also most suitable for finally earthing up the earliest Celery, tying up a quantity of Endive for blanching, and moving and heeling in the same, either in frames or in some sheltered nook, where temporary protection can be easily applied. Root-storing can also—whilst the weather is dry—be more expeditiously done than when it is unfavourable. Salsafy, Scorzonera, and Beet ought now to be stored in dry sand in a cool shed, or else in clamps the same as Potatoes. Beetroot is sweetest if wintered where it is grown, but protection must be afforded it, which is sometimes inconvenient. Carrots we prefer to house and keep as dry as possible; the wet weather has caused some of them to split, and in storing pains should be taken to keep these apart in order that they may be used first. Parsnips should always be left in the ground till required for use, as the severest frost does not harm them in the least, and the difference as regards their flavour is much in favour of wintering them in that way. Jerusalem Artichokes are yet very puny and immature, and as they bear frost well they should be left in the ground for some time longer. Globe Artichokes ought now to be divested of all old stems; the ground about them should be cleaned and partial protection afforded the stools by means of old tan or Cocoa-nut fibre. Select a few of the most mature crowns of Seakale for a first batch, and other roots may be dug up and again heeled in to induce partial rest before forcing. Asparagus plots may now have a final clearance; cut the stems off to the ground line, then weed, and afterwards stir the surface soil with forks to a depth of 2 in. or 3 in., and the first hard frosty morning give a good dressing of the best manure available; of course those roots that are intended for the present season's forcing need not have manure applied to them. Cabbage, Coleworts, Cauliflowers, Lettuces, and Endive may all still be pricked out, selecting only the most sheltered spots in the hope of wintering them successfully. The unusual severity of last winter, by destroying so many of these kinds of plants, has after all proved beneficial in teaching us to be on the alert with protection for the coming winter. For the sake of neatness clear away all refuse vegetable matter as soon as the crop is exhausted, and let the ground be dug, ridged, or trenched as soon as it conveniently can be. Unfortunately, there is a disposition amongst us to let the kitchen garden take its chance, a feeling of some such sort as what matters it about neatness so long as the crops are good and supplies forthcoming. Young gardeners especially should guard against imbibing such a notion, for neatness ever stamps the character of a gardener.—W. W.

Extracts from my Diary.—October 27 to November 1.

FLOWERS.—Taking down *Clerodendron Balfourii* from roof of stove and placing it on balloon trellis for flowering. Tying small plants of *Azalea*s for forcing. Re-arranging plant houses. Potting old plants of *Alternanthera*s taken out of flower beds for stock. Pulling up *Echeveria*s out of beds.

FRUIT.—Digging up Raspberry suckers to make new plantations. Pruning early Peach house. Pruning Raspberries, and clearing all rubbish off the ground. Gathering Quinces, and storing them in fruit room. Getting pot Vines into Vinery preparatory to forcing. Going over late Grapes and cutting out diseased berries.

VEGETABLES.—Scrubbing, white-washing, and painting Cucumber house, and preparing for French Beans. Earthing up Celery when sufficiently dry. Trenching south border for spring cropping. Sowing Mustard and Cress. Clearing Pea ground and manuring it ready for digging. Sowing Osborn's Forcing French Bean in boxes. Gathering Scarlet Runners for seed. Planting Early London Cauliflowers, five under a handlight in sheltered corner. Tying, thinning, and stopping winter Cucumbers. Digging up roots of Mint and Tarragon, and placing them in boxes in gentle heat. Digging 10 lb. of Ashtop Potatoes from frames planted in July.—R. GILBERT, *Burghley*.

The Globose-seeded Phænospërma (*P. globosa*).—This is a very distinct new ornamental Grass, producing an erect tuft of broadly-lance-shaped leaves, which are bright green above and glaucous below, with prominent ribs. The panicles rise above the foliage, and consist of several whorls of branches bearing globose spikelets. It grows to the height of 4 ft. or 5 ft., and is a native of China.—G.

TIME TO SOW AND PLANT IN LATE DISTRICTS.

At one time gardeners adhered closely to times and dates in all their operations; but modern practice has shown that experience gained in one part of the country, or even in one locality, is almost useless in another, regarding the dates of sowing and planting. It is this fact which renders all calendarial instruction relating to these points of so little value in outdoor operations. In offering these few hints on the above subject, I had better explain that by "late districts" is meant such as are often found in high-lying exposed tracts north of the Trent and in Scotland. Our own district is a late one, lying on the northern borders of Derby and Nottingham, and to which the instructions generally given in reference to cropping of both farm land and gardens do not apply, but, on the contrary, would lead one very much astray. For instance, it would not do for us, nor for our neighbours, to plant the earliest Potatoes sooner than the beginning of March, and late crops are soon enough in by April; many large breadths are not, indeed, planted till May. Yet these late crops, I have noticed for many years back, are always good, and often the best; growth is not retarded but commences strongly at once. From what we have seen of Potato crops at different times throughout the north of England, I do not err, probably, in saying that April is the planting month for the greater portion of both early and late crops.

Another important garden crop is the Onion. Gardeners are very particular about the period of sowing this crop; and some good cultivators maintain that the main crop should be in the ground by the end of February, or, at the very latest, by the middle of March. These dates are right, no doubt for the neighbourhood of London and farther south; but in the north of England the crop is quite safe in many places if the seed be sown by the middle of April, at which date and later we have often seen it got in, and a good crop result. Early sowing may do in early seasons; but these are the exception, and not the rule. It is the same with Peas. Some sow in November; but little or nothing is gained by the practice, as may at any time be proved. Crops sown in February or March are scarcely behind November-sown crops; while it is certain that the same kinds sown in pots in March, and planted out in April or a little earlier, beat them, and the trouble of looking after the seeds for months, to preserve them from vermin, &c., is altogether obviated. In late localities no plan beats the system of sowing in pots. Seed is soon enough in the ground by February at the earliest; but the main crop of Wrinkled Marrows should not be sown till about the beginning of April. Here we find it needless to sow earlier, as the seed rots in the ground, and the later batch—which is sown from the beginning to the middle of May—is always the best, producing the finest crop. During the past spring the first crop of Marrows, sown at the usual time, mostly failed, or were at least a thin crop; but the same seed sown a month later did well. All the tall-growing and finer Wrinkled Marrows are much tenderer than the early round-seeded kinds—a fact not sufficiently borne in mind by inexperienced amateurs and cottagers, who sow all sorts about the same period; if late well, and if early with unfortunate results, and probably blame to the seedsmen.

Perhaps more lamentable failures occur in Carrot-sowing than in any other crop. There have been many complaints of failure this season caused in the majority of cases, no doubt, by the state of the ground. Carrot seed lies long in the ground before germinating at any time, and, if the soil happens to be cold for the season, as likely as not it will rot. We have heard of cases this year, both in the north and south, of crops being sown three times without success. In the north, April is soon enough to sow main crops; but seed may be sown till the middle of June in emergencies, and later if the Early Horn varieties are used. Turnips, on the other hand, are not at all affected by cold—that is, the seed. It will lie in the ground without growing, but will soon vegetate when heat comes. The worst thing about early-sown Turnips is their liability to run to seed, particularly when they experience a check by frost or cold after having germinated, as many early crops are almost sure to do. As to Beetroot, in favourable districts it is unwise to sow before April or May, as the plants are liable to run to seed, or to become rather stringy and hard by autumn—in other words to ripen; but here in our later clime, we may sow in March, and fear neither of these evils. In some late parts the season is not too long for Beet, which should be got in early in April, in order to secure good roots. French Beans are an uncertain crop in cold districts, and in late cold seasons like the present. Standard authorities recommend Scarlet Runners to be sown by the first of April, being hardier than the French Bean, which it is said should be planted two or three weeks later; but here and elsewhere in the north it is found quite soon enough to sow the first at the beginning of May, and the Kidney Beans at intervals till the end of the month. Sooner than that it is seldom worth while to sow, as the seed simply perishes, and never attempts to vegetate. Until the ground reaches an average temperature of 50° it is almost hopeless to expect such tender seeds to germinate freely.

We now come to the important Cabbage tribe, and Cauliflower, Broccoli, and Brussels Sprouts in particular. It is safe and advisable to sow the first outdoor sowings of the former in a favourable situation early in February, putting in small quantities at a time, and at intervals of a week or a fortnight till April, when sowing once a month will be sufficient. Some gardeners sow their Broccoli twice—about March and again in April—in the hope of having a succession of heads during the ensuing winter; but we have tried the plan, and always found both sowings to come in at the same time. We therefore now sow the whole crop at once, and as early in March as possible, and plant out at the earliest opportunity. The latter is a far more important matter than the time of sowing, and a succession of crops may be ensured by employing a number of the best varieties that are known to succeed each other. As regards Brussels Sprouts, spring-sown crops cannot be got up and planted too soon. The longer the season these have to grow, the greater will be the crop. Some cultivators, realising this, sow in autumn, or in heat (like Cauliflowers); but that practice is seldom needful, and the plants are apt to run to seed. Under ordinary circumstances, spring-sown crops should produce Sprouts by the time they are needed and fit to use. They are not wanted particularly while summer Cauliflowers are plentiful and other summer vegetables abundant, but they form the bulk of the supply during the winter and spring months. Perhaps there is no more important crop than Parsely, which is wanted throughout the year. When the winter sowing fails through any cause, it is always an urgent matter to get up spring sowings quickly; but when the former succeeds it will generally afford a good supply till midsummer, or longer. The seed, however, takes a long time to vegetate—three weeks at least, even under favourable conditions of weather; so that it is always wise to get spring crops in as soon as the soil is in working order.

Coming to crops that have to be sown in autumn, the reverse rule holds good in late districts—early sowing should be practiced. We find that when early Cauliflower is sown later than the end of July, it is rarely so good as it should be by the time the plants should be under handlights and planted out; but in earlier localities sowing may be delayed until the 20th of August. Tripoli Onions and hardy winter Lettuces require to be sown as early as the Cauliflowers. Cabbages also need to be in about the same date. But though sowing early is advisable when the summer draws early to a close, early planting is not desirable. March frosts do much damage to early Cauliflower plants, and April is soon enough to plant out from the frames, and plants pushed on in pots should not be put out till later. That critical autumn crop, Prickly Spinach, should be sown twice. In late districts the beginning of August is a good time, but a later-sowing may be put in a little later, in case of a very mild autumn following.

J. S. W.

THE HEREFORD FUNGUS FORAYS AND FEAST.

THIS now-much-looked-for reunion came off this year in the first week of October, and, despite the partial inclemency of the weather and adverse character of the season, brought troops of friends to the mycological metropolis of Hereford. The promised visit of the eminent French mycologists, MM. Cornu, Quélet, and Emile Boudier, inspired a zeal in the chief English honorary members of the Woolhope Club to be present on the occasion, and in addition to Messrs. Broome, Cooke, Remy, Phillips, Spencer Percival, Vize, Plowright, Houghton, and other well-known faces. The venerable form of Miles Berkeley was hailed by the enthusiastic fungus-folk at the soirées and some of the excursions of the week. One of the most agreeable of the latter was to Cabalva, the residence of Mr. Broadwood, near Clyro and Whitney, just over the border in Radnorshire; another to the old rendezvous of Dinmore Hill; and, in spite of weather, persistent hunters brought back to Hereford vascula so well filled, as to ensure a more than average show of Agarics in the Club room. The great foray of the week was, however, that of Thursday to Foxley; and, though it opened untowardly, and the woods were hopelessly wet and unfavourable to the game in hand, even the stragglers and camp-followers must have been compensated for the walk to the top of Lady Lift by a gleam of glorious sunshine, affording a perfect panoramic view of west, south, and north Herefordshire. A knot of Woolhopians who, forsaking the scrutiny of mycologic treasures *sub pedibus*, pushed on from Lady Lift to the grand eyrie of Garnstone point, were rewarded by one of the most picturesque of near views, in a glimpse of the old world town and towering spire of Weobly, just beyond the underlying Garnstone Park and Castle, and opportunely framed for the occasion in a perfect rainbow. Seldom does the sightseer or hill climber find such account for his toil of feet and knees and hands; but in the valley below were nestled Herefordshire churches, such as Sarnesfield, where John Abel, the builder of so many characteristic black and white timber houses,

sleeps well and meetly in the churchyard, and between Garnstone Point and it the old typical timber-house of the Ley is seen to avouch him the architectural *genius loci*. The stragglers had to plod back through bracken, and over brake, bush, and scar, until by a precipitous and clay-sodden path, they reached in due train-time the Moorhampton Station, made their way back by railway to Hereford, and, after official business at the Rankin Museum, adjourned to the "Green Dragon" for the feast, at which the Woolhope President, Arthur Armytage, Esq., of Dadnor, presided. He was supported by the Rev. Miles Berkeley (the Nestor of Fungology), Sir William Guise, Mr. Pyper (the President of the Malvern Naturalists), Mr. Broome, F.L.S., and others. On such an occasion, as was meet, the tables were so arranged that guests from across the channel found nearest them the very Englishmen who could converse with them most facetly in their own tongue, and Dr. Bull's praiseworthy endeavours in interpreting to the French cryptogamic botanists the enthusiasm of their English *collaborateurs* were admirably seconded by the finished grace of Dr. Steele's speech in the same language. Mr. Berkeley addressed the assemblage, which numbered eighty fungus-eaters, in a speech as full of instructive as of interesting matter germane to the occasion. The French guests severally responded; and in the course of the evening several excellent papers were read. Those who are enriens to dive into the mysteries of these now familiar orgies will be glad to learn that of mycologic food or edible fungi only chopped and stewed Chanterelles were served, and that the possibility of casualties was minimized. Report averred, indeed, that the danger was either of starvation from cold dishes, or from defect of due attendance; but such was not our experience, beguiled perhaps "by the feast of reason and the flow of soul;" and, indeed, even if the bill was a true one, the excuse might have held good that but fifty gave in their names to dine, and upwards of eighty attended. After the sole toast in ordinary of a most loyal club and county had been duly honoured, and a few exceptions to the general rule allowed in compliment to distinguished guests, the intellectual food of the evening commenced in a paper by Dr. M. C. Cooke, "Croutes aux Champignons," into which was thrown all the humour calculated to gently wean a well-dined audience from grosser tastes and viands. Mr. Percival followed the lead in a lively and practical paper on the "Influence of Situation, Soil, and Season on the Growth of the Larger Fungi," the "three S's," as he christened them, of Fungology; and Mr. W. Phillips also read an equally practical paper on a subject which comes home to every householder, gentle or simple, "On the Fungi of our Dwelling House." This was illustrated by a fine specimen of the *Merulius lachrimans* brought from Scotland. Such papers might of themselves explain the *raison d'être* of the Hereford fungus feasts, their popularity, and the lasting success of the Woolhope Club; but as night drew on and the sojourners in the hospitable city felt the loss, one by one, of the friends who had come to welcome them from the country, the residue adjourned to the *soirée* of Mr. Cam, the excellent treasurer of the Woolhope, where other and more scientific papers were read by Dr. Cooke "On a New Genus of Discomycetes," and "Notes and Queries on British Hymenomyces," and by M. Quélet on "Quelques nouvelles espèces de champignons trouvées en 1879 (Jura et Vosges)." On the previous evening at *soirée* at Dr. Bull's, Mr. Vize had read a very interesting paper on a singular and novel fresh water Alga, noticed by him in a pond within the park at Powys Castle near Welshpool, and the French guests of the club added to the interest of the evening by various papers, one of them also, M. Boudier, by some admirable drawings of curious French Agarics. We have said little of the museum, and its contents, arranged on tables as in former years, but it may be briefly said that most of the accustomed fungus forms were there, Agaricus cæsaricus, fusipes, squarrosus, muscarius, velutipes; Lycoperdons, Hydnum, Pezizas, and Russulas "of sorts," as the nurserymen might say, Mushrooms, and Toadstools.

Prickly and pulpy, blistering or blue,
Livid or starred with a lurid hue,
Agarics and fungi with mildew and mould,
Started like mist from the wet ground cold.

The "wet ground cold," however, did not seem likely to deter the chief visitors of the club from the Continent and the metropolis from prolonging their stay over Friday, when a large party of them were invited to make an excursion to the beautiful gardens and park of Holme Lacy, and to partake of the hospitality of Sir H. Seadmore Stanhope, Bart., besides inspecting the compliment to the French gardeners, which the owner, a scientific horticulturist himself, has paid them in adopting successfully on the walls of his fruit gardens the eordon system of fruit training.

J. D.

For woodland walks where gravel gets green and unsightly even a thin coat of ashes will provide a pleasant means of getting amongst one's floral treasures when wet, slippery soil would destroy all chance of doing so for at least half the year.—JAMES GROOM.

ROSES.

ROSE AVENUES.

The Grass avenue in the nursery of Messrs. William Paul & Son, at Waltham Cross, must be well known to those who have ever visited that part of Hertfordshire, as one end touches the old coach road, and the other end the main line of the Great Eastern Railway to Cambridge. The avenue runs in a straight line east and west for nearly half-a-mile, and the look-out beyond in the direction of Waltham Abbey extends for another mile, where the eye rests on two large Lombardy Poplars and a range of wooded hills rising in the distance. It is crossed by five roads running north and south, reaching far into the depths of the nursery. The Grass path in this avenue is about 12 ft. wide, and at the outset there are on either side circular and oblong beds of Pelargoniums and Roses, with choice Conifers and other evergreen shrubs behind. After passing the first intersecting road the scene is changed. Here are belts of evergreens, composed of the choicest specimens, in which the golden and silvery tints abound in the shape of Aucubas, gold and silver Euonymus, golden Yew, golden Cypress, and Arbor-vite, gold and silver Hollies, many of the latter being handsome round-headed standards. The taller-growing kinds are arranged in the centre of these belts, with many of the most useful and attractive of dwarf evergreens, such as the various kinds of Cotoneaster, Daphne, Holly, Laurustinus, Ligustrum, Osmanthus, Raphiolepis, Skimmia, Yucca, and the like on either side. At the time we write the bright red berries on the Skimmias show in beautiful contrast, and are otherwise very attractive. At the next intersection we meet with another series of beds, where Roses and Rhododendrons are assigned their respective beds, supported behind with lines of pillar Roses. A few formal trees, as standard Hollies, now bright with their coral berries, standard Laurels, which in the distance might be mistaken for Orange trees, standard Portugal Laurels, and the like are introduced here. Another cross road arrests our attention momentarily, the sides being lined with pictorial trees and pillar Roses, and on passing onwards we find ourselves again enclosed in belts of evergreens. We soon reach the fruit ground, and looking to the right and left we see avenues of pyramidal fruit trees of considerable size, many of them, the Pears especially, laden with fruit. From this point are seen numerous beds of dwarf Roses, with lines of pillar Roses behind, which, being skilfully associated with standard evergreens, as Laurels, Box, Golden Yews, and Phillyreas, constitute a very uncommon and pleasing picture. Of the rows planted in separate beds the following are the principal sorts:—Of Hybrid Perpetuals, Alfred Colomb, Captain Christy, Charles Lefebvre, Countess of Oxford, Diana, Duke of Edinburgh, Etienne Levet, Fisher Holmes, Géant des Batailles (covered with beautiful flowers, October 21), General Jacqueminot, Glory of Waltham, La Brillante, La France, Louise Darzens, Madame Charles Wood, Mlle. Therese Levet, Maréchal Vaillant, Magna Charta, Marquise de Castellane, May Quennell, Paul Verdier, Peach Blossom, Prince Camille de Rohan, Princess Beatrice, Rosy Morn, St. George, Victor Verdier, Xavier Olibo. Of Tea-scented kinds there are Devoniensis, Homer, Madame Falcot, Madame Margottin, Marie Guillot, Sombreuil, Souvenir d'un Ami. The above are planted in circular beds, and

for the most part a bed of a sort has been planted with good varieties for massing. In the oblong beds there is a line of a sort of all the best Roses known. The pillar Roses behind and on either side of these beds are the strong-growing varieties of Hybrid China, Hybrid Bourbon, Hybrid Perpetual, Evergreen, Ayrshire, and Noisette. As the whole are pruned with the view of producing masses of good flowers rather than few flowers of large size, the effect of this grand avenue of Roses in full summertime can be easier imagined than described.

ALEXANDRE DE RAR.

An Avenue of Roses.

Roses in Town Gardens.—Complaints have appeared from time to time in your columns regarding the failure of Rose trees in London gardens, that I am induced to give my experience for the last five years at St. John's Wood. The soil, to begin with, was the common clay and mould of most town gardens. I had it well mixed with a load of roal scrapings, which cost me 3s. 6d., and in the autumn with a load of old manure. I brought from the country some dozen Rose trees on the Brier and thirty on their own roots, all young trees. The Rose trees on the Brier have all died gradually off, but I have not lost one on their own roots. I think your correspondents should take a hint from this fact as to the superiority of the endurance of Roses in our damp, smoky London atmosphere when on their own roots. I have what are called strong, vigorous Perpetuals, some of them 4 ft. high, and all in good condition. They have flowered fairly this summer, and the plants show well for the future. No one, however, must expect plants in London gardens to succeed by merely placing them in the earth and leaving them to chance; failure is caused I think by allowing the ground to be too much shaded with trees, and not drained enough. I prevent the latter by digging two spades deep in various places, and throwing in a spadeful of cinder ash; persevere in this way and you will have a fair chance of growing Roses. Lilies (particularly Liliun candi-

dum and Crown Imperials), Fuchsias, Chrysanthemums, Tritomas, Carnations, Gladioli, and various Perennials will all grow well in our London gardens if properly treated.

National Rose Society.—A meeting of the general committee was held, by permission of the Horticultural Club, at their rooms, Arundel Street, on Tuesday, the 14th inst., R. G. N. Baker, Esq., in the chair. The hon. treasurer, Mr. W. Scott, submitted his financial statement, from which it appeared that, after paying all expenses, there remained a balance at the bankers of nearly £130. It was then resolved that the outstanding liabilities to the prize winners for the year 1877, which they had kindly allowed to remain over, should be paid; there would then remain a balance of £60, and the Society is entirely free of debt. It was proposed also that the London exhibition should be held at the Crystal Palace, Sydenham, on July 3. An offer had been made by the Manchester Botanical Society that the provincial exhibition should be held there again, but it was determined that it should be announced that, in order to give opportunities to other localities, the committee would be willing to receive application from any other towns which might be willing to receive the Society. It was announced that Mr. R. G. N. Baker would give a cup, value £10 10s., to be competed for by amateurs; Messrs. Paul & Son a cup, value £10 10s., for Cheshunt-raised Roses; and the proprietors of the "Journal des Roses" a silver medal for twenty-four Roses, three of each, one full bloom, another

half bloom, and the third a bud. The meeting was most cordial, and general satisfaction expressed at the prosperous condition of the Society.

Gloire de Dijon Rose.—There are a few plants of which it may be said that they should be found in every garden, and amongst these may be placed the Gloire de Dijon Rose, the merits of which are too well known to need description. I would, however, desire to remind those who may have a spare piece of wall in a sunny sheltered situation, that they cannot do better than devote it to this glorious old Rose. The Gloire de Dijon is a vigorous grower, and flowers freely in the open air, but if afforded some protection against wind and rain, not only will the blooms be of superior quality, but they will be produced in good condition up to a much later period than when fully exposed to the vicissitudes of the autumn months. The buds and half-expanded flowers are invaluable for bouquets, and are doubly welcome at a season when Roses generally have become scarce.—J. CORNHILL.

Marechal Niel from Cuttings.—Cuttings of this Rose cut across immediately below a joint in the usual way callus freely, but the latter gets so hard that it soon cuts off all communication between the rootlets and the cuttings. To obviate this the method followed in the Handsworth nursery, where this Rose is grown in quantity, is to cut just above a joint, and then take a slice off the cutting, as one would do in making a graft, when roots protrude in abundance from each side of the incision, and a well-rooted cutting, without failure in any instance, is the result.—M.

THE KITCHEN GARDEN.

CAULIFLOWERS.

EVERYONE who has a garden endeavours to grow at least a few of this delicious esculent, but either from sowing at the wrong time or not treating them properly through the winter, they often turn out very disappointing, by what is technically called "buttoning," instead of forming those large, snow-white heads for which they are so deservedly prized. Except for the very earliest cutting to come in during May, I always find it best to sow a few seeds in boxes or pans about the middle of February, and place them where they can get a little heat to induce them to germinate freely. Plants raised in this way, and nursed under glass, are far superior to any that stand about all the winter, for unless taken special care of they are at best only in a half-starved state, and it is these checks they receive that causes them to turn prematurely. The next to succeed the first spring sowing made in the boxes or pans should be sown a month or so later on any gentle hotbed, between rows of Potatoes, or in a frame made up for the purpose of raising an early lot of Lettuce, Celery, Brussels Sprouts, and such like, where they can be drilled thinly in rows, and stand close up to the glass till they get sturdy and strong and fit for handling. My intention, however, is to treat of autumn-sown plants, such as are now in the seed-bed, or pricked out to stand the winter, which, unless in very sheltered situations, are sure to be destroyed by frosts or cold, cutting winds. The plan we adopt, and it is one I can strongly recommend, is to take them up and pot them in 3-in. pots, using a very light, rich soil for the purpose, such as leaf-mould, loam, and rotten manure, in about equal parts of the two former to one of the latter. In this they root freely, and form such a compact ball with their numerous fibres that they may be turned out in the open quarters in March without the slightest disturbance, or the plants suffering a check in any way. To keep them during the winter, there is no place suits them better than a cold frame, where they can be plunged in half-rotten leaves, and have plenty of air whenever the weather is at all favourable. Such a congenial, non-conducting material for the pots to stand in maintains a uniform condition as regards warmth and moisture at the roots, and prevents frost penetrating sufficiently deep to injuriously affect them, for if kept dry, the tops will bear severe cold without taking the least harm. The proper way to admit air is to tilt the lights behind, as then any rain that falls is thrown off, and all draughts or sharp currents are avoided. Unless during a continuance of very sharp frost, covering is not required, and then only just enough to break its full force, as the harder they are kept, and the less cooling they receive the better, and more satisfactory will they turn out. If a warm sunny border can be spared to plant them in, towards the middle of March they may be turned out without risk, and at the end of that month in any quarter of the kitchen garden. Cauliflowers, being, like all the rest of the Brassica tribe, gross feeders, should have plenty of manure worked in the soil previous to planting, and drills drawn for the rows that they may stand below the general level of the ground, so as to be easily watered with sewage directly they get a fair start. With warm weather, it is astonishing what a help this is to them, and how succulent and fine they

always are when well fed with liquid impregnated with manurial matter. As regards those being wintered under hand-glasses, the only way to prevent buttoning is to keep air nearly always constantly on by tilting the top of each glass with a brick; or, better still, by placing them across the corners of the lower half, as then the ventilation they receive is much more regular and perfect. The great secret in wintering young Cauliflowers successfully is in keeping the leaves and hearts dry, and the plants sturdy and strong by a full exposure to light, and without being confined in the way many usually are. The best sorts for spring work are the Early London and Walcheren, the latter being likewise equal to any for turning in during the summer, to be succeeded by that grandest of all autumn Cauliflowers—Veitch's Giant—that never fails in producing immense heads, firm, and well protected from the frost by the close hearing over of the leaves. Any of these now coming in may be kept for a long time laid in by the heels in any light open shed, where they can be protected by having a mat thrown over them at night. S. D.

STORING ROOTS FOR WINTER.

LIKE other produce, most kinds of roots are late in coming to maturity this autumn. Were it not for the danger of being injured by frost, many of them might be left in the ground until the greater part of November was over; but as this would hardly be safe in such a season as the present, no time should now be lost in seeing to the storing of all roots which require protection; of these Potatoes must, of course, head the list. Different modes of storing these are often recommended. Some stack them up in pits, and cover them over with straw and earth; others keep them in sheds, cellars, and similar places, and I decidedly prefer the latter plan, as any kind of root so liable to disease as the Potato should always be stored where they can be conveniently looked over weekly if necessary. Frost must also be entirely excluded. We keep our Potatoes during winter in excellent condition in a shed arranged in much the same way as a fruit room, deep shelves being placed one above the other. Light can be let in when wanted to facilitate the work of looking over the tubers, or the holes can be stuffed up to exclude it, which is necessary in order to keep the roots from becoming green.

Any dark shed or cellar will answer the purpose as well as our Potato house. The roots may be placed on the top of one another to the depth of 1 ft. or more, and when looking for diseased ones this mass should be turned over. When there is danger of frost touching them, they should be protected by straw or hay, and in a place where they cannot be kept quite in the dark, this covering should remain on them always. A hot place for storing all kinds of roots should be avoided. A temperature of 45° will be found quite high enough, and 10° less than this will do no harm; but should it rise to 55° or 60°, growth will soon begin, and no roots start more readily than Potatoes, or are more injured by so doing. All that is required to preserve Potatoes during winter, or for the next six months, may be briefly summed up as follows: Keep them in the dark, in a temperature from 35° to 45°, in a place where they can be looked over weekly. Seed Potatoes may be treated differently. We never trust to what are left over in spring for planting; on the contrary, all our seed is selected before any of the Potatoes are stored away. Those about the size of a small hen's egg are what we like best for seed; and instead of keeping them in the dark they are spread out thinly in any place fully exposed to light. Under such conditions they do not so readily start into growth, or make long white growths so injurious to seed Potatoes when kept in the dark. As in the case of other Potatoes those for seed must be kept cool.

Late sown Turnips of the Chirk Castle and Golden Ball type need little storing in winter, as they are very hardy and keep as well in the ground as anywhere, but when severe weather is expected a quantity of them may be taken up and stored in any shed or out-house. A little straw thrown over them will keep them fresh. Turnips full grown now, and which would be likely to rot in the ground if left after this time, should be taken up at once; the leaves and tap roots should be cut away, and they should be stored in a shed. If there is a quantity of them one half may be put into a triangle-shaped ridge-pit out-of-doors. They must be kept dry and partially in the dark as well as being kept cool, but in every way they are easier kept than Potatoes, at least they will take no harm should they get less attention.

Beetroot if not already taken up should be lifted now. Great care is necessary in doing this as no root or rootlet should be broken if it is desired to have the roots full flavoured, juicy, and sweet. Any breakage causes the sap to leak out and this spoils the root. A fork must be used in taking them up and the leaves must not be cut in nearer to the crown than 3 in. After being taken up they should be spread out thinly under cover to dry, after which they may be stored in any cool dry place. In order to keep them from

shrivelling they should be covered over with dry sand or earth. We generally keep them in a square heap, beginning with a layer of roots packed closely together all over the bottom, then a layer of sand, roots and sand again, and so on until all have been covered.

Parsnips we hardly ever lift out of the ground, as we find them to keep as well in it as anywhere else. As soon as the leaves decay they should all be removed, or they may cause the crowns to rot. Before severe weather sets in a quantity may be lifted ready for use, and those left in the ground may have a layer of straw, leaves, or Fern, put over them.

Carrots should be taken up and treated like Beetroot, except that the leaves may be cut closer into the crown. Late-sown ones, which are intended to be used young, may be left in the ground, and covered over in severe weather like Parsnips.

Onions keep well in any dry room either roped or otherwise. In all cases the roots should be dry before they are stored in any close place, as on this chiefly depends their keeping well; and no roots, especially those in heaps, should be left too long without being looked over, as when one begins to rot the others quickly become affected.

CAMBRIAN.

CHAMPION AND MAGNUM BONUM POTATOES.

I AGREE with Mr. Knight (p. 349) that those who planted the Champion Potato this year will not have much cause to regret having done so. It has done well here, and, as far as I can learn, with everyone in this district who has planted it; but I should say that the weight of the crop is more than thirty tons per acre less than that in Mr. Knight's case; but surely he has made some mistake about even forty tons being obtained from an acre. For my own part I candidly confess that I do not believe there ever was such a crop of Potatoes lifted from the ground, and I am not alone in this belief hereabouts. Forty tons per acre would be equal to a ton from eleven square yards, or sixteen lines 2 ft. apart and eleven yards in length, and each line would require to contribute $1\frac{1}{2}$ cwt. This I venture to assert is incredible with from eight to twelve Potatoes at a "shaw," and I am the more convinced of this as a few days ago I superintended the lifting of two lines of Magnum Bonum Potatoes, which were 23 yds. long—more than twice the length than they would require to be in Mr. Knight's case—and these lines averaged 1 cwt. 20 lbs. and sixteen Potatoes to a "shaw." In some cases more were frequently dug up, and every one fit for table. Each line was 3 ft. apart, and the sets were about 18 in. asunder, and in lifting the crop, when putting in the fork the greatest care was required not to injure the tubers. It will be seen that these lines occupied 2 yds. by 23 yds., or 46 sq. yds., and the weight of the crop was 2 cwt. 40 lbs., this would be equal to 11 tons 5 cwt. per acre of marketable Potatoes; the small ones were not weighed, as they were a mere handful and not worthy of being taken into consideration, and no diseased ones were to be found amongst them. Granting—though I am not inclined to do it—that I might have had a third more of the weight off the same piece of ground by planting 2 ft. apart instead of 3 ft., the result would only have been 15 tons per acre, and these, at £5 per ton, would have been £75 per acre, but Mr. Knight must have realised £200 per acre. As to the size of the Magnum Bonum I might add that a great many of them weighed $\frac{1}{2}$ lb. each, some $\frac{3}{4}$ lb. [Bolls, not tons, were meant. I have no doubt, however, that our crop will yield sixty bolls.—H. K.]

Strange as the circumstance is I can endorse "A. D.'s" statement about the foliage of the Magnum Bonum having died here before the tubers were ripe, a statement which "J. S. W." seems to doubt—the tubers, when I lifted them, were not ripe though the foliage was completely gone and the stems in a good many instances dried up. Paterson's Victoria and White Rocks are quite two-thirds diseased, while the seed has not been left of Regents and Snowflake. The Magnum Bonum and Champion are the only two sorts that have resisted disease here.

JAS. FAIRWEATHER.

Halston.

I can bear out Mr. Knight's statement (p. 349) regarding the immunity from disease of the Champion. We have just lifted a large quarter of it and not a vestige of disease is observable on them. The soil is a deep sandy loam. We have also just lifted another quarter of Magnum Bonum in which no disease is observable, while some twelve other sorts, growing in the same field, are all more or less diseased.—JOHN DOWNIE, *Corstorphine, near Edinburgh.*

The Champion Potato.—I cannot speak so favourably of this Potato as Mr. Knight (p. 349). In the spring of 1878 we had a quantity of seed of it direct from one of the principal Potato dealers in Scotland. Last year, when many kinds of Potatoes were free from disease, the Champion was also quite free from it, but this season, when a variety free from disease is a rare exception, about a quarter of the Champion crop is diseased. Magnum Bonum, growing on the

same quarter, has been quite free from disease, and there are several others with us this season which stand before Champion in this respect. Admitting that Champion is a good disease-resisting kind, its extra deep and numerous eyes will, I should say, be against its becoming a favourite.—CAMBRIAN.

Magnum Bonum Potato.—"J. S. W." (p. 349) entirely misapprehends what I wrote as to the haulm of Magnum Bonum dying off before the tubers were ripe. I referred to the fact that the leaves had gone under the influence of the disease as those of others had, but still there was no disease in the tubers, the stems having decayed prematurely because the leaves had fallen before the Potatoes were ripe. Surely "J. S. W." must admit that hardly a single tuber of any sort has during the present season ripened properly; on the contrary, they have ripened prematurely, because the disease had promoted in the leafage premature decay. Just what Mr. Knight, of Floors, says respecting Champion, I have said regarding Magnum Bonum, and if proof of what I have stated were wanted in addition to my own and market growers' experience of it, it may be found in a statement made in a contemporary to the effect that Mr. James Godden, of Woodstock, a grower whom I know well, has just lifted 500 sacks of it quite untouched by disease. Is not that, this season, a marvellous experience? I am glad to perceive that Messrs. Sutton have, in their new white round seedling from the same raiser, yet another kind even superior to Magnum Bonum in quality, that has this season been absolutely untouched by disease.—A. D.

AMERICAN NOTES

Smalley's Early Defiance Asparagus.—There are those who deny that there are any varieties in Asparagus, and found this opinion upon the fact that Asparagus has its sexes separate in different plants. We do not see why this should hold in Asparagus and not in Hops and Persimmons, the two cases that now occur to us of dioecious plants well known as having varieties in cultivation. That there are varieties of Asparagus sufficiently unlike to make some more desirable for cultivation than others we are as well convinced as that there is a difference in Cabbages, though the difference is not so striking. The young, year-old plants of Smalley's Defiance, or of Colossal, are very different from the common, and we have a kind in the garden for which we have no name, that is entirely distinct at all stages from either. We have been familiar with Smalley's variety for two years, and feel sure, that in earliness and in excellence of flavour, as well as in the proportion of each shoot that is tender and eatable, this variety is sufficiently distinct to make it desirable for both the home garden and for market. We have not mentioned size, as this, more than any other character, may be produced by high culture, but in this it will compare favourably with any other variety.

The "Welcome" Grape.—Mr. Ricketts, of Newburgh, N. Y., whose marked success in producing new varieties of hardy Grapes we have frequently referred to, has experimented with exotic Grapes with no less gratifying results. We recently saw and tasted the Grape to which he has given the expressive name, "Welcome"! as that must have been his thought when he first tasted its fruit. It is a cross between one of the Hamburgs with one of the Muscats, we have forgotten precisely which. The result is the best exotic Grape we have ever tasted. The late Mr. A. J. Downing described one of our native Grapes, the "Elsingburgh," we think, as "little bags of wine," and we know of no better description for the "Welcome" than to say that its berries are "large bags of wine." They are about the usual size and colour of the Black Hamburg, but there all likeness ends. The berries are without pulp or flesh, but melt away in a rich juice, with a refreshing quality, as delightful as it is rare. This Grape must be "Welcome" to every Grapery, and take the highest rank among exotic Grapes at home and abroad.

The Large Cone Flower.—We have for some years had in the garden a southern and south-western species, *Rudbeckia maxima*, or "Large Cone-flower," which is so much unlike the other species that we call attention to it as desirable where there is room for such subjects. This species, extending from Arkansas, its northern limit, through Louisiana to Texas, and being a peculiarly southern species, we are rather surprised to find it hardy; as it has stood the past three winters without protection, we may regard it as hardy for the climate of New York City. The aspect of the plant is quite different from that of any of the more familiar species; while its specific name, *maxima*, indicates that it is large; it is without the coarseness that belongs to the others. The stem, which, according to Nuttall, its discoverer, reaches 9 ft., is with us about 6 ft. high, and simple or sparingly branched above. The leaves are generally ovate, the lower on long petioles, the upper sessile and more or less clasping the stem; all have that peculiar green colour known as glaucous,

or sea-green, of which we have a good example in the Cabbage-leaf, and which gives to this plant one of its most striking characters. The flower-heads are either solitary, at the end of the stem, or the stem branches above and has the heads of flowers on naked stalks 15 in. or 20 in. long. The flower-heads are striking, on account of the peculiar shape of the brownish disk, as the central portion of the flower-head is called. In most of the Composite family the central portion is flat or convex, as we see in the common Sunflower, while here it becomes conical and extends upwards to the height of 1 in. or 2 in., projecting above the few long yellow rays which soon become drooping. Now that the plant has proved to be hardy, its tall stature, its neat glaucous foliage, joined to the peculiar appearance of its flower-heads, will make it desirable in gardens, either in isolated clumps or at the rear of other plants.

Fruit-Preserving Powders.—When fruit preserving powders were first introduced several years ago, we examined into the matter carefully. We are assured that the composition is not essentially different from what it was then, and what was said concerning them at that time is equally true now. The composition of these powders was given to us in confidence, and we are not at liberty to state it. It is a natural product found in several parts of the world, and though it possesses preserving qualities in a much more striking degree than common salt, it is, unlike that, with very little taste, and so far as medical authorities have discovered, it is not known to exert any manifest effect upon the animal system in large doses, while in the small quantity used in preserving fruits, &c., it is, so far as known, practically inert. We have tasted fruits and cider treated with these powders—and have found them well preserved and without unpleasant taste.

Broad-leaved Uniola (*Uniola latifolia*).—This is found from Pennsylvania and Illinois, southward. It grows 2 ft. or 3 ft. high, and has a large, loose panicle, bearing large flattened spikelets, and, when full grown, 1 in. or more long. This Grass seems to be but little known abroad, at least we do not find it mentioned in the recent works on perennial plants. A clump of this Grass in rich garden soil gathers strength from year to year, and when well established is a beautiful object. The loose, drooping panicles have a wonderfully graceful expression when living, and this is not lost when added to a winter bouquet.—*American Agriculturist*.

Common Virgin's Bower.—This lovely Clematis, now in all its glory, draping trees, and spreading over bushes, banks, and rocks, is a common wild plant, to be sure, but there are few more comely garden ones. It grows readily from transplanted roots, layers, and seeds, and for festooning old stumps, fences, and trellises it is admirably adapted. The nakedness of some of our country homes is hardly in conformity with this progressive age, and this is the more to be regretted when we know our woods and waysides teem with plants as fitly suited to adorn a palace garden as to enrich a farmer's yard. The Climbing Hempweed, Ground-Nut, Trumpet-Creeper, Climbing Fumitory, and Wild Balsam-Apple are good examples of common wild but ornamental climbers.

A Butterfly Flower Bed.—Near the rockery in Forest Hill Cemetery is a carpet flower bed, the groundwork being mostly composed of Mexican Cotyledons, and on which, in embroidery fashion, is defined a large and beautiful butterfly, the horns, eyes, long body, and expanded spotted wings all being handsomely and truthfully delineated with such plants as *Alternantheras*, *Cotyledons*, *House-leeks*, *Cacti*, and the like.

Night-blooming Plants.—We all know about the Night-blooming Cereuses, the fragrant Evening Jessamines, and the showy Evening Primroses; but it is not generally known that the long-flowered Tobacco Plant (*Nicotiana noctiflora*), and others of its class are among the brightest and most profuse of evening flowers. Their colour is white.

Japanese Ivy on Tomb-stones.—*Ampelopsis tricuspidata* is being extensively planted hereabout, and although it is one of the best and most appropriate climbers for covering buildings, fences, old stumps, or anything it can cling to, there is certainly a limit to its use. It is not without a feeling of deep regret I see it extensively used in our cemeteries to cover head-stones and monuments. The "Ivy" is planted at the back of the head-stones and encouraged to cover them all but the lettering in front, and even costly and elaborately-carved monuments are being ruthlessly buried in the same fashion.

The Chinese Yam.—*Dioscorea Batatas*, the Chinese Yam or Cinnamon Vine, as it is often called, is one of the best climbers I have tried for high and dry exposures. The Yams bury themselves so deeply in the earth as in a measure to escape the evil of drought. At any rate, we are growing it this year in one of the driest spots of the garden, at the base of a wall, and where all other climbers, except Hops, Mignonette, Vine, and *Rumex sagittifolius*

have almost refused to grow, and in point of thriftiness the Yam surpasses all others but the Hop, which, though taller, is spoiled by insect pests—the Yams are not.—*Rural New Yorker*.

Weeping Privet.—The Weeping Privet (*Ligustrum vulgare pendulum*) has not received due credit. It is unquestionably a fine tree. I confess, however, that it did not impress me favourably for a year or two, as I knew it in the form of one specimen. Its long pendent branches and narrow leaves grew in very unkempt fashion. In other words, its habit was irregular, and not at all pleasing. Yet pruning makes it an entirely different tree. Symmetrical after pruning as well as pendent, it becomes one of our best weeping deciduous trees. But with nearly all trees and shrubs beauty of form and even colour depend greatly on intelligent pruning. Let me refer with due admiration to the fresh vigorous foliage of the Weeping Privet, which, like most of its relatives, it retains in full health until late in autumn.

The Moonseed.—Few realise the attractions of the Moonseed (*Menispermum canadense*), but why I cannot say. It is hardy and should be well known, for it is an old plant of excellent qualities. The way in which the vigorous, broad, heart-shaped leaves fold closely over each other is very curious as well as ornamental. It is, moreover, a very strong grower, easily propagated, and therefore cheap. It is, however, only another instance of a good old plant apparently doomed to neglect.

The Cut-leaved Sumach.—The changing colours of autumn again remind us of the peculiar attractions of the Cut-leaved Sumach (*Rhus glabra laciniata*). Many roadsides glow at this season with the common Sumach, but the same deep colour on the Cut-leaved variety is combined with the most delicate and lace-like divisions of the leaf. The very irregularity of the Sumach has such special charms that pruning fails to improve even the Cut-leaved variety, unless it be to curtail the dimensions of some overgrown specimen. All the Sumachs—*R. glabra laciniata*, as well as the beautiful new Chinese *R. Osbeckii*—belong on the outskirts or points of large shrub groups, where their peculiar form and colouring may be fully evident. Colour and irregular form alike make them prominent in such positions. If it is desirable to form them into masses—and it is often very desirable—they should be planted entirely by themselves on some hillside or slope. The way they are gathered together in their favourite haunts suggests the proper manner of arranging them. It is a mistake, however, to think that any soil will suit the different varieties of Sumach, simply because when wild they grow freely and abundantly. They like good loamy soil, and certainly, in all ways, deserve to have their likings considered, for as lawn plants in the autumn of the year few shrubs excel them.

Euonymus alatus.—This Japanese shrub has received its name *alatus* (or winged) from the peculiar ridges or wings that extend down the sides of the stem. These wings are sometimes enlarged to a striking degree, and are quite visible at some distance. The leaves resemble those of European *Euonymuses*, and also (more or less like European varieties) their autumnal colours are resplendent with red, deep orange, and yellow. Clusters of fruit, usually of marked character on the different *Euonymuses*, are small and almost insignificant on the *alatus*. A very distinctive peculiarity of this *Euonymus* may be noticed in the curve of its branches. They bend outward in a very decided and graceful manner. This habit is so distinct that it is the first peculiarity noticed in this plant. *Euonymus alatus* is a new variety, at least to the public. Lavallée describes it in the catalogue of his arboretum, and ascribes its early botanical description to Thunberg. Indeed, he gives E. Thunbergi as one of its synonyms. The *Euonymus* family is so attractive in all its forms that another distinct species or variety possesses a peculiar value. We are sure if lawn planters would mass all the varieties together in a single group on the lawn, their effect upon every one would be alike novel and charming.—*Country Gentleman*.

CORAL SEA-SHORE VEGETATION.

ONLY a few in cold climates have any idea of the great beauty of a coral reef as seen in tropical seas from a boat on a fine day, when the sea is calm. The different objects seen through the clear water are so numerous and varied, their forms so beautiful and wonderful, and their colours so bright and pleasing, that it is impossible to portray them in a manner which would convey a just idea of their grandeur and loveliness. Even the accompanying illustration—good though it be—falls immeasurably short of the reality. But it is not the sea to which I am desirous of calling attention; it is the land forming these far-away shores and the plants growing thereon. How delightful is a walk on these shores, over the white sand, shaded from the fiercely hot tropical sun by such trees as *Barringtonia speciosa*, *Hernandia peltata*, *Calophyllum luophyllum*, *Pongamia glabra*, *Cordia*

subcordata, Ochrosia parviflora, Terminalia Catappa, Pandanus odoratissimus, Cocoa-nut Palms, &c., and such shrubs as Scaevola Koenigi, Tournefortia argentea, Cerbera Odollum, &c., creepers and climbers innumerable, all growing higgledy-piggledy, the one on the top of the other. On the swampy parts of these shores grows the curious Mangrove, sending out numerous adventitious roots from its branches, and gradually advancing on the sea, on stilts as it were, and, by entangling mud, &c., among its roots, reclaiming land from the stormy waters. The seeds of the Mangrove do not lie down when on a voyage, they swim upright, and so, when they touch the shore, they are in the best position to take advantage of this circumstance, and if the shore be favourable (*i.e.*, soft and muddy) there they remain. Each inflowing and outgoing wave shakes the seeds to and fro, and the more they are shaken the deeper and firmer do they sink into the mud, until only about 3 in. of them remain above it. Then the water does not disturb them, and they emit roots and grow. These salt-water marshes are the abode of the *Acrostichum aureum*, of the scarlet-flowering *Lumnitzera coccinea*, the "Looking-glass Tree" (*Heritiera littoralis*), whose seeds are shaped like the bottom of a boat, including the keel. Several species of *Mucuna*, *Derris*, and other climbers, grow on the borders of these swamps. They scramble over the tops of the Mangrove, binding the branches together in a tangled mass.

But to return to the coralline beach. The *Calophyllum Inophyllum* (Tacamahaca—Takamaka) is not a lofty-growing tree, but it has a wide-spreading head of dark, bright green leaves, which glitter in the sunshine. Its limbs are large, and its foliage gives shade to numbers of epiphytes which grow on the tree. Among them may be seen several kinds of gay flowering Orchids (*Dendrobium* &c.) growing within reach of the salt spray; also such Ferns as *Neottopteris Nidus*, with fronds as large as the leaves of a Banana, various *Asplenium* and *Davallias*, having finely and delicately-divided fronds. *Lycopodiums*, such as *L. Phlegmaria*, *squarrosum*, *verticillatum*, &c., hang tassel-like from every branch, and creeping *Polypods* and climbing *Aroids* cover the trunk. The flowers of the *Takamaka*, which are as white as snow, are produced in great profusion, and contrast finely with the dark green leaves. Those of the *Barringtonia* are about 3 in. or 4 in. in diameter, and have large rose-coloured petals and stamens; this tree is well known as a fine-foliaged plant in hothouses, where it seldom flowers. Its four-angled seeds are used as floats for fishing nets, and, from their resembling the square caps worn by priests, they are called *Bonnet carré* or *Bonnet de Prêtre* by the French. *Guettarda speciosa* bears white flowers whose fragrance perfumes the air. With the seeds of the *Cordia subcordata*, a handsome tree which grows to the size of a Plane, the natives of the islands in the Coral Seas make necklaces. They use its bright yellow flowers strung—*faute de mieux*—on a piece of tough climber for wreaths, &c. For the same purpose they use the gay flowers—especially sweet-smelling ones—of many other plants, and make crowns and coronets with fronds of Ferns, particularly those of *Lygodium* and *Lycopods*. The leaves of the *Terminalia* change from green to a reddish colour before they fall, and add a variety of tints to the scenery. The flowers of the *Pongamia* are blue, those of the *Ochrosia* white, with a red spot at the mouth of the corolla tube. *Hernandia* is a well-known hothouse plant, the flowers of which are seldom seen in this cold country; but, as their beauty is not great, there is not much on that account to regret. But without them there would be no fruit, and the fruit of the *Hernandia* is in some respects a curiosity. After flowering, the involucre swells to the size of a turkey's egg, leaving an aperture $\frac{1}{2}$ in. wide at its apex. The seed hangs inside the bladder-looking involucre like the clapper of a bell. The deeply-lobed leaves of the Bread-fruit tree, and those of the Cocoa-nut Palm and *Pandanus* give change of outline.

Coral Bottomed Lagoon.

The home of the Cocoa-nut tree is the coral islands of the Pacific Ocean, but no one knows the island from which it emigrated. It has now made itself a home on the shores of all tropical countries, but it does not thrive well beyond 18° or 19° of latitude north or south of the Equator. From Pointe de Galle to Colombo, in Ceylon, the road for seventy-two miles is through an enormous grove of Cocoa-nut and Bread-fruit trees. There, as in many other places, it is all and all to the inhabitants. In favourite abodes it often grows to a height of 80 ft., and probably reaches a hundred years of age, bearing large crops of nuts annually for about eighty-five or ninety years, averaging one hundred nuts per tree per annum during that long time. Cocoa-nut milk—the watery fluid contained in the green nut—is an excellent cooling and refreshing drink; in cool mornings it sparkles and fizzes not unlike soda water.

Towering above the Cocoa-nut trees, or mingling with their leaves, are the boughs of the *Terminalia Catappa*, the country Almond of India, so called from the resemblance which the taste of its seeds have to that of the last-mentioned fruit. The natives like this Almond tree, and plant it near their dwellings; its foliage affords them shade from the noon-day sun, and its nuts food. From the kernels of these they also make bread. High above all the other trees that grow on the shores of these islands, which may be said to own their existence above mother ocean to the work of countless insects, the *Casuarina equisetifolia*, "Filao" or "Vilao," raises its spire-shaped head to the height of one hundred and eighty feet from the ground. Its leaves and branches moan when moved by the breeze as if weary of existence; truly their sound is weird and dreary. But here is *Ipomœa pes-capræ* creeping over the coral sand, which it covers with a green carpet; its flowers are large, bright purple coloured, and truly handsome. It is seldom seen in hothouses, even in botanical collections of plants. It thrives best in soil in which there is a good deal of lime or saline matter. With plenty of moisture within reach of its roots, it would grow admirably among lime rubbish pure and simple, finely sifted, or a half-and-half mixture of lime rubbish and leaf-mould would suit it perfectly. J. H.

The Phylloxera.—The report of Mr. Vice-Consul Hayes Sadler on the trade of La Rochelle contains some interesting facts. The French districts attacked by the *Phylloxera* may be divided into two great blocks, the one embracing the valley of the Rhone, the neighbouring departments, and the shores of the Mediterranean, where the *Phylloxera* first appeared; the other, in the west, including the departments, or portions of the departments, of Charente, Charente Inférieure, Gironde, Lot et Garonne, Lot, Corrèze, Dordogne, Deux Sèvres, and Vienne. It is worthy of remark that those arrondissements are most completely devastated where the introduction of foreign Vines or those from other infected places was permitted. The brandy districts of Saintes and St. Jean d'Angely, and, indeed, the whole brandy district of the Charente, as well as the departments of Var, Gard, and Bouches du Rhône, are scarcely able to furnish sufficient brandy for local consumption; and, as no fresh plantations of Vines are being made, the whole character of the country will shortly be changed. The *Phylloxera* is not the only scourge that has been playing havoc with the Vines, for the *pyrale* (*Pyrallis vitana*), a most destructive caterpillar, has been doing great damage to the buds and young leaves, and is increasing greatly. The *gribouri*, or *escrivain* (*Eumolpus vitis*), a beetle with reddish brown wings, has also been killing the roots in some departments.

Mice *v.* Grapes.—All who grow Grapes under glass may not know that if mice get access to the house they attack and destroy the finest fruit. I saw the havoc that was being wrought among the bunches, but as I had taken the precaution to have the ventilators left a little open at night to prevent mildew, I placed the mice

chief done to the account of the sparrows and finches, for of these we have any number about the place. However, the other day I discovered my error. The Vinery, having frames and lights in front to cover the roots, the mice had burrowed down, got into them, and therein made a home. The aperture in the brickwork for the admission of the stems into the house served as doorways for them, and to my mortification pretty good use they have made of them.—M.

ANSWERS TO CORRESPONDENTS.

Green Fly on Chrysanthemums.—I have some very fine Chrysanthemums which are coming into flower; they are very much covered with green fly. Would smoking them with Tobacco do them any harm? or do you know what is the best thing to kill the fly?—SUBSCRIBER. [Smoking with Tobacco will kill the green fly and not injure the Chrysanthemums.]

Bouquet Dahlias.—Kindly furnish me with the names of the best twelve of these.—YORKSHIRE. [The following may possibly answer your purpose, viz., Amorette, pale yellow; Clemetine, delicate pink; Dr. Webb, rich scarlet; Flambeau, bright crimson; Little Beauty, pure white; Little Dear, bluish, tipped rose; Little Lydia, golden yellow; Little Nigger or Raphael, dark crimson; Little Snowball, pure white; Little Willie, flesh; Peasant Girl, white, with a carmine centre; Sacramento, yellow, tipped with scarlet. Now is the best time to get them, as you make sure of obtaining good roots. In spring cuttings recently struck are often substituted.—J. O'B.]

Rhododendrons.—What are the best hardy Rhododendrons for planting in clumps? This (Stow-on-the-Wold) is a very exposed situation, so the varieties should be quite hardy.—T. W. S. [The following are thoroughly good and perfectly hardy, viz., Blandyanum, scarlet; Kate Waterer, rose; John Waterer, scarlet; Lady Cathcart, rose; B. W. Currie and the Warrior, scarlet; Everestianum, lilac; Gloriosum, the Queen, Madame Corballo, and Perspicum, white; Nero, purple; Mrs. John Waterer and Lord Palmerston, rose; Robert Waterer, scarlet; Mrs. John Penn and James Mason, rose; John Walter and Helen Waterer, scarlet; Duchess of Edinburgh, rose; Joseph Whitworth, dark purple; Crown Prince, rose; Alexander Adie, scarlet; Album, Triumphans, white.—J. WATERER, *Bagshot*.]

Grapes Cracking.—My Grapes, I see, are beginning to crack. How can I prevent such a mishap?—BETA. [Where cracking takes place in a well-ventilated house, the cause is, in all probability, a wet border. Some kinds, such as Madresfield Court, are more liable to crack than others, and require careful management when ripening. Where cracking is apprehended cover the border outside with a waterproof covering to throw off heavy rains. If this does not have the desired effect, cut a notch in the branches carrying the bunches, just below the bunch, nearly half through the branch. In all cases where the Grapes are ripening the ventilation should be ample both night and day; and those kinds of Grapes liable to crack should have their roots confined to inside borders.—E.]

Converting Bones into Manure.—Is there any way by which I can reduce bones to a powder so as to render them available for manure?—G. [Place the bones in an earthen vessel, and to every pound of bones add $\frac{1}{2}$ lb. of sulphuric acid, and the same quantity of water. Stir the mixture occasionally for three or four days. What results may be used in a liquid form or mixed with dry peat, charcoal dust, or some other absorbent, and used in a powdered condition. The sulphuric acid must be used with great care, as it destroys almost everything it touches, except glass or earthenware.—H.]

Passion-flower.—J. C. A. M.—Your flowerless Passion-flower is too well fed. Keep its roots out of the manure heap into which you state they have found their way, and it will probably produce blossoms.

Diseased Potatoes.—Q.—No one can tell much about a Potato in the condition sent. It looks as if it had suffered from a bad attack of Peronospora; but when the tuber is ruined like the specimen in question, the fungus has generally vanished for good. The fungus with its resting spores is never found in a dried-up tuber, but always in the very soft, juicy, and semi-transparent specimens.—W. G. S.

Camellias.—J. H.—They seem to be in good health; the variegation will do no harm.

Tropæolums.—G. F. D., *Copenhagen*.—Any of the leading Scotch or English nurserymen ought to be able to supply them.

Names of Plants.—M. S. D.—1, Adiantum trapeziforme; 2, Aspidium caryotoides. S. J.—1, Aster Novæ-Angliæ; 2, A. versicolor; 3, A. levis; 4, A. longifolius; 5, Oenothera riparia. W.—Nerine sarniensis. Surrey.—We cannot name from leaves only. M. T. S.—1, Pyrethrum uliginosum; 2, Rudbeckia hirta. Enquirer.—Apparently a species of Allamanda, but too much withered for recognition. G. H.—1, Ficus repens; 2, Croton pictum; 3, C. Wiesmanni; 4, A species of Oncidium, but it is difficult to say which from the material sent. Subscriber.—Next week. H. W.—1, Lasiandra macrantha; 2, Croton discolor; 3, C. ancubæfolium; 4, C. variegatum; 5, C. angustifolium; 6, apparently C. irregulare. G.—1, Aster versicolor; 2, A. Novæ-Angliæ var. pulchellus. May.—1, 2, & 3, Crested forms of Asplenium Filix-femina; 4, Asplenium bulbiferum; 5, Aspidium fulcatum. G. J. C.—1, Lobelia Erinus var.; 2, Campanula rotundifolia, probably, but cannot be certain without lower leaves. T. W. T.—Odontoglossum crispum (Alexandra), not rare.

Names of Fruits.—S. R.—Pears—1, Louise Bonne; 2, Gansel's Bergamot; 3, Marie Louise; 4, Beurré d'Arenberg. M. T.—1, Duchesse d'Angoulême; 2, Not in a condition to name; 3, Beurré d'Amanlis. J. S.—Apples—1, Nelson's Collin; 2, Hawthornden; 3, Peasgood's Nonesuch; 4, Winter Pearmain. Others next week.

THE GARDENING SEASON OF 1879.

THE whole of the horticultural press for the last six months has been keeping up one continual grumble, but for my own part I only see much to be thankful for. To notice the whole of the inmates of a fruit and vegetable garden would only be wasting time and space; but I may make a brief reference to the salient points. Taking what I may justly call the most useful of all fruits, viz., Gooseberries, Currants, Raspberries, and Strawberries, I must say

that I never saw more abundant crops. The only fault, if faults there were, was that they were all one month later in ripening than usual; but the quality of all was good. Let us next take Plums of all kinds, including Damsons. Of these I never saw better crops; we are just now supplying Victorias from a west wall for dessert, late Gages and Damsons for cooking purposes, and at this late period (Oct. 15) they are most acceptable and useful. Of Pears, we are now using Williams' Bon Chretien of good quality, but they lack the usual size; still little fishes are better than none. Passe Colmar, Ne Plus Meuris, Marie Louise, Thompson's, and that grand late Pear, Bergamotte d'Esperen, are all well cropped with good-sized fruit, which I feel confident will do us good service in due time. Of Peaches, I am still gathering Princess of Wales and Galande, only finishing the Royal George section a week back; while of Nectarines, both Pine-apple and Elruge are a good size and well coloured, and taking into consideration not the badness but the lateness of the season, of fairly good quality. Of Apples I have nine varieties which always crop well; only a few days back I gathered 5 bushels of Cackle Pippin off one tree, and a like quantity of another of what is locally called Cat's-head. Lord Suffield, King of the Pippins, Claygate Pearmain, Linden Pippin, Dutch Mignonne, Hawthornden, and Lady Lennox have all done well during the twelve years I have had charge of them; and to these I may add Peasgood's Nonesuch, the first year of its bearing here promising well. I may mention that Apples have not so bright an appearance as usual, nor are they so large, but still I see little ground for the grumbling to which we have been lately treated. Taking vegetables generally, and the king of them—viz., Potatoes—particularly, I have the same tale to tell. Our early crop (Myatt's) never was better; that is the chief kind which we grow in the garden proper. Our field crop consists of only four varieties, viz., Regents, Paterson's Victoria, Compton's Surprise, and Paterson's Champion. The average of the former is 36 bushels good and 6 diseased, while of the two latter, which, I am happy to say, are keeping well, there is not one in fifty diseased. Taking vegetables generally, I may safely assert that all have done fairly well. R. GILBERT.

OBITUARY.

MR. GEORGE GORDON, author of the "Pinetum," and one of the best known of the now old school of London horticulturists died on the 11th inst. He was one of the last of the "Chiswick School," and his mind was a mine of information on trees and shrubs as well as his special subject—Conifers. He was at one time a frequent contributor to THE GARDEN. His book on Conifers is considered the most useful one on the subject in this country, and it saw two editions, both published by Mr. H. G. Bohn. We believe some of his large collections of specimens went to the Kew herbarium and some to America. He was for many years superintendent of the arboretum department in the Royal Horticultural Gardens at Chiswick, where he had for companions in the other departments Munro, Thompson, and Fortune, the last now the only survivor. He was an Associate of the Linnean Society.

Nature announces the death of the well-known botanist, Mr. John Miers, F.R.S., F.L.S., which occurred on the 17th inst. Mr. Miers was born in London on August 25, 1789, of Yorkshire parents. After leaving school he devoted his time to the study of mineralogy and chemistry, but it was only subsequently, during his long residence in South America, that he acquired his taste for botanical knowledge, and by making dissections and drawings of plants he became a botanist. In 1825 he paid a short visit to England, and then published his "Travels in Chili and La Plata." He contributed many papers of interest to the Linnean Society, and published the "Illustrations" and "Contributions" to South American botany. His zeal and energy in his pursuits were most untiring, and he only desisted from his labours when forced by failing health in July last, since which time he gradually became weaker, till death ended his life on the 17th inst., in the ninety-first year of his age. It is understood that Mr. Miers has left his botanical collections to the British Museum.

We have received notices of the death of two of the founders of the Pomological Congress of France, viz., M. Baltet père, eighty years of age, founder of the nurseries of Croncels at Troyes, now conducted by his sons Charles and Ernest; and M. Willermory, founder of the Horticultural School at Ecully, near Lyons, now the Agricultural Institution of the Department of the Rhone, aged seventy-six.

The death is also announced of Dr. Eduard Fenzl, of Vienna, professor of botany, and director of the Imperial Botanical Cabinet. Dr. Fenzl was a member of the Vienna Academy of Sciences, and vice president of the Vienna Horticultural Society. He died on September 29 last at the age of seventy-two years.

"This is an art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare*.

NOTES OF THE WEEK.

Odontoglossum Londesboroughianum pardinum.—We have received from Messrs. Backhouse & Son, York, an example of this splendid variety. It is decidedly superior to any of the forms we have yet seen, as the flowers are not only larger—being upwards of 2 in. across—but the colours are more distinctly defined and brighter. The principal point of distinction, however, is the beautiful clear yellow lip, which is $1\frac{1}{2}$ in. broad, and copiously speckled all over the surface with reddish brown spots. Accompanying this were specimens of the lovely *Laelia albida bella*, with an amethyst tinted lip, and blush tinted sepals; the *atro-rubens* variety of *L. autumnalis*, a gorgeous form, with large flowers of a rich deep purple shaded crimson, and with the lip pure white in the upper half. Also flowers of *Cattleya maxima*, *Oncidium tigrinum*, the charming little *Barkeria Lindleyana*, Manle's *Cypripedium*, and an unusually fine form of *Odontoglossum maculatum*, with the colour very distinct and bright.

The Rattlesnake Plantain.—*Goodyera pubescens*, which bears the above English name in America, where it is wild in the woods of the Eastern States, is a beautiful little Orchid with leaves close to the ground, delicately veined with silver; it is, in fact, a hardy variegated Orchid, particularly distinct and pleasing, although its flowers are not showy. It has long been grown here and there in botanic and other choice collections, but never so successfully as it is now growing in Mr. G. F. Wilson's wild garden in Surrey. He planted it in a rich wood, exactly in the position in which it grows in its native home, and the plants look quite as well as we have ever seen them in America.

Angræcum Chailluanum.—This extremely rare Orchid may now be seen in flower in the Royal Exotic Nursery, Chelsea. In habit of growth it is similar to most of the other cultivated species. The flowers are produced on axillary racemes, and are much in the way of those of *A. sesquipedale*, though, of course, considerably smaller. They have the same waxy whiteness, and a spur upwards of 4 in. in length. It seems to be quite devoid of scent, rather a detracting point, as most of the other kinds possess that quality in a remarkable degree. It is a native of equatorial West Africa, and is named in compliment to Du Chaillu, the distinguished naturalist and African traveller.

Trafalgar Square.—We learn that the planting of this square with trees is in contemplation, and that Mr. Anthony Waterer, of the Knap Hill Nursery, Woking, has received instructions from the First Commissioner of Works to supply Plane trees for the purpose. The planting of a few trees in this locality has long been advocated in THE GARDEN. They are certainly much wanted in order to tone down, as it were, the huge piles of bricks and mortar which surround it.

Trichosma suavis.—Of this rare and extremely pretty Orchid, which is nearly allied to the *Erias*, there is now a fine show of bloom in one of Mr. Bull's Orchid houses at Chelsea. There are upwards of fifty racemes of flowers, and the aromatic perfume emitted by them is delicious, which well justifies the applicability of its specific name. The flowers resemble in form some of the smaller-flowered *Cœlogynes*, and are white with a golden-crested lip, the wing-like sides of which are beautifully marked with heavy pencillings of deep red on a pale ground. The stems are short, and bear a pair of smooth, shining leaves. In the same nursery there are many other highly interesting Orchids in full beauty, such as the pretty *Oncidium ornithorychium*, of which there is a large number, representing a great variety of shades of tint from pure white to the deepest rose. The singular *Dendrobium fimbriatum*, with its twisted flower segments, is still in bloom, as are also the Long-spurred *Dendrobe* (*D. longicornu*), a species with white flowers pencilled with orange streaks, the showy *Oncidium Rogersi*, and various others.

The May-flower (*Epigæa repens*) in an English Wood.—Mr. G. F. Wilson has this thriving perfectly in his wood, or wild garden. It is an extremely difficult plant to manage in nurseries and gardens, where one rarely sees it in a good state. We have seen it in New Jersey running about under the Fir trees and shrubs, and carpeting the woods, and we always felt that it only required a similar situation in this country to thrive well. It will

grow in any sandy wood where coarse or rank vegetation cannot exterminate it. This plant is called May-flower in New England, and Ground Laurel or Creeping *Arbutus* in other parts of the United States.

Cox's Orange Pippin from America.—There are some very fine fruits of this come from America, but when put to the eating test they are very disappointing, having lost their fine juice and become mealy and poor in flavour. Why this is so we cannot exactly say, but it is pretty clear that English Apples in America are not much better than American Apples in England, and that each country had better grow its own varieties. We have also tasted some Ribstons and Blenheim Oranges from America this year, which have the same failing, having lost their delicacy of flavour and become mealy. The great amount of sunlight and heat has probably carried them beyond the point at which they are best before they could be brought over.

Andromeda arborea.—This is called, and not inaptly, the Lily of the Valley Tree. It is certainly a beautiful tree, especially when seen in large specimens as that in Mr. Anthony Waterer's nursery at Knap Hill, where it has been for some considerable time an object of much beauty. The leaves are in size and shape like those of the Peach, but are white underneath, and have a pleasant acid taste, hence the origin of its popular name, the Sorrel Tree. The flowers are small, urn-shaped, of wax-like texture, and pure white, and are produced in profusion in terminal, forking, one-sided racemes, 6 in. to 8 in. long. It is a native of North America, where it grows plentifully in the valleys of the Alleghany Mountains, and often attains the height of 50 ft.

Mediterranean Reed Grass (*Arundo mauritanica*).—In the Water Lily house at Kew this very ornamental Grass has for some time past attracted much attention, on account of the graceful appearance of its huge feathery plumes, which are 2 ft. in length and from 8 in. to 10 in. in breadth, produced on stems nearly 12 ft. high. The handsome broad foliage, which is overlaid with a glaucous hue much increases its beauty. For growing in a warm greenhouse of sufficient size to admit of its full development, and where also it can obtain abundant moisture at the roots, there are few subjects more desirable. It is a singular fact that when planted in the open air in rather a dry soil, its leaves acquire an elegant variegation, but when placed again under liberal treatment the foliage reverts to its original character. Job's Tears (*Coix Laehryma*), and the White Rosseau (*Cyperium saccharoides*) are also very effective just now in the same house.

The Purple Swan Orchis (*Cycnoches Egertonianum purpureum*).—This is a remarkably singular Orchid, the flowers of which are very similar in form to that shown by Mr. Bull at the last meeting at South Kensington under the name of *C. Warszewiczi*. The colour of the flowers, however, is quite distinct, for, instead of being green, they are of a deep, velvety-maroon tint marbled with greenish streaks, which, combined with the graceful appearance of the racemes, renders it highly attractive and, from a horticultural standpoint, decidedly superior to the other kind. If large flowers are produced from the same bulb, as in the other, *C. Warszewiczi*, and of the same deep colour, it will be a desirable acquisition. It is now in perfection in Mr. Bull's nursery.

Pancreatum rotatum.—This is one of the most beautiful of the hardier species. It has flowers about 6 in. across, with narrow segments, and a shallow-fringed corona 2 in. in diameter, all of snowy whiteness, the only colour to mar their chaste beauty being their golden-tipped stamens. Their perfume is delicious—almost as powerful as that of some of the tropical kinds, such as *P. fragrans*. In its native habitat they have the peculiarity of only opening at night, or in cloudy weather. It is found on the marshy banks of streams in Kentucky, Virginia, and elsewhere in the more Southern States. We saw it a few days ago, beautifully in flower, in a cool house in Mr. Ware's nursery at Tottenham.

Orchids in Flower at Chelsea.—It may be interesting to Orchid lovers to know that the following are now in perfection at Messrs. Veitch & Sons' nursery. Of the splendid *Cattleya exoniensis* there is a grand example bearing many flowers, and a very fine form as regards well-defined richness of colour. The old *C. labiata*, of which the finest varieties appear to have become scarce, is here represented by some fine plants. A superb variety is bearing five flowers from one sheath, and of a size and depth of colour simply exquisite. Of *Cypripediums* there are the new *C. Spieerianum*, to which we alluded a short time since, *C. Arthurianum*, a handsome hybrid between *C. insigne* and *C. Fairreanum*, several forms of the pretty little *C. Schlimii*, and various others. *Cattleya Philbrickiana*, a beautiful hybrid, the result of a cross between *C. Aclandiae* and *C. Harrisoniae*, is still in flower, as is also the fine *Dendrobium formosum* and its variety *giganteum*, which for some time has been

a great ornament. There are few prettier sights at the present time than the several kinds of the Indian Crocus or Pleiones, of which there are several pans quite covered with flower. *P. lagenaria* and *P. maculata* are two well-known kinds, but none the less beautiful are *P. humilis*, *P. Walliebiana*, and its variety *præcox*. Of the more curious than showy Orchids, there are none in flower so remarkably singular as *Stelis Bruchmülleri*, a small growing kind with the habit of a *Masdevallia*. The racemes of flowers are produced from the sheathing leaf-stalks, and bear from twelve to sixteen tiny triangular-shaped flowers of a dull red hue, with the edges so beautifully fringed that they appear to be invested with wool.

Lilies in Woods.—Mr. G. F. Wilson has made a very interesting experiment on a large scale in the growth of Lilies in his wild garden in Surrey. In shade and partial shade of Oak and other native trees they have thriven well and flowered freely during the past season, when decay and disease were so rife among these plants that many despaired of their culture. Mr. Wilson believes, from his experience, that for many kinds the shade and shelter of trees and shrubs are desirable. It is also certain that in a wild state these plants often grow in woody places.—V.

Hydrangea paniculata grandiflora.—Some of the finest examples of this very handsome shrub with which we have yet met are in Mr. McIntosh's garden at Duneevan, Weybridge. They are growing amongst Rhododendrons, the green foliage of which forms a capital background for their huge clusters of white blossoms. Associated with them are also golden-rayed Lilies (*Lilium auratum*), which are well known to have here attained a size and luxuriance unsurpassed in this country. It is thus evident that the *Hydrangea* delights in a deep peaty soil, though it grows well in loamy soil, and a finer object in the autumn in any place could not well be imagined.

Ruta albiflora.—This very pretty Nepalese plant, which is also known as a species of *Bœninghausenia*, is one that is worthy of more attention as a decorative plant on account of its elegant habit and long, loose clusters of tiny, white, bell-shaped flowers. The foliage is somewhat similar to that of the common Rue, but it is more finely divided, more glaucous, and thinner in texture. As to its hardiness there appears to be some doubt, but probably it would withstand our ordinary winters in the open air. We saw it a few days ago finely in flower in Mr. G. F. Wilson's garden at Weybridge.

Aphelandra cristata.—The *Aphelandras* are all useful plants, but none are more valuable than this old-fashioned species, a grand specimen of which is now finely in flower in Mr. Bull's nursery. The brilliant scarlet flowers produced in such profusion in dense, erect clusters rising boldly above the foliage, render it a most desirable plant. Its protracted mode of flowering, too, is another and important recommendation, for it has been in full beauty for some considerable time. Like most of the other kinds it also flowers freely in a small state, if care is taken to select flowering shoots for the cuttings.

Maule's Japan Pear (*Pyrus Maulei*).—The handsome fruits of this shrub, of which a coloured figure was given in THE GARDEN (Vol. XIII., p. 390), are nearly as ornamental in autumn as the showy orange-scarlet blossoms are in spring. In Mr. Stevens' garden at Byfleet there are hedges of it, and just now its fruit is very attractive. The present season, however, has not been favourable for its growth, and therefore it is not nearly so large or so highly coloured as when the seasons are long and sunny. In the same garden various kinds of *Pyrus*, *Crataegus*, and *Cotoneaster* also present an ornamental appearance, owing to the numerous clusters of red fruits which they are now bearing. These and similar subjects are very desirable for associating with other kinds of shrubs, even for their autumn effect alone, and they are none the less prized for their beauty in spring.

The Phylloxera in Australia.—This dreadful scourge is not content with devastating the European Vineyards, but has appeared in those of Victoria, in the district of Geelong. The Bendigo Vignerons have sent a recommendation to the Government that the Geelong Vineyards should be at once purchased by the State and destroyed, and in this movement the New South Wales and South Australian Government have been asked to co-operate. The sum estimated for the purchase is about £30,000.

Jacquinia aurantiaca.—This pretty neat-growing shrub is now very attractive on the shelves in the Palm house at Kew. It has a compact, much branched habit, small deep green glossy leaves, and clusters of bright orange-red, bell-shaped blossoms about 1½ in. across. It is a native of South America, hence it requires a stove temperature.

Primroses.—Mr. Dean sends us flowers of hardy Primroses in several rich colours, to show not only the abundance of bloom that may now be found on many spring flowers, but also the rich beauty which these charming plants possess, and which seem to

grow more varied and attractive every year. Flowers of a new white double Daisy named Virginia also accompanied the Primroses. This is flowering freely now, whilst not a bloom is to be seen on other kinds. The stalks are long and the blooms so pure that it probably would pay grown under glass for button-hole bouquets.

A New Violet.—Mr. G. Lee has sent us from Clevedon flowers of a new Violet bearing the name of *Argenteaflora*. Its blossoms are large, pale purple, but in winter nearly white and deliciously fragrant. It is said to be very prolific, and almost a perpetual bloomer.

Autumn Flowering of Darwin's Barberry.—The large masses of this beautiful shrub in Mr. Hancock's garden at Oatlands Park, Weybridge, are in full flower at the present time, this being the second flowering this season; a point which much enhances the value of this fine hardy shrub. The past summer has apparently been favourable for its luxuriant growth, and, in most places, it has recovered from the effects of the last winter.

Appointments.—The following botanical appointments have been recently made by the Colonial Office:—H. Trimen, M.B., London, F.L.S., Senior Assistant in the Department of Botany, British Museum, to be Director of the Royal Botanic Garden, Ceylon, in the place of Dr. Thwaites, C.M.G., F.R.S., who retires on pension with the title of honorary Government Botanist.—Dr. Morris, B.A., Trinity College, Dublin, F.G.S., late Assistant Director of the Royal Botanic Garden, to be Director of the Botanical Department, Jamaica.—H. Marshall Ward, scholar of Christ's College, Cambridge, to be employed for two years as Cryptogamist in the investigation of the Coffee-leaf disease in Ceylon. He will be subordinated to the Director of the Botanic Garden, and will have the use of the Assistant Director's house. Mr. Morris and Mr. Ward were formerly students of the Science and Art Department.—*Nature*.

New Garden at St. Petersburg.—There are at present no gardens attached either to the Emperor of Russia's Winter Palace or to the Annitchkoff Palace of the Czarewitch, and the Emperor, whose regular habits of walking in St. Petersburg are well known, has hitherto been accustomed to take his daily constitutional in the summer garden on the Neva Quay or round about his palace. It is said therefore that the Czarewitch is anxious to provide a quiet retreat for the Emperor, where His Majesty may retire for relaxation from the cares of state instead of subjecting himself to all the inconveniences of public promenades. The garden proposed to be made by the Czarewitch will, therefore, no doubt be walled in and made strictly private as at Buckingham Palace, and the tall figure of the Emperor, no longer a young man and careworn with the burden of State, will henceforth be less familiar than hitherto among his subjects in the streets of St. Petersburg.

Marsh Fever.—Prof. Klebs, of Prague, and Prof. Tommasi, of Rome, have been examining during the past spring into the poison which produces marsh fever. The former has in a recent number of the *Zeitschrift*, given full particulars of the experiments made and the results obtained. These investigators examined the lower strata of the atmosphere of the Agro Romano and its soil. In both they discovered a microscopic fungus, consisting of movable shining spores of a long oval shape, about 9 micromillimètre in diameter. With these spores animals were artificially infected with intermittent fever of the true marsh type, and they showed precisely the same enlargement of the spleen as human beings who have caught the fever in the ordinary way. Messrs. Tommasi and Klebs have given this fungus the name of *Bacillus malarie*, as it grows into the shape of small reeds.

Woolly Aphis.—When repotting *Auriculas* I have sometimes found those added from other collections badly infested close to the sides of the pots with this pest; but when I came to those which I had had potted with the following compost for two seasons, there was not the slightest sign of an aphis. Formerly charcoal pits were fixed hereabouts—say ten or twelve years ago. I have obtained some of the refuse, which appears to be composed largely of charcoal and leaf-soil; also a little loam. After passing this through a fine riddle, it is used for the *Auriculas* without being further mixed, employing lumpy charcoal at the bottom instead of crocks. The result in this case being very satisfactory, may not this burnt refuse be an antidote for the aphis? I rarely find a worm in such compost.—JOHN WOOD, *Kirkstall*.

The Goat-moth is reported to be very destructive this year at Frodsham and thereabouts. The plantation from which Mr. Hibberd selected trees to illustrate his lecture on fruit culture at the Society of Arts a few years since was thinned to the extent of about twenty per cent. by this plague, the young trees being bored as by an auger, and death following soon after; therefore Frodsham has no monopoly of this plague.—*Gardener's Magazine*.

ROSES.

TEA ROSES FOR AUTUMN-FLOWERING.

WHEN chilling autumnal rains and nipping frosts have dimmed or destroyed the beauty of the flower garden, good flowers become scarce, and a serious deficiency in the supply is apt to occur. From this time forward, anything in the shape of a flower is welcome, and a single Rose-bud in the late autumn or early winter months is often of greater value to the grower than a whole bushful would be in the summer season. It is when choice flowers have become rare that a few good Tea Roses prove of immense service, and I consider that every establishment should make arrangements for extending the flowering season beyond the period at which plants usually cease blooming in the open air. The fragrance of Tea Roses is so delicious, and the colours so chaste and delicate, as to render them suitable for the choicest of floral decorations. With a half-expanded Rose-bud, a few sprays of Heath, Primula, and Maiden-hair Fern, a bouquet may be made capable of pleasing the most refined taste.

The plants intended for late-blooming are best grown in the open air, plunging the pots up to their rims, and either top-dressing with rotten manure or administering copious supplies of manure-water in hot weather. The object of the grower should be to encourage a free, hearty, luxuriant growth during the summer and early autumn months, thereby inducing the formation of healthy bushy heads of foliage, which by the middle of October will be studded with buds in various stages of development. By this time the plants should be placed under glass, leaving on full air night and day, merely closing up in frosty weather—treating them, in fact, like Chrysanthemums. A few plants thus grown will furnish blooms up to the middle of December, when they may be taken out and placed in a sheltered situation, covering them in severe weather, for the Tea Rose is always grateful for a little protection against hard frosts. In the spring shake away as much of the old soil as possible, and repot in good loam and rotten manure, and plunge the pots again in the open ground. Plants thus treated will yearly increase in vigour and bloom-bearing capacity, and will richly repay the grower for the pains which he may have expended upon their culture. Some kinds do not submit kindly to this treatment, but there are others which naturally flower so profusely at a late period of the year as to render the production of Roses at that time a comparatively easy matter.

Having quite recently gone through a large collection of Tea Roses growing in the open air, I have selected the following as best calculated to afford satisfaction when grown as already recommended, viz., Homère, rose, salmon centre, an old kind but one of the best, being vigorous and very floriferous; Perle des Jardins, yellow; Madame la Comtesse de Caserta; Madame Francois Janin; Souvenir d'un Ami, one of the very best kinds grown; Madame de St. Joseph; Madame Lambard, a very fine, large-flowered, in every way desirable variety; and Madame Falcot. These varieties were conspicuous amongst all others for the free manner in which, at such a late season of the

year, they were flowering, and would suffice, if well attended to, to prolong the flowering season into the winter months. Amongst other late-flowering kinds may be mentioned Aimée Vibert, Souvenir de la Malmaison, Antoine Verdier, Céline Forestier, and Solfaterre. I find, too, that amongst others I have omitted the glorious old Gloire de Dijon, one of the best of Teas; instead of finishing, I should have commenced with this fine kind. It may not be out of place to offer here a few words of advice to intending purchasers of Roses. I would counsel buyers to go themselves and see the plants growing, make their own selection, and have the trees taken up, and, if some time must elapse before reaching home, the roots should be enveloped in litter. Take the plants away with you, and damp the roots before laying them in the ground. Pot them as soon as possible, and if they cannot be sheltered in a deep pit or cold house, plunge the pots, and cover them in hard weather with bracken or litter of some kind. Tea Roses especially need all the care which can be expended on them, for unless they are well provided with roots in the spring they fail to make the amount of growth requisite for the production of good flowers in the autumn.

Byfleet. J. CORNHILL.

Climbing Rose on Old Tree at North End House, Twickenham.

Climbing Roses in the Wild Garden.—

One of the most charming effects in wild gardens may be obtained from the planting of some of the more vigorous climbing Roses in positions where they can take care of themselves. The pruning is so often injudiciously done that it is almost better to let them alone. In any case we have never seen climbing Roses so beautiful as when they are allowed to grow over some old tree or large shrub, and there tumble about in their own way. There is a good instance of this in Mr. Bohn's garden at Twickenham, where the Felicie Perpetuee had grown up an old Catalpa tree, and grown down again laden with showers of blossoms. A more picturesque object we have never seen. The accompanying illustration is an engraving from a drawing of it made for us by Mr. Alfred Parsons. Half-a-dozen free and bold varieties equally well trained would almost make a Rose garden of any place. Such things are indispensable in the wild garden

where that beautiful phase of gardening is understood.

Rose Duke of Teck.—Amongst the new Roses of the coming year, the Duke of Teck will take high rank. It is a true English Rose—a Cheshunt raised variety, and like all the seedlings produced there it possesses such a vigorous constitution as to be well suited to our English climate. The mode of raising seedling Roses may be expressed in a few words. The seeds are sown in open and perfectly unprotected beds, and by following out the principal of natural selection all the weakest plants are killed off the first winter, the strong, robust, hardy seedlings alone surviving. About the third year the seedlings bloom, and those of a promising character are worked, as Rose growers term it, that is if approved, one or two buds only being inserted. If again approved the variety is named and multiplied in quantity, and flowers are submitted for public approval at the various Rose exhibitions. This has been the course inspection by Messrs. Paul & Son, at the Old Cheshunt Nurseries, in respect of Duke of Teck, and it made its first appearance at the

exhibition of the Richmond Horticultural Society in June 1877, when it was much admired, and thought worthy of bearing the name of the president of the society; since then it has gained many honours, and among these a first-class certificate from the floral committee of the Royal Horticultural Society; the same at the Alexandra Palace Rose show, and it also gained Mr. G. P. Hawtreys prize for the best English seedling Rose not in commerce at the exhibition of the National Rose Society, and it has also received exceptional praise from all the horticultural journals. The conditions of Mr. Hawtreys prize required that the flowers be accompanied by a growing plant to show proof of vigour and a good constitution in the variety presented for the prize. In the case of Duke of Teck this proof was forthcoming and appeared to fully satisfy the judges. The colour of Duke of Teck is a bright crimson-scarlet, clear and distinct in its vividness beyond any existing variety; it makes a decided step towards the attainment of a true scarlet Rose. The flowers are large, very double, and of the best globular form, with splendid self-coloured petals. The habit of growth is more erect than that of its parent—the Duke of Edinburgh, and the general aspect more upright and vigorous. This Rose possesses an excellent quality: it is a true and good perpetual bloomer. The plants from which blooms were cut in June last were still bearing flowers so recently as October 24—plenty of good flowers and buds.—R. D.

THE FRUIT GARDEN.

THE EXTENSION SYSTEM OF PEACH TRAINING.

MR. COWBURN (p. 372) asks me what is meant by "extension" in regard to Peach tree training, and says that unless a tree is crippled through want of space or barbarous pruning it must naturally extend itself. My answer is that the extension system in garden practice means the confining of pruning operations simply to disbudding in spring, and such thinning out of the shoots during summer as may be found needful, and dispensing with winter pruning altogether as it is generally practised. The system can only be practised fully under glass in this country, or under circumstances in which the shoots get ripened to their extremities every season.

For correct instructions and illustrations on the "restrictive" or mutilation system, I could not refer Mr. Cowburn to a better or more recent authority than the last edition of the "Gardener's Assistant." It is to the instructions on fan training there given to which I refer. He will there see an illustration of a Peach tree cut down to one stump about 1 ft. high at the end of the first year; at the end of the second year to two stumps, about 6 in. long each; at the end of the third to four, and so on; giving a fruitless stunted tree at the end of several years, when it should have nearly filled a Peach house 20 ft. long and as much high, and borne quantities of fruit. More trees have been ruined by trying to follow advice such as is given in the work just alluded to than by any other means probably. The best that can be said about it is that no sensible cultivator tries to copy the abortions there delineated, nor did we ever hear of any one succeeding who tried. Figure 277, given at p. 450, is an impossibility consistent with fruitfulness. In our own case before giving the book to young gardeners to read we drew the pen through most of the illustrations on fan training, and we should recommend others to do the same before submitting an otherwise excellent work to any learner. No allusion is made to the extension system in the work so far as I have seen; but it will probably find a place in the next edition. The system, as the article in the *Gardener* by Mr. Coleman proves, has been in vogue a good while, and a few gardeners as well as myself have advocated it at times, and amongst others should be named Mr. Dick, of Phoenix Park, when he was at Canford Manor, Dorset. Some years ago I saw some fine trees there—young, but of large size for their age, and perfect examples as regarded health and fruitfulness.

Nor is the system applicable to the Peach only, but also to the Pear, Apple, Plum, and Cherry, and to many kinds of flowering and berried shrubs. I could at the present time show as fine examples of its effects on the fine old *Cratægus pyracantha* as could possibly be desired. These plants are quite young, and growing against a wall. Had they been pruned and pinched in the way generally practised with wall shrubs, they would have had no fruit upon them at their age, growing, as they are, in a strong rich soil; but they have been allowed to extend freely, laying in the leading shoots in all directions, and never shortening them back; and they are now complete masses of scarlet berries along their whole length, bearing out the theory that allowing the shoots to extend induces the production of fruit buds, while cutting back promotes wood growth chiefly. I apply the system also to Bougainvilleas and stove and greenhouse climbers generally. J. S. W.

FINE PEAR TREES.

I WILL take this opportunity of noticing two instances of remarkable Pear trees in this neighbourhood. Worlidge mentions "a Pear tree growing near Ross, in Herefordshire, in 1675, that was as wide in circumference as three men could encompass with their extended arms, and so large in the head that the fruit of it yielded seven hogsheads of perry in one year." The other is a still more remarkable tree. It grows in the vicarage garden and adjoining glebe land, in the parish of Holme Lacy, and has been celebrated for upwards of a century for its peculiarity of growth and its abundance of fruit. In the Parish Register of Holme Lacy for the year 1776 is the following entry:—

"Mem.—It is likewise inserted as a great natural curiosity, that the great Pear tree upon the glebe adjoining to the vicarage house produced this year fourteen hogsheads of perry, each hogshead containing 100 gallons."

Since this time, tradition states that it has yielded fifteen, sixteen, and, upon one occasion, as much as twenty hogsheads of perry in a single season. It has been well described by Duncumb in his "Agriculture" (1813) in these terms:—

"An extraordinary (Pear) tree, growing on the glebe land of the parish of Holme-Lacey, has more than once filled fifteen hogsheads in the same way. When the branches of this tree in its original state became long and heavy, their extreme ends necessarily fell to the ground, and taking fresh root at the several points where they touched it, each branch became a new tree, and in its turn produced others in the same way. Nearly half an acre of land remains covered at the present time. Some of the branches have fallen over the hedge into an adjacent meadow, and little difficulty would be found in extending its progress." (P. 90).

The tree is very curious and interesting at the present time. In the vicarage garden the group of stems is very picturesque, and several of the trees rise to a height of from 30 ft. to 40 ft. There are still nine stems on the lawn, one in the hedge, and seven in the adjoining meadow. Some creeping prostrate stems and a few upright ones have been removed for lawn improvement. The fruit trees in the garden have a circumference of from 7 ft. to 9 ft. 6 in. in the bole; and, added together, the trees give a total circumference of no less than 94 ft. In another meadow at a little distance is a complete grove of the same kind of Pear trees. They all seem to have sprung from one original tree, creeping along the ground in the same way as those in the garden have done. Its trunk lies prostrate and perishing whenever a new tree is not springing from it. The trees grow closely together, and form a cluster nearly 44 yards in diameter. This group grows upon land which formed part of the glebe until the year 1875, when it was exchanged for other land belonging to the domain, more convenient for the vicarage.—H. SCUDAMORE STANHOPE, in "Herefordshire Pomona."

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Grapes and Strawberries at Wortley.—The Grapes at Wortley are all that could possibly be desired, especially Black Hamburgs, which are particularly good. One of the houses that had not been cut at the time of my visit was about 50 ft. in length, and the Vines in it were planted about 2 ft. apart. The rods are about 19 ft. in length, and each bears on an average at least 30 lb. of fruit, and one could not find a badly finished bunch in the whole house. These Vines have been planted twenty-five years, and each year they have carried equally heavy crops. The foliage was healthy, and the wood well-ripened in all the Vineries, and thus, notwithstanding the inclement season, promise well for another year. As regards Strawberries, the bulk of those for forcing appeared to be Black Prince and Vicomtesse Héricart de Thury, all in smaller pots than one usually sees them in, viz., 5½-in. ones for the last-named kind, and smaller ones for the Black Prince. All of them had large well-ripened crowns, and the pots were filled with a mass of healthy roots. In short, they might be thrown to any distance without disturbing the ball. One rarely sees such fine plants of Black Prince for forcing, and, judging from present appearances, they will doubtless produce good fruits.—G. SUMMERS, *Sandbeck Park*.

Chasselas de Fontainebleau.—One day in the summer of 1599, Henri IV., visiting the park of Fontainebleau, complained to the gardener that there were few flowers. The latter replied that he could grow nothing on the ground. "Sow Gascons, then," said the King, looking at the Duke d'Epemon, who was by his side, "they thrive everywhere!" "The Vine of Bearn, whose juice gives spirit to the Gascons, would do still better," replied d'Epemon. "That is an idea," said the King, who ordered his gardener to plant some stocks from Jurançon. The instructions were obeyed, and the Vine succeeded admirably. The long walls to the north of the park are

covered with trellis called "Treille du Roi," on which are produced immense quantities of the Grape called *chasselas*. The produce of this terrace was reserved exclusively for the tables of the Sovereigns Henri IV., Louis XIII., Louis XIV., and Louis XV., who throughout the year had Fontainebleau *chasselas* served up at dessert. However, the ministers, nobles, and favourites received baskets of Grapes from the park at the time of the vintage. During more than a century this trellis was the only place in the neighbourhood which produced good Grapes. But in 1730 a cultivator of Thomery obtained some cuttings which succeeded perfectly, and he speedily had imitators. Soon the whole neighbourhood was occupied in the cultivation of the Vine. Paris alone consumes more than 220,000 kilos. of *chasselas* annually, and what is very singular is that this excellent fruit does not owe its quality either to the position or nature of the ground. Thomery is not favourably situated, and its soil has few of the conditions essential to the Grape. The superiority is due to the choice of the Vines, and to the care taken in their cultivation. Curiously enough, this delicious fruit is totally unsuited

THE INDOOR GARDEN.

PICTURESQUE GREENHOUSES.

It is greatly to be desired that greenhouses were really green, instead of presenting a dismal picture of red pots and stages of insignificant plants. It is rare, indeed, in England to see a conservatory (which is only a fine word for a greenhouse) laid out in anything like a graceful manner; and yet nothing is easier. The trouble and time required in putting all the little plants in pots for a moderate-sized greenhouse, and the constant watering would, applied on what we conceive the true system, produce a much better effect in a house three times the size. The only true way is to treat a conservatory—that is to say a large greenhouse—like a small open-air garden, and to make it as free from all objectionable matters or surfaces as we would like a very pretty little garden to be. Of course we must draw a line between the greenhouse or conservatory or what is called a plant house,

A Green Greenhouse

for making wine. The word *chasselas* is the name of a village in the Saône-et-Loire, not far from Mâcon. In that district *chasselas* is an expression used to designate a Grape of fine flavour.

Bags Best for Fruit Gathering.—In place of these (p. 372) I much prefer a good large apron with a stout string or cord round the waist, formed into a satchel by bringing one of the lower corners through the string, meeting it with the other, and tying them together in a firm knot. In this way both hands are at liberty, and by untying the knot the contents are more easily emptied than they would be out of a bag. This, of course, likewise applies to small vegetables, such as Peas, Beans, &c., where two hands are also necessary.—T. COWBURN, *Sunbury Park*.

Green Yair Pear.—This old Scotch Pear is one of the few that have fairly come to maturity in the Cleveland district of Yorkshire this season. The crop, too, has been good, and the fruit has been selling at about double the price of that of the Hesse Pear. Any Pear that has stood the test of this season is worth notice. The Hesse or Hazel is a standard market Pear, which in ordinary seasons bears an abundant crop, but in size and quality the fruit is inferior, and its market rate low.—CHAS. McDONALD.

because the plant house must be always adapted to the growth of a plant, whereas the greenhouse, or what answers for it, is supposed to be a home containing the choicest flowering plants during the very best season of their bloom. The simple remedy in this case is to plant out the cool house, instead of adorning it with stages in the usual way. There are now a great many beautiful and graceful plants in the country from sub-tropical and temperate climes that grow most freely planted out in a cool or temperate house. A beautiful house could be made with these alone, without the addition of the ordinary greenhouse favourites; but the height of beauty is attained by adding a few flowering greenhouse plants amongst those planted out permanently in the structure. A little bed of Chinese Primroses, a handsome "cool" Orchid, a graceful tall Fuchsia, a beautiful Azalea in flower—these, and such as these, brought in fresh, enhance the charm of the general effect. In old times the planting out of the greenhouse was not so uncommon as it is now, but generally subjects were chosen, such as Acacias, &c., which quickly ran up to the roof and became ragged and unclean. The right kinds are such plants as the New Zealand Flax, the hardier Palms, and greenhouse Palms, the Bamboos, large Ferns, &c., and also many others, such as *Dracenas*. We notice a *Philodendron* and *Strelitzia* doing

very well in the cool house in the Regent's Park. The large Tree Ferns of Australia would do beautifully, and there are some flowering plants which would also grow well with these, such as the white *Brugmansia*, and a variety of beautiful pillar and roof plants. The bed of the conservatory must, of course, be designed with reference to planting out, and have only as much walk as is necessary, and that, as a rule, towards the outer side. Our illustration shows a very beautiful conservatory of this sort, one formed by Madame Fould at St. Germain. Here and there in this house there are little beds in the turf for the reception of flowering plants, which are planted in masses; Orchids and larger subjects are placed between the fine-foliaged plants, so that little or no pot is seen anywhere in the house, but throughout a charming miniature landscape of graceful forms and bright blossoms, with a pretty little lawn of Moss in the middle.

UNTRAINED STOVE AND GREENHOUSE SHRUBS.

It is a pleasing sign of the times that formally-trained specimen plants are beginning to fall into disrepute. The most that is claimed for such now, even by those who encouraged formal methods of training most, by precept and example, is that they are convenient for exhibition purposes. In private gardens it is not contended that formal training is at all necessary. If nothing were gained but the time, this would be a matter of congratulation. Proprietors of gardens have hardly any idea of the cost of training a lot of specimen plants when "specimen" growing is carried out anything like fully. We have known many gardens where even important duties were neglected in order to attend to the few specimen plants on the place, which nobody saw, and in which the proprietor had hardly any pleasure or interest, all being destined for show purposes. When these were fulfilled, the routine of preparing the plants for another campaign began again; and so it went on year after year. We do not wish to disparage exhibitions, of course, but we apprehend their true purpose is not to encourage the mere business of specimen growing and nothing else. There are cases where the subjects exhibited represent the state of the garden from which they come, and reflect the skill and management generally, but they are few. These facts many gentlemen are well aware of, and hence they decline to allow their gardeners to exhibit plants. It is different in the case of fruit. A gardener cannot possibly continue to exhibit good Grapes year after year, and at numerous shows during the season, unless he has good crops generally; and it is but a fractional portion, after all, that is shown, so that the home supply is hardly infringed upon. And it is the same with Pines, Peaches, and other fruits. We are acquainted with gardeners who are amongst the foremost exhibitors of Pine-apples, and yet, in addition to supplying their employers' tables, dispose of perhaps £100 worth per annum in Covent Garden, where their fruit has been well known for years back.

Coming more directly to the subject of training plants, it will suffice perhaps to give a few general hints upon some of the most popular subjects. The Azalea is perhaps the plant that has been operated upon most commonly by the trainer; we do not remember ever to have seen a naturally grown specimen set up for competition on any notable occasion, but pyramids—most of them very one-sided—bell, and umbrella-shaped specimens have always been common enough. Now the Azalea, and also the greenhouse *Rhododendrons*, are most accommodating subjects if left to themselves, in which condition, too, they are more easily preserved in health. The young plants which can be procured cheaply at the nursery, with stems 12 in. or 15 in. high, make the best plants for house furnishing or for the conservatory, and also for entering form, and they will stand the latter operation, too, without disfigurement, which a symmetrically trained specimen will not do. If the plants be liberally treated, and not over-potted, they will naturally develop rather round or broad heads, just according to the habit of the variety, and will never need touching with the knife, or a single tie or stake of any kind. To attempt to convert such plants into formal specimens is to render them useless for the first few years. Small as they are, they are effective and useful when allowed to grow naturally, but any tying down reduces the size and makes them abortions for the time. They can also be preserved of any size and confined to small pots as long as desirable, by reducing the heads with the knife occasionally, and reducing the roots at potting time. We have numbers of plants of various sizes that have been confined to small pots suitable for Roses for years, without in the least interfering with their health.

The same remarks apply, as a rule, also to such subjects as *Acacias*, *Genistas*, *Boronias*, *Daphnes*, *Neriums*, and indeed all the shrubby and erect-habited greenhouse plants. With some close young species, which it might be desirable to have good-sized plants of, or when it is necessary to open up the branches to admit light and air to the foliage, a certain amount of staking is, of course, allowable and necessary; but it should be so managed as

not to offend the eye. Nor need there be any hard and fast line drawn as to the matter of shape and symmetry. A bare-limbed, ill-furnished, and straggling subject, created by neglect or bad culture, nobody likes to see, and it is right to make shapely plants of such by the readiest means, whether by the use of stakes or ties; nor is there any objection even to a certain evenness of outline, particularly in the case of plants that naturally grow that way; but attempting to imitate a pyramid, an obelisk, a balloon, or any other purely artificial figure is as little desirable as attempting to make similar objects of the ornamental trees and shrubs in our parks and pleasure-grounds—a practice which no landscape gardener of the present day would dare to advocate or encourage.

Of all hard-wooded plants which have been operated upon by the plant-grower, probably the Cape Heaths have been tortured the most. In their case training has been carried to such a length as, in some instances, to completely disfigure the plants. It used to be quite a common occurrence to see Heaths in noted collections at the great shows in which all the flowers had been bent or tied this way and that so late as the day before the show apparently, in order that the whole surface of the round, stiff, and formal-shaped head might be covered in perfectly regular fashion all over, utterly regardless of the plant's natural habit. We have often seen Heaths of the tricolor class trained in this unnatural way, and not only have they been passed without protest by those who are considered competent judges, but awarded valuable prizes, and afterwards described as "models of successful culture." A plant of *Erica Aitoniana*, *Turnbulli*, *Austiniana*, or *Marnockiana*, is a pretty object when well formed, and when all their flowers stand naturally erect; but when laid down so as to show the wrong side of the flowers and the foliage, and so as to produce an even-surfaced specimen, they are pitiable objects. Many of the finer soft-wooded Heaths, such as *hyemalis*, and others of the *ventricosa* and *colorans* type want no training whatever, but both grow and look better by being left alone, except being pruned or cut well back when done flowering. The hard-wooded close-growing section do need a little assistance from stakes, both to open them out and prevent the more straggly kinds from falling over the sides of the pots and getting into confusion, but a forest of sticks is not required to do this. We have seen such plants at exhibitions with so many stakes in them that their points could hardly find room on the surface of the pot. Such specimens are more like potfuls of stakes than plants. The hard-wooded kinds are seldom cultivated except in collections of Heaths. They are not generally useful to any one for affording cut flowers or for decorative purposes; hence we find that those who grow for the market confine themselves almost exclusively to the soft-wooded kinds, such as those before mentioned, and to which may be added the yellow *Erica Cavendishi gracilis*. All the erect-plumed varieties are handsome, and none of the hard-wooded tricolor kinds surpass the *ventricosas*, of which there are several varieties easily cultivated. It is a matter of little consequence whether they be supported by stakes or not, as by liberal treatment and clipping the flowering shoots back annually they can be retained in almost any shape desired.

What applies to greenhouse plants applies also to the shrubby stove species. We advise nothing to be neglected in the way of either training or staking that is likely to promote the health of the subject; but twisting the shoots in the most unnatural ways for the sake of bringing the plant into some fanciful shape, is neither demanded by good taste nor by the necessities of culture. A houseful of formally-trained specimens is not a pleasing sight, and we do not suppose such specimen-growers have ever yet entered a competition where an artistic arrangement was the object.

We cannot help thinking that the encouragement given to formally-trained plants, to the exclusion of more naturally-grown subjects in the same classes, has been more due to judges than to horticultural societies. It has been well understood among plant growers that there was no hope of success for anyone who entered the lists unless he conformed to the system of training encouraged—no matter how good his plants may have been otherwise. For example, a person might exhibit a large and well-flowered and naturally-grown *Pelargonium*, but it would have no chance against the pancake-shaped specimen, though it might be equal to the latter, or perhaps better, as a healthy, well-flowered plant; and it is just the same with stove or greenhouse plants. Were it only known that informally-trained plants would be encouraged and have a chance of success, exhibitors would be more numerous than they have ever been yet, and the prizes would not be distributed year after year amongst about a dozen of the same exhibitors.—*Fitch*.

Pachystoma Thompsoni.—The annexed engraving represents a remarkably handsome new *Orchid* which was exhibited by Messrs. Veitch at the last meeting at South Kensington, when it was

awarded a first-class certificate. The genus *Pachystoma* is a small one consisting of about eight species only, all of which are of Asiatic origin. They are very varied as regards habit, some having knotted and others fibrous roots. The plant illustrated resembles some of the *Bletias* in habit, and has flowers 3 in. across of waxy whiteness; the singular hooked lip is of a beautiful clear magenta hue with white grooves on the upper surface, the wing-like appendages are pale green, copiously freckled on the inner faces with brown; the column is also of the same colour. It is a native of West Tropical Africa, from whence it has been introduced by Messrs. Veitch & Sons, Chelsea, from a plant in whose nursery our woodcut was prepared.—W. G.

POTTING AND PLANTING BULBS.

To defer the potting or planting of bulbs to the late period at which that operation is generally done is a great mistake, as every day they are kept out of the ground is so much loss. Instead of forming fresh roots in the gradual way they would do, they are losing the juices stored up at the time when the tops ripened; and if a comparison of bulbs kept on dry shelves and in paper bags, and others left in the ground to come on in their own natural way, were made, the difference in favour of the latter would be most striking. This has been brought before me very forcibly this season with some *Gladioli*, which, owing to alterations being made in a border, were not planted till late. Near these were others that had been left in the ground all winter, the latter of which bore magnificent spikes, while many of the former did not flower at all, and the few that did so were not half the size or height of those that had not been disturbed, although, as regards depth of soil, and other circumstances everything was in their favour. There is an opinion among many that the corms of *Gladioli* are not sufficiently hardy to stand out during the winter; but that depends on the depth at which they have been planted, and whether the bed or border they may happen to be in is properly drained, or the ground in other respects suitable. To grow these beautiful flowers really well, trenching is one of the main things to be attended to, as a deep stirring of the soil such as this gives allows the water from heavy rainfalls to drain away instead of laying about them in a stagnant state, a condition that is sure to prove fatal to almost any bulbs or tubers.

The way in which we manage here in preparing for all plants of this class is to take out a good opening, and in turning over the earth to see that the top spit is laid in that position again, as to bring the bottom to the surface in its crude state takes years to get it in that condition in which roots will feed on it freely. What manure, however, is given is worked in below, so as to keep it from

coming in contact with the bulbs, none of which like it in close proximity to them, although all are greatly benefited by having it within reach of their feeders, and these appear to have a sort of instinct in finding it out, for they will travel a long way in search of it. Where leaf-mould or peat can be had in quantity they should be used without stint, as they not only assist materially in keeping the soil open, but all plants of a bulbous or tuberous-rooted description are fond of both, and for Lilies, peat suits better than anything else. These, therefore, do remarkably well in *Rhododendron* beds, or near the margin of these shrubs, the branches of which form just the natural shade they require; for although the upper portion of the Lily stems and flowers will bear and enjoy a fair share of the sun's rays, the lower part and the collar of the plant will not, especially those kinds such as *L. auratum* and others that form roots for their support just above the top of the bulbs. In growing these, therefore, this should not be lost sight of, for if they are not

well attended to with water and mulched during the summer season, when at all exposed to drying influences, much disappointment is sure to be the result. I am of opinion that thousands of bulbs of these beautiful plants are lost annually from a want of knowledge of their proper treatment in these respects, or long ere this they would be much more plentiful than they now are, seeing the large importations that have been made yearly, and that they are still sent over in greater quantities than ever. As their time of arrival is now at hand, I would recommend all who think of growing them, either in pots, beds, or borders, not to delay getting what they require, for, as already observed, every day now is an object, and the longer they are kept out of the ground the weaker will they be.

In planting any of the Lilies they should not be put in at less depth than from 4 in. to 6 in., at least all such as are strong growers; and of whatever kind they are, or whatever the soil may be in which they are to be planted, it is highly important that they have a handful or

two of clean, sharp sand placed around them, which answers the two-fold purpose of preserving the bulbs from excess of damp during the winter, and keeping them in a healthy, clean state.

In cases where beds are devoted to the growth of Lilies, it is almost needless to say that the tallest should be arranged in the centre, but what I would specially point out is how greatly the effect may be heightened by planting amongst them an equal number of *Gladioli*, the latter of which come into bloom later and last on till the autumn. I know of no grander bed or group of plants than these two make combined, and being of the same habit of growth they associate well together, besides which, the roots of the one never at any time unduly rob the other, and the treatment which they require is much about the same. I have just completed a border

Pachystoma Thompsonii (much reduced).

containing some hundreds of bulbs planted in three rows of each sort, and they will be worth seeing next summer and autumn; and those who would like to make some change from the present system of embellishing the flower garden will find that a few masses arranged after the same manner will be a source of much interest as well as objects of great beauty. Once planted, they may be left alone for years, and each season they will improve in strength and increase in numbers, when a division may be made to furnish other parts of the grounds. If the Gladioli are put in now they should be 6 in. below the surface, and surrounded with a pinch of sand in the same way as advised for the Lilies. To render all safe and secure from frost, a top-dressing of leaf-soil scattered over the bed will make snug for the winter, and if not planted at once the best way is to bury them in dry sand in a shed till March, so as to keep the air from them and maintain them in their present plump state.

As regards Hyacinths much that has been said respecting the above, so far as the preparation of the beds, planting, and soil is concerned, applies equally to these, as they, too, like plenty of depth and a rich run for their roots to ramify, and therefore it will not be necessary to go over that part again. These being plants of low growth always look best in small circular beds well raised in the centre; and if a neat, compact plant of some kind is placed at that part the effect is considerably added to, and a much better finish imparted. Not only is this the case, but an elevated surface lies drier and warmer, which is greatly in favour of bulbs having to lay in the ground all the winter. For borders groups of three look best, and the spaces between filled with Alyssum, Aubrietia, Pansies, or any other spring-flowering plants, and if backed up by shrubs, all these show up to great advantage, and make a border the most interesting and enjoyable part of a garden.

Bulbs in Pots.—Nothing imparts more floral life to a green house than bulbs in pots, and amongst them all Hyacinths stand pre eminent; and coming in as they do when other flowering plants are scarce, they are doubly valuable on that account. The best effect is produced with these by growing three in a pot, which may all be of one kind or otherwise, so as to show each other up, a plan of growing them that is particularly suitable when they are required for vase or window decoration. 6-in. or 7-in. pots are quite large enough for the purpose, as Hyacinths that are properly fed after they become well rooted will do just as well in these as in others of larger size; and, indeed, very often considerably better, especially when in the hands of those who are not well acquainted with their requirements as regards water, &c. The soil most suitable for this class of bulbs is a good fibry loam, with about a fifth of leaf mould, and just a dash of sand added, with which and proper drainage they cannot fail to do well. Why many do not succeed with them is in giving too stimulating a compost, whereby the base of the bulbs become injured by coming into contact with manure, a practice in all cases to be avoided, as it is almost certain to engender rot, and any assistance they may require can always be given in a liquid form, from which there is no danger of them suffering in the above-named way. In potting I make a practice of putting a pinch of sand under each bulb, as I find that it is a great help in warding off any tendency to decay, and in all cases, therefore, I should advise this being done as a precautionary measure, whether they are grown in pots or the open ground. The best situation for Hyacinths till they shoot into growth is a cold pit, or under the shelter of a north wall, where they can be covered over with Cocoa fibre, leaf soil, or anything of that kind, and protected from wet by means of an old light. In a place of this kind the tops progress slowly, and afford ample time for the roots to get well in advance, which is a great point gained towards securing fine spikes of flowers. Although the bulbs require to be buried and kept dark in the above-named way, they must not be kept under too long, or be too suddenly exposed to the light and air, otherwise they become drawn and bleached, and the transition, being so great, the tips of the leaves become injured and die off. The safest course is to remove the covering by degrees, that they may be gradually inured to the change by protruding their heads through; or if this has not been done, the next best plan is to throw a mat over the glass for the first few days, that what light they get may not be too strong or sufficient to hurt them.

Squills are a lovely class of plants specially adapted for pot work, and should not be forgotten, the peculiar shade of blue and the general formation of the flowers being of the most pleasing description. *S. bifolia*, *S. sibirica*, and *S. præcox* are the best and earliest, and are exceedingly choice in bouquets, or to work up for button-holes.

Crocuses, too, although not very enduring, are among the first harbingers of spring, and go far towards making a greenhouse gay, or to give a cheerful aspect to sitting room windows. To crowd them in pots, as is generally done, is to spoil half their beauty, as the delicate pencilling and the exquisite form of the petals are partly lost or hidden, instead of standing out clear and distinct as

they should. Five or six in a 4½-in. pot is quite sufficient, or double that number in a 6-in. pot; but for general purposes they look best in the smaller size, and should be placed at equal distances apart.

Tulips are likewise very amenable to pot culture, and make a gorgeous display at a very cheap rate, as the bulbs of some of the most showy may be had at a low price; and as they bear forcing well, and last long in perfection, they are very desirable for spring decoration. Tournesols are the easiest grown and the most brilliant, and for variety, *Rex Rubrorum*, *Duc Van Thol*, and *Mariage de ma Fille* are all good and more showy than the single kinds. Pot these in a pot in any soil, and treat them the same as Hyacinths.

S. D.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Fuchsia microphylla.—This Fuchsia well repays a little cultural care. When well grown in 6-in. or 8-in. pots it proves a most useful subject for either conservatory or room decoration during the late autumn months. Its habit is graceful, its foliage, though small, is dense and glossy, and its pretty rose-coloured flowers are produced in such profusion as to render it very ornamental. Nevertheless, like many other old-fashioned plants, it is but seldom seen in large establishments. It would, however, prove very acceptable when the beauty of the open-air garden is past, and when flowering plants are at a premium, for it is just at that time when the Tom Thumb Fuchsia, as it is called, is at its best. It should be placed in the open air during the summer months and liberally fed. It then becomes sturdy, and flowers in every way better than when grown under glass.—*J. C., Byfleet.*

Deep Pots Best for Palms.—We planted our Palms out-of-doors this year for the decoration of the flower garden. They were turned out of their pots, and in taking them up the other day I found that they had sent down roots perpendicularly to the depth of from 2½ ft. to 3 ft., about the size of straws, thus proving the necessity of using deep pots for this class of plants. Dr. Bennett, I believe, was the first to introduce deep pots, and without doubt his plants are perfection as regards health. I have noticed, too, that Palms planted out indoors in rich, deep soil, retain their leaves longer in perfection than those which are grown in ordinary pots.—*D. S. GILLET, Weybridge Heath.*

The Cape Pond Weed as a Room Plant.—Few plants have gained a wider popularity than this beautiful aquatic. The ease with which it may be grown, combined with the beauty and delicious fragrance of its flowers, render it a subject very suitable for cultivation by all classes. We saw some boxes of it the other day growing in a cool house at Trinity College Botanic Gardens, and producing an abundance of its lovely flowers. The boxes were ordinary square wooden ones, half filled with good loam, in which the Aponogeton was planted, the remaining portion being filled with water. Mr. Burbidge informed us that they were only planted about six weeks, yet the plants were growing and flowering freely. We also found here this same plant growing in an ordinary inverted bell-glass, and we learned from Mr. Burbidge that he had grown and bloomed it most successfully in this way on several occasions in a sitting-room. The bell-glass is half filled with loam, in which is placed the Aponogeton; the loam is covered with fine sand, and the remaining portion of the glass filled up with water. An ordinary flower-pot—if nothing better can be had—will do to place the bell-glass in. It will be advisable to flood the water occasionally, say, three times a week with a watering pot on which a moderately fine rose has been fixed. The sand will keep the water from getting muddy. It treated in the way just described, this charming plant may be grown and flowered most successfully in the sitting-room.—*Gardeners' Record.*

How to Propagate *Cyperus alternifolius*.—The best way to propagate this useful decorative plant is to select some good heads, cut them from the parent plant with 1 in. or 1½ in. of stem attached to them, draw the leaflets through the hand, and cut them back to half their length; then put them into pans of water plunged in the propagating bed, keeping the water from 85° to 90°. In a very short time roots and shoots will start from the base of each leaflet. When the growths are about 1 in. long, they should be potted singly in 2½-in. pots in leaf-mould. Keep them well moistened, and when the pots get filled with roots, shift them into 3-in. ones, using a compost consisting of equal parts loam and leaf-mould. If grown as I have directed, they will soon make good plants for decorative purposes.—*W. DANIELS, Trowdeswell, Goulhurst.*

Flowering Bouvardias in Heat.—I am fully aware that *Bouvardias* will bloom after a fashion even late in the autumn and winter in a greenhouse temperature; but, having tried them both

with and without heat, I recommend that which I have found to give the best results. "Cambrian" says that in advising their being flowered in a brisk heat I recommend an expensive system. This seems like trying to make out a case. People who require flowers in any quantity through the winter have a place sufficiently heated to force them in, and it is no additional cost to give the plants in question the room which they want. Some of those who now write about Bouvardias would appear to have only recently become acquainted with them. Greenhouse treatment was what they received when first I knew and grew them, now over twenty-five years ago. Thus managed, like many other growers, I gave them up as not equal to other plants that took no more room or attention. Those who are satisfied with a flower whatever its condition may be have a perfect right to follow their own inclinations. But if "Cambrian" and others who advocate blooming these plants during the two last months of the year and through the winter—which is the time I wrote for—would bring their greenhouse-grown flowers to Covent Garden, they would discover their value, or rather want of value, for no one would give anything for them, from the simple fact of their being so deficient in purity of colour and general appearance as compared with those brought out under warmer conditions, to say nothing of the plants grown in heat producing double the amount of flower in a given time, a fact alone well worth consideration.—T. BAINES.

— Although I appreciate Mr. Baines' notes on most subjects, I differ from him very much as regards Bouvardia culture. If my memory serves me rightly I think his last note on these plants last season was to the effect that he found them not to produce many flowers beyond those formed on the plants when planted out. I, however, still say that good and useful Bouvardias can be grown and had in bloom all through the winter without subjecting them to stove heat. From plants planted out and lifted in autumn in 1878, we had Bouvardias in bloom till the end of February, and they were never subjected to a higher temperature at night than 50°, and that only on mild nights. This season I have grown a larger quantity than hitherto; some we cut back in March, and put them in heat to start them for blooming in summer; others we cut back in April, potted them, and put them in a cold pit to start, and when the summer was far advanced, put them again in some cold pits, taking off the lights by day and on all favourable nights, only putting them on when the rain was too much for them. These are and have been for some time past, full of bloom; others, cut back at the same time, were planted out with some cuttings, which were struck in spring in a pit, so that we could put the lights on them if needed. Last season they never had a light over them once from the time of planting to the time of taking them up, which was September 6th. They were then put into a cold pit, and when established every point was pinched off them, and now some of the cut-back plants are showing from forty to fifty trusses of bloom, some shoots showing three and four each. Now none of these plants have ever been in a higher temperature at night than 50°, and sometimes 45°. I only name this to show that Bouvardias can be grown successfully on the cool system. The sorts I grow are *B. elegans* and *B. Veelandii*.—J. C. F.

THE KITCHEN GARDEN.

DEEP CULTIVATION.

THE cultivation of the soil is by many considered to be a commonplace affair, and although strength of arm is more required than skill in trenching, digging, or ploughing, I am confident that cultivators who get over this part of their work by merely putting a fresh surface on the ground, leaving the real rooting medium unbroken, will have an equally easy task in harvesting their crops. We may help crops by surface stirring after they are planted or sown, but it is only when the ground is bare that we can lay the foundation of really satisfactory growth. The value of deep cultivation is frequently discredited through not sufficiently considering the nature of the soil to be operated on; when the subsoil is hard or inclined to a clayey adhesive character, it follows that if too much of it is brought to the surface in a crude state, more harm than good for the first year or two may be the result, as tender crops requiring a friable soil or seed bed may not succeed so well as before, although the land would doubtless be ultimately benefited by the deep culture. This is not, however, the fault of the trenching, but the mode in which it is done.

We are at present trenching up some old beds of Strawberries and land that has been occupied by bush fruits for many years. We find in this case the lower spit looser and more friable than that of the top; we therefore bring the whole of the lower spit to the top, and after loosening the bottom of the next trench, we pack in the

old Strawberry crowns and runners and green garden refuse of any kind, and a large quantity of fresh long stable litter from which the Mushroom material has been eliminated. This takes a considerable time to decay; the land feels the benefit of such a dressing for years, and such a depth of loose enriched feeding ground is provided that, let the seasons be ever so dry, the crops can find moisture below them; and if extremely wet, the surplus water passes rapidly away, as the rough material put in acts as drainage, until, rotting away, it eventually becomes food for succeeding crops, to be again brought to the surface as soon as fertility there begins to decline.

We have some land close by that has only been broken up a few years, and although originally all one sort of soil it has not yet been sufficiently cultivated to allow of the lower spit being brought to the top with any advantage. We shall, therefore, instead of bringing it to the top, fork it over in the trench, working in leaf-mould, ashes, or old potting soil, which is of a light sandy character, and after a few years a sufficient depth of friable soil will be obtained to suit any kind of crop. By this means the heaviest and most unmanageable soils will become the very best that can be obtained for vegetable or fruit culture, as light sandy soils that are easily got into working order are, as a rule, soon exhausted, and need more frequent additions of rich farm-yard manure to enable them to produce fine succulent vegetables in dry seasons; and fruits—whether Strawberries, bush fruits, or standard trees—never attain the size and vigour in light soils that they do in loams in which clay predominates more than sand. The advantages of getting this sort of work done at this season of the year are manifold, as the winter rains pass readily through the newly-moved soil, and enrich it, while the frosts pulverise the surface, and by the ordinary seed-time it is fit for being planted or sown with any sort of crop with every prospect of success. Any kind of refuse or garden litter may be profitably used as manure, and what would make rubbish heaps, if buried deeply, soon becomes converted into food for future crops.

JAMES GROOM.

Garden Thyme.—When looking through the garden at Croome Court the other day I noticed amongst the herbs a good bed of Thyme, not injured in the least by the frost. I asked, How is it this looks so well? The reply was "We always sow in spring a small quantity of seed which grows fast. The produce of this we pull up for drying, so as not to cut the plants in the beds too late before winter, leaving plenty of well-ripened growth, which resists the effect of frost better than soft shoots."—J. C. F.

Chickens v. Slugs.—I have in former years had a great dislike to poultry of any kind in gardens, but the past season has been so exceptionally favourable for the ravages of slugs, that we have been glad to avail ourselves of any means of reducing their numbers within our reach; and having a brood of chickens that always made their way on to the cultivated plots as soon as set at liberty, I have since allowed them to have free range of our kitchen garden, and at the first break of day they may be seen regularly searching the rows of Cabbages, Broccoli, &c., and picking up slugs, worms, and grubs, and without doing any damage, as they betake themselves to dry spots under large evergreens to scratch and work among the dust, as the stiff soil of our kitchen garden has not been dry enough this year to suit their taste in that respect. I find young chickens the most industrious in searching after insects and other garden pests, and where these abound I feel confident that poultry in limited quantities might with advantage be admitted to the kitchen garden for the greater portion of the year, as during the hottest months, when bush fruits and other crops which they would be most likely to destroy are ripening, the slugs are least to be dreaded, and the poultry could then be excluded. In almost any position broods of young chickens might be utilised by keeping the hen in a coop near the spot where the chickens were required to search. They will soon find out where there is any food for them, and any ant hills, if first loosened up with a spade or fork, will soon be cleared of both the ants and their eggs, as chickens are especially fond of them.—J. G. L.

Veitch's Autumn Giant Cauliflower.—This is very fine at present with us, the heads being large and close. Both it and our Brussels Sprouts are remarkably free from club, having been sown and pricked out in heavy soil brought from a distance, while our other Cauliflowers, &c., sown in our common garden soil have been very much affected with club.—J. MILLER, *Clumber*.

Criterion Pea.—Amongst several late Peas grown here, I find none to surpass Criterion and Ne Plus Ultra for productiveness, for flavour, and colour when cooked. We have to-day (October 20) gathered a good dish of Criterion from a row from which we gathered the first dish on August 9, thus showing its bearing propensity. Others sown late in June are now carrying a heavy crop of well-filled pods, the contents of which are now fully appreciated; but I cannot bear out "Reader's" experience of Culverwell's Prolific

Marrow; with us it is much inferior to the above both in flavour and colour. Although a very productive cropper, it has not such large, well-filled pods as the former. Were I asked to name the two best late Peas, I should say Criterion and Ne Plus Ultra.—G. S., *Sandbeck Park*.

THE FLOWER GARDEN.

VARIEGATED GRASSES.

COMPARATIVELY few Grasses possess true variegation, if we take into consideration that they constitute one of the largest families of plants, and also one that has the widest distribution. If we omit the white-grooved leaves which characterise several genera, one per cent. of all known Grasses would include all the variegated forms. The variegation usually consists of longitudinal striations, or in one instance, of cross bars of white or yellow, or rarely red, upon both leaves and sheaths. The red colour is sometimes due to the presence of colouring matter in the leaf, but more frequently to a bronzing of the foliage by exposure to strong light. In the majority of cases, the varieties have a weaker constitution than the normal forms; but to this exception occur in the parrot Maize and the striped Bamboo (*B. striata*), where they, under similar conditions, attain the dimensions and vigour of the typical plants. Generally speaking, those plants in which the green colouring matter is most wanting recede further from the type in constitution, as it is only through the agency of this substance that the plant is enabled to add to its fabric. In some, the variegation is permanent under all circumstances, while in others it is very transient, often running out and becoming green under conditions favourable to luxuriant growth.

It is only recently that any attention has been paid to variegated Grasses, or indeed, Grasses of any description, except for lawns, at least so far as horticulture is concerned, though from their many attractions they deserve a prominent place in all gardens. Probably the best known and the most ornamental is the Ribbon Grass (*Phalaris arundinacea* var.). Its variegation, which is constant, is much improved by cultivation; it is also useful both as a border plant, and for indoor decoration, and, as it delights in wet places, it might be used with advantage as an aquatic or bog plant. The type is a true aquatic, inhabiting stagnant pools and ditches, and is with the exception of the common Reed (*Arundo Phragmites*), the tallest and handsomest of our native Grasses, frequently reaching 8 ft. in height, with long tapering rosy panicles. There are two species of dwarf white variegated Grass at present used for ribbon-bordering, namely, Rough Meadow Grass (*Poa trivialis* var.), and Cock's-foot Grass (*Dactylis glomerata* var.); the former, which is an erect growing plant, very often reverts to the type during wet seasons; the latter is a spreading plant with coarser foliage than the former, but its variegation is more permanent. They are both native Grasses, which also include five others deserving of notice; these are Soft Meadow Grass (*Holcus mollis* var.), a plant with downy glaucous foliage striped with creamy-white, requiring a moist sandy soil, and to be transplanted annually; Fox-tail Grass (*Alopecurus pratensis* var.), which forms a hemispherical tuft of long pendulous leaves with yellow and white stripes, which are often confined to the margins only; Melick Grass (*Melica uniflora* var.), a dwarf plant 6 in. to 9 in. in height, with slender recurved leaves with pale yellow stripes, the innermost of which frequently become entirely yellow; Bent Grass (*Agrostis vulgaris* var.) which, like the type, is a creeping plant, and unless kept within bounds, is liable to become a nuisance on light soils; its variegation is nearly white, and irregularly distributed, but embraces nearly half of the foliage; and lastly, the Blue Moor Grass (*Molinia cœrulea* var.) which is the most elegant of the five. Its leaves, which are rigid and erect, and form dense tufts 1 ft. to 2 ft. in height, are distinctly marked with canary-yellow stripes, the flower stalks and branches of the panicle are similarly marked, while the spikelets remain a bluish green as in the typical plant. In addition to the varieties of *Enhalia japonica*, *Arundo Donax*, *A. mauritica*, and *Zea Mays* described at p. 322, there are two variegated forms of the Pampas Grass, known as *G. argenteum marginatum*, with marginal golden stripes; and *G. Stenackeri variegatum* with distinct white margins, both of which are highly ornamental, but on account of being difficult to propagate they remain very scarce.

Of the dwarf arborescent Grasses, the most noteworthy variegated forms are Fortune's Bamboo (*B. Fortunei* var.), which is of a shrubby habit, with thickly set silvery striped leaves; and the green striped Bamboo (*B. viridis striata*) a taller plant than the preceding, with larger leaves of a primrose yellow colour striped with green. These and all the foregoing are quite hardy. Among those requiring a warmer temperature we have the variegated Creeping Panicum (*Oplismenus imbecilis variegatus*), which is so useful for trimming hanging baskets, for vase decoration, or to associate with cut

flowers. As a basket plant it forms pleasing combinations with such plants as *Coccospyselum discolor*, *Impatiens flaccida*, or *Æschynanthus miniatus*. Its variegation is of the purest white when grown in the shade and in a moist atmosphere, but when exposed to full light it is richly suffused with rosy crimson. Striped Crab Grass (*Stenophyllum glabrum variegatum*) is also a creeping Grass, forming runners 3 ft. to 4 ft. in length, and giving off a pair of tufts of leaves at each of its joints, which occur at regular intervals. Its leaves are strap-shaped and profusely striped with creamy white, those of the central tuft being much larger than the lateral ones. It is a more robust plant than the preceding, and very different in character, but may be used for the same purposes. The typical plant is used as a lawn Grass in Brazil, for which purpose it seems to be well suited. The silvery plaited Panicum (*P. plicatum* var.), is a tall growing plant, with irregular white stripes down its broadly ribbed leaves, and white panicles.

Several Grasses present a bluish-white or hoary appearance, which differs from true variegation by being a surface covering only. Some few of this class are very effective in combination with darker foliage. The principal are blue Fescue Grass (*Festuca glauca*), spiny Grass (*F. punctionata*), glaucous Sheep Fescue (*F. ovina glauca*), blue Meadow Grass (*Poa caesia*), glaucous Meadow Grass (*Poa pratensis glauca*), large Lyme Grass (*Elymus giganteus*), European Lyme Grass (*Elymus europæus*), and Seaside Wheat Grass (*Triticum junceum*).
C. M.

FLOWER GARDENING IN BAD SEASONS.

FOR several successive summers we have had anything but favourable weather for the style of flower gardening which has for some time, and until recently, been the general fashion. It is no doubt still looked upon by many as the highest development of floral art, and so long as it is kept within due limits and confined to places where it will not be incongruous with the surroundings, it is not so objectionable. In order that these displays can be considered satisfactory with the description of plants employed in these summer combinations, not only should the weather in spring be genial, but the summer seasonably warm and prolonged. If in spring the weather is cold and otherwise unfavourable to the progress of the plants immediately after being planted out, however bright the effect may ultimately be for a time, its duration is far too short to compensate for the waiting and amount of labour incurred. This is nothing more than has often been urged before by those who were not unqualified advocates of the system, but the ungenial seasons we have lately experienced, and more especially the present, have done much to convince those who have hitherto refused to consider the subject reasonably. There invariably appears to be an infatuation attending fashion, which for a time goes far to obscure even the most obvious facts, and fashionable flower gardening has been no exception to the rule. The failure has been greatest where such plants as *Pelargoniums* have been extensively employed, and which in most places have presented a thicket of leaves with a paucity of flowers. In many cases the beds of spring flowers were in their best condition just at the time it was necessary to remove them, so as to make room for the summer occupants; and in not a few instances, if the spring subjects had remained undisturbed the general effect would have been better. The carpet bedding has fared better, except in the case of the tender plants, such as *Coleuses* and *Iresines*, which have been failures generally. The hardier subjects have succeeded fairly well, on the whole; carpet bedding has been much the best both the last summer and more particularly the present. Some of the arrangements in this style are undoubtedly very effective and beautiful where the patterns are not too formal. Several narrow scroll designs I have seen, whose gracefully curved lines, formed of sufficiently subdued colours, were very elegant, and nothing in their way could well be more charming. There is no doubt that these successive unfavourable seasons for the ordinary description of flower gardening, now so long practised, will have the effect of bringing the carpet bedding style more into general favour; but it is not to be supposed that this kind of arrangement is likely to supersede the use of flowering plants. Flowers have a charm, but, irrespective of this, there is a feeling associated with the very name that commends them to all who love or take a real interest in gardening, and I cannot believe that even fashion can, for any length of time, induce many to tolerate the misnomer of a flower garden without flowers. I think that carpet bedding must always hold a subordinate position to flowers, independent of the amount of labour which it entails in propagating and growing plants extensively. Still, there is no reason why a combination of leaf and flower colouring should not be carried out, such as has not hitherto been attempted; I do not mean the associating of strong-growing plants more or less coarse in habit, but a judicious selection of the most elegant foliaged plants with such low-growing subjects as may be chosen for their form, colour, and continuous disposition

the sun may yet impart, the radiation of the walls will make it the more effective. Push on planting, lifting, and root-pruning, as the present is the best season of the whole year for such work, a fact proved by the rarity with which trees now operated on fail to produce a full crop of fruit the following season. Gooseberries and Currants, being divested of foliage, may now be pruned. It is usual to defer the pruning of Gooseberries till spring, because birds are apt to make an onslaught on the buds, but I look upon such a postponement as an invitation to the birds to attack them, and therefore recommend that pruning be done now, and if afterwards the trees are splashed over with a mixture of soot and lime, with cow manure added to cause adhesiveness, the composition will not only be distasteful to birds, but also kill Lichen and Moss, which usually abound on neglected fruit bushes. When pruning, select the best-ripened wood for cuttings, which may be tied into bundles and heeled in to give profitable employment in bad weather in preparing them for insertion, which should be in rows 1 ft. apart and about 6 in. asunder in the rows. All the buds should be picked out of that part of the stem that is inserted in the ground, or there is a tendency to produce suckers, and each tree is always best when grown with only a single stem. Old plantations of all kinds of small fruits will repay any attention that can be afforded them at this season, such as the thinning out of useless naked wood, surface forking the ground, and afterwards giving it a good dressing of well-rotted manure, to be left on the surface to be washed in by the rains. Raspberries especially should annually have such a dressing. The season being so late, there are yet several kinds of Apples and Pears to be gathered, and as they are now in danger from severe frost they should be got in, ripe or unripe. Keep the fruit room well ventilated on every favourable opportunity till the fruit has become thoroughly dry, but afterwards preservative conditions are best assured by the maintenance of a somewhat confined atmosphere.—W. W.

Extracts from my Diary.—November 3 to 8.

FLOWERS.—Placing bedding plants, Primulas, Cinerarias, Cannas, and Bouvardias in Vinerics. Re-arranging plant-houses. Sponging Poinsettias and Stephanotis. Picking dead leaves off Pelargoniums and bedding plants. Cutting back old plants of Pelargoniums, and placing them thickly in boxes in Vinery.

FRUIT.—Cleaning Peach trees in early forcing-house. Tying Raspberries to wooden frame, forming the letter V with the canes. Mixing up paint for dressing Peach trees, composed of clay, sulphur, soap, soot, and Gishurst Compound. Started pot Vines.

VEGETABLES.—Preparing cold frame in which to plant Cauliflowers. Getting in next Mushroom-bed, and looking over others, cutting those fit for use. Sowing Hathaway's Excelsior, Vick's Criterion, Little Gem, and Acme Tomatoes in heat. Pricking out Cauliflowers from seed-beds into frames to stand the winter. Digging main crop of Beet, and storing it in clamps. Cutting all Self-protecting and Autumn Giant Broccoli ready for use. Chopping up Cauliflower stumps, and manuring ground with them for digging. Sowing Barghley Perfection Tomato in pots for planting out for early spring work. Spawning Mushroom bed in house, and making up first bed outside in the shape of a mound 20 ft. long and 5 ft. high. Sowing Osborn's French Bean. Tying and thinning winter Cucumbers. Digging south border for Peas. Sorting over Potatoes in store-room.—R. G., *Burghley*.

Women as Horticulturists.—The practical difficulties with young women searching for a vocation is that they have no capital, no special training, little knowledge of current commercial needs, and no disposition to enter untried fields of labour. They are ceaselessly demanding new avenues for employment, under the impression apparently that by talking about them vigorously these new avenues will open of their own accord. Assuredly fruit-growing, flower-culture, and kindred pursuits offer no great obstacles to young women with a small measure of determination and a little activity of imagination. The great point with us all is to be able to think out things, and this is what we mean in this instance by imagination. Neither men nor women are likely to gain much success in established vocations, much less enter upon untried ones, unless they have ideas, the power to construct, to form, to plan, to discover the relations between facts and possibilities of facts, to detect significances and follow them to their logical outcome. In flower-growing, however, there is this advantage—many ladies have natural taste and a little smattering of the art, and hence it would not be difficult for them to gain sufficient knowledge from books and practical experience in their own gardens to make a test of the suggestion which the writer in "Macmillan" makes; and eventually training schools may be established in which young women could enter. The thing is to make a beginning; and to make a beginning the very first requisite is practical intelligence.—*Appleton's Magazine*.

TREES, SHRUBS, AND WOODLANDS.

PRUNING AND LOPPING TOWN TREES.

As the season for lopping and pruning trees where necessary is approaching, a few remarks on the manner in which this work should be done may not be out of place, and this is rendered the more necessary in town gardens where trees are scarce, and where they are so frequently ruthlessly and mercilessly hacked and hewn by inexperienced persons as to become miserable eyesores instead of what they should be—handsome and acceptable objects. In traversing London it is distressing to see trees which, with proper management would have formed beautiful specimens, reduced to offensive skeletons or worse than useless pollards, and the evil of which treatment is the more apparent now when they are denuded of foliage. The pleas put forward for thus mutilating trees are various, as, for instance, the obstruction of light, injury to adjacent roads, or some Utopian sanitary idea. In the case of young trees it may be to protect them from injury from high winds, or with the object of inducing a spreading habit. These reasons are frivolous in every case, except where trees are planted in places totally unsuited for the purpose. In the case of London squares an ample roadway surrounds them, so that trees planted at a proper distance within the fence will in no way interfere with the light, whilst in regard to the sanitary aspect and the deterioration of roads proper scavenging is an easy remedy. With respect to newly-planted trees in streets and elsewhere, they should have such supports as to render pruning unnecessary; their natural habit being thus preserved, which, in my opinion, is the special feature needful in well-managed trees. Another important matter which should also be taken into consideration is that in many places where from thirty to fifty years have been sufficient to produce fine specimens, it would now probably require a hundred, even if that period would suffice to bring to the same forward state, London proper having been during the last half century imprisoned by outer or greater London, rendering the growth of trees within it less satisfactory. It is, therefore, the more necessary to preserve intact the few which remain in good condition.

The list of trees suitable for town planting is not a long one, and these require but little pruning, and that judiciously done. It is necessary that the lower branches should be removed to a sufficient height in order that they may not interfere with the carriage traffic in the streets; it is also essential that dead branches should be cut out; but, further than that, there is probably not more than one case in a hundred in which it is necessary to use pruning tools. Plane trees are now admitted to be amongst the most useful for town planting, and I would urgently recommend that they be allowed to grow naturally, that is, without any pruning whatever. I have particularly noticed that those which have in no way been interfered with are by far the most beautiful. The principal care required being to protect their stems from injury and keep them in an upright position, this can be ensured by suitable guards and proper care in staking; should there be two leaders, the weakest should be removed and the remaining one so tied that it may be induced to form the main stem. Under no circumstances should Planes be headed back, that is, have their leading and lateral stems cut down; of all systems of lopping and pruning, none are more objectionable, unsightly, and mischievous; occasionally a few of the weak branches may be removed to give air and light to the head. This is only necessary, however, where from the effects of soil and situation such growth is produced in abundance. The Plane taken altogether may be safely considered to require no pruning. Next in rank as suitable town trees stand the Poplars; most of the spreading kinds, when compared with Planes, may be pruned with impunity without damaging their general character; still the same course should be followed as recommended for Planes if we would retain their special features. These trees will be found to have a tendency to grow very much out of the upright, whatever care may be exercised in staking them when young. It is therefore absolutely necessary to shorten those branches which have as it were a tendency to overbalance the proper contour of the tree; rapid growing trees are more liable to this deformity than others. This is also the case with trees which are so placed as to have the light partially obstructed on one side, the curvature being caused by the greater rapidity of growth on the darkened side. In order to counteract this, as before mentioned, the branches should be cut back to such a position as will leave sufficient wood to replace the limb removed, and never to a point of the branch that is perfectly bare, as that would induce the growth of a number of small shoots which would not only be useless but greatly disfigure the tree.

Planes and Poplars which may have spread their branches too near dwellings, may have them shortened in the same manner without in any way impairing their general appearance. The

Plane once damaged by unskilful pruning never, as a rule, regains its natural form, and is often worthless as a tree. Two other trees, namely the Lime and the Chestnut, are also extensively planted in towns; indeed they are great favourites with many; they burst early into leaf, and as it were chase away the winter, the remnant of which is always reluctant to leave us in early spring. They are better adapted for planting in the outer circle of large towns than in thickly-populated districts, in which latter they do not thrive; moreover, they lose their foliage early. No trees are used worse than the Lime; they are pollarded or lopped in all kinds of hideous forms, or pruned into screens of various shapes, examples of which meet one at almost every turn. Few trees are handsomer in form than the Lime when allowed to grow naturally, and being dense in respect of foliage, would answer every purpose for which inexperienced persons think it necessary to treat them as stated above. The only pruning required is to take out the weakest branches close to the main stem, of which, in well-grown trees, there are usually a large quantity. If, as may sometimes be the case, it is not desired that the trees should exceed a certain height, they can be stopped without spoiling their beauty, a property possessed by a few kinds of trees only. The Chestnut with its ridged wood, is another tree which requires no pruning, except in rare instances; when one bough lies upon another, the one causing the least change from a natural appearance may be removed. The Sycamore, Elm, Acacia, and, indeed, all kinds used in town planting, should only be pruned with the utmost caution, and that when absolutely necessary only. Certainly very many trees have been perfectly ruined by too free a use of the saw and knife, and it may often be observed that young trees which appear extremely vigorous for a few years after being planted lose a good deal of energy at the end of ten or twelve years, and are quite unable to recover the effects of the severe pruning to which they may have been subjected during the first six or eight years. This is more especially the case with trees the sites for which have been prepared with more than ordinary care. I maintain, therefore, that trees should, as a rule, be allowed to grow freely and naturally, and if pruning should be in any way requisite, to wait until the trees are thoroughly established. In taking off branches, especially the larger ones, the cut should be under bevelled, to prevent moisture accumulating on the stump left, which would cause decay and injury to the tree. They should also be cut at a distance of from 3 in. to 1 ft. from the main stem, never quite close to the tree, the distance being in proportion to the size of the limb taken off. These remarks are specially adapted to the management of trees planted in streets, squares, parks, and other public places.

C. DENNIS.

WOODLAND WORK FOR NOVEMBER.

PLANTING will be the principal work of the month, and every fine day should be taken advantage of to push forward that work with as little delay as possible. By planting the wettest portions during fine weather, and leaving the light and gravelly soils for the more unfavourable seasons, little time need be lost so long as frosts keep off. Exposed situations upon light soils should be filled up before winter, and the ground made as firm as possible to prevent the plants being uplifted by frosts. When such land is planted late in the spring the trees are apt to suffer very considerably from summer drought.

Mixed plantations may be thinned after the middle of the month, Oak being reserved for spring, felling when the bark will run freely. Very few of the winter-felled trees, except Larch, should have their bark left on them, as this decays rapidly and retains the water, and also harbours injurious insects. Lime, Plane, Beech, Maple, and Sycamore should be cut up early and set up for seasoning. In thick plantations only experienced hands should be entrusted with tree-felling; and the timber should be cut off as close as possible to the ground with the cross-cut saw, grubbing being impracticable without doing considerable damage to the roots of others.

Gather tree-seeds as they ripen and attend well to the keeping of such as are not sown at once. Where the cones of Pine and Fir trees—Scotch, Spruce, and Larch—will shake easily from the trees, these may be gathered at once and well dried before being put away in heaps. By being thinly spread out and occasionally turned they will dry rapidly.

Old spreading hedges may now be ribbed in where the situation is not too much exposed, but where such is the case the operation is better deferred until early in the spring. Laying or plashing may also be proceeded with, and young Hawthorn hedges may still be planted out. Quicksets which have been two years transplanted may be inserted in double rows about 6 in. or 8 in. apart and the same distance in the lines, and afterwards cut off near the ground. If allowed to grow for two years they may then receive an annual trimming, about 6 in. of top growth and 2 in. of side growth being

left each time. In this way, upon a favourable soil, a good hedge may be obtained in six or seven years. Where the soil is too light and poor for Hawthorn, Beech may be substituted, but this should not be cut back at the time of planting.

Clear out watercourses and ditches and collect leaves, forming composts of all refuse vegetable and animal matters. The addition of some fermenting stable manure, old mortar, chalk, shell sand, or calcareous matter of any kind, will greatly enrich the compost if it be turned occasionally. Lime used in compost has a much more marked effect upon a rotation of crops than when applied alone. Within certain limits all composts containing calcareous substances enrich with age.

Falls of coppicing should now be allotted ready for sale. The sooner these are sold the greater the opportunities afforded to the purchaser for making an early clearance. The smaller the lots the greater will be the aggregate price. Clearance roads should be staked out ready for brushing, or bottoming with faggots, and all boundaries should be distinctly marked with paint. Tillars should also be ringed with paint and numbered. The necessary restrictions as to times of cutting and clearance should also appear in the particulars of sales.

Draining, trenching, and holing for spring planting may still be continued in the woodlands; and in the nursery cleared spaces may be worked down for seeds and seedlings, or be roughly dug and laid up for a winter's rest. Strong layers of any kind may now be planted out in the woodlands; and before other layers are made the stools should be forked round, and should also receive a dressing of manure or fresh soil.

All wood-rides should be well brushed up preparatory to pheasant shooting, as nothing interferes so much with that sport as straggling branches hanging over and across narrow rides. All foresters who value their plantations should thus give every facility for killing those pests of their woodlands, viz., hares and rabbits.

A. J. BURROWS.

Age of Trees.—The late Mr. Menzies, deputy ranger of Windsor Park, than whom no one had studied trees more, has often interested me by information about the size and age of forest trees when with him amongst them. Much of this information will be found in his large illustrated work on "Forest Trees and Scenery." It was his opinion that it is impossible to determine even approximately the age of Oaks when the trunk is decayed. He thought that the shell of the tree near Cranbourne in Windsor Forest (where there are many similar shells of huge old Oak trees), which goes by the name of William the Conqueror's Oak, might probably belong to that date. Beech trees, he said, are not nearly so lasting; and though I often asked his opinion as to the age of the larger Barnham Beeches, his answer was always "Impossible to say." It may interest Mr. Heath to know that on Smith's Lawn, near the obelisk in Windsor Park, are the remains of a Beech tree larger than any of the Barnham trees. An account of this tree and of many other remarkable trees will be found in "Grigor's History of Arboriculture," published in 1868—a most interesting little book, and the best I know on the subject. I may add that the age of large Elm trees, being comparatively short is generally definitely known; the large Elm trees in Eton playing fields are little over 200 years old; a record of their planting is in the college archives; the Long Walk in Windsor Park was planted in 1688. Both these sets of trees are fast perishing from old age. Half the Elm trees in Eton playing fields have been replaced by young ones within my memory. Elms die first at the root, and are blown down generally before the trunk has begun to decay.—C. WOOLLEY DOD, in *The Times*.

The Size and Age of Trees.—I fear that much must be left to conjecture and tradition with regard to the age of the most celebrated of our forest monarchs. Herne's Oak, I think, is now a wreck if not removed, but in the memory of most of us it was alive if not in full vigour, a wonderful tree, to celebrate which Harrison Ainsworth wrote his historical novel "Windsor Castle." I believe visitors can still be shown the identical tree beneath whose branches the second Norman fell. King Charles II. has still his Oak, *i.e.*, supposing the sightseer sufficiently credulous to believe it; as to Rochester's Oak there can be little doubt. But who, in this tree-loving country, can tell us something that can be depended upon as to their age? No one. It may be said that when a tree is felled the number of rings which it contains will give within a year or two its age. True, so far as the test goes, but useless after a century or two has elapsed. Of course Mr. Vernon Heath has, with all of us who take delight in woods and forests, tried to verify that test. I have not seen the Barnham Beeches, and, therefore, can only argue by comparison, viz., that some very large handsome ones on our own land in Dorset, from all I can hear, were, to all appearance, quite as large

and beautiful full fifty years ago, and are now, at a rough guess, some of them 3½ ft. in diameter. These trees are in good soil but not particularly rich, and, being near the sea, may have been planted in line to break the force of the south-west winds, which, to us, are blighting.—EUGENE E. P. LEGGE, *Court House, Litton Cheenev, Dorchester.*

CALCULATING THE HEIGHT OF A TREE.

WE stated at the commencement of this article (p. 282, Vol. XV. of THE GARDEN) that it is easy to determine the height of a tree, if the ground around it is level and clear, with the very simple and inexpensive aid of two light rods (one 5 ft. and the other 10 ft. long), and a plumb-line or a string with a weight attached to it. It becomes somewhat more difficult, however, when the tree grows upon sloping or uneven ground, and when an obstacle occurs between the tree and the spot from which you can see it, such as a high wall, a spiked fence, or a broad ditch. Under such circumstances it is necessary that you should understand that branch of arithmetic called squares and square-roots. The square of any number is that number

Fig. 11.

multiplied by itself—thus, the square of 4 is 16, because 4 multiplied by 4 makes 16. The square-root of any number is some smaller number which, multiplied by itself, will make the number you have—thus, the square-root of 25 is 5, because 5 multiplied by 5 makes 25. The rule for finding out the square-root of any number must be learnt from a book upon arithmetic; it is too long to quote here, but it is readily committed to memory.

Referring back to fig. 2 (which shows the common way of drawing one line perpendicular to another by the “3, 4, 5,” method), we see there a triangle, two of the sides of which, as you know, are called the base and the perpendicular; the third or longest side is, in such triangles, called the hypotenuse. In triangles of this kind there is a curious relation between the lengths of the three sides, which always holds good and never changes; it is this, that if you add together the squares of the two shorter sides, and find the square root of that sum, it will give you the length of the longest side. Thus, 16 (which is the square of the base) added to 9 (which is the square of the perpendicular) makes 25; and the square-root of 25 is 5, which is the length of the hypotenuse. From this it will be evident that if you know the length of any two of the sides of such a triangle you can calculate the length of the third side. Thus, if the longest side is 5, and one of the shorter sides is 3, you subtract the square of 3 (9) from the square of 5 (25), and the remainder is 16; the square-root of this (4) is the length of the third side of the triangle.

Let us now carry this knowledge into practice, and proceed to measure the height of a tree growing upon higher ground than that upon which we stand. The 10-ft. pole must be clearly marked with divisions showing feet and inches, from the bottom upwards; and the 5-ft. pole must have a strip of wood 6 in. long fastened carefully at right angles across the top.

Where the incline is not very steep, as in fig. 11, stick the short pole exactly upright into the ground, at such a distance off from the tree as that the cross-piece shall be on a level with the bottom of the trunk; then measure the line A C, and, knowing the length of A B, we can calculate the distance from B to C. Next insert the longer pole at such a point between the short pole and the tree, as that the

top of the long pole shall be in a line between the top of the short pole and the top of the tree. Read off the length P M, and subtract it from P N (which is the same as A B, or 5 ft.), and the difference will be the length of M N. Now measure the distance from A to M; and, having got A M and M N, you can calculate the length of A N, which will be the same as B P. Lastly, as B P is to O P (which is the difference between 10 ft. and P M), so is B C to the height of the tree.

It will simplify the remaining examples of determining tree heights if we throw these last instructions into a more concise form, and substitute signs for words. The signs + and - are well known to mean “added to” and “less by;” thus: 4 + 2 = 6, means 4 added to 2 equals (or makes) 6; and 4 - 2 = 2, means 4 less by 2 equals 2. Then, the fact that a number is to be squared is indicated by putting the figure 2 at the upper right corner of the number to be squared, thus 9², or (if the number is represented by letters) AB². And √ indicates that the square-root of the number written under it is to be worked out; so that √49 = 7, means that the square-root of 49 equals (or is) 7.

Applying these signs to the instructions given in relation to fig. 11, they may be more concisely stated as follows:—

- a $\sqrt{AC^2 - AB^2} = BC.$
- b $PN - PM = MN.$
- c $\sqrt{AM^2 - MN^2} = AN = BP.$
- d $OM - PM = OP.$

Now we know that AB is 5 ft., and we find by measurement that AC is 21 ft., AM is 10 ft., and PM is 3 ft.; consequently, since AB is 5 ft., PN must be the same, and MN must be 2 ft. Hence, these statements of alphabetical letters represent the following figures:—

- a $\sqrt{21^2 - 5^2} = \sqrt{441 - 25} = \sqrt{416} = 20\frac{4}{10} = BC.$
- b $5 - 3 = 2 = MN.$
- c $\sqrt{10^2 - 2^2} = \sqrt{100 - 4} = \sqrt{96} = 9\frac{6}{10} = BP.$
- d $10 - 3 = 7 = OP.$

Whence we see that as 9⁶/₁₀ (BP) is to 7 (OP), so is 20⁴/₁₀ (BC) to the tree's height, which is 14⁶/₁₀ ft. nearly.

Of course, there would be no need to take all this trouble over a tree only 14 ft. high, which could be measured with a long, light rod; but, while the plan to be followed would be the same for a tree 200 ft. or

Fig. 12.

300 ft. high, the length in feet of the various straight lines would be naturally very different.

We next proceed to explain the method of determining the height of a tree growing upon a steep incline, which will be found illustrated in fig. 12.

With the 5 ft. pole in your hand, walk away from the trunk of the tree and find a place where the top of this pole, when stuck into the

ground, shall be on a level with the base of the trunk. Next fix the 10 ft. pole at such a further distance from the tree (and in a line with the short pole and the tree), as that the top of the longer pole shall be on a level with the top of the shorter pole and the base of the tree; AC on fig. 12 indicates the position of the longer pole. Next take up the short pole and put it into the place occupied by the long pole; AB will then indicate the position of the short or 5-ft. pole. Now place the 10-ft. pole in a line between the short pole and the tree, and at such a distance from the short pole as that the tops of the two poles shall be in a line with the top of the tree. Then look horizontally across the top of the short pole AB and read off upon the long pole MO the height MP; this measurement, being the same as that of NB, must be subtracted from AB (which is 5 ft.), and we thus get the measurement of AN. Now measure the ground line AM, and having AM and AN, we find, by the rule explained before, the distance NM ($\sqrt{AM^2 - AN^2} = NM$) which is the same as BP. Having just read off the length of MP we have only to subtract it from MO, which is 10 ft., and we thus get the length of PO.

With the lengths of BP and PO at our disposal, it is evident that a rule-of-three sum will give us the height from F to the top of the tree if we only knew the length of the line BF. This is readily found, inasmuch as BF is the same as CE, and CE is the base of the right-angled triangle ECA, of which the perpendicular AC we know is 10 ft., the hypotenuse AE we can measure and then $\sqrt{AE^2 - AC^2}$ gives us CE or BF.

Lastly, we have to work out the proportion sum, as BP is to PO, so is BF to the height from F to the tree-top, from which we have only to subtract 5 ft. (which is FE) and we arrive at the exact height of the tree.

In the example of tree measurement last given, it has been assumed that the incline and the dimensions of the tree will allow of the measurement being made in the way that has been explained. But instances will often occur in which the incline may be too steep or the tree too high to admit of this method being exactly followed; nevertheless the principles upon which the measurements are taken and the calculations are made will be the same, and the chief deviations from the method described will consist in the necessity for repeating the first stages of the observations by placing the 10-ft. pole a second or a third time beyond the short pole, each time making the 5-ft. pole take the place of the long one. W. T.

TRANSPLANTING TREES IN AUTUMN.

TRANSPLANTING is a subject of no little interest to proprietors who, as a rule, concern themselves a good deal about their woods and ornamental plantations. There are those who advocate transplanting in autumn, and others who maintain that spring is the best time for such work. Something can be said in favour of both ways, but much depends upon circumstances and the kind of subjects to be dealt with. It is safe and advisable to transplant in autumn, if it be done in good time; and there is every chance of good success attending the operation, with a great variety of kinds, should the ensuing winter prove mild and moist; but if it be severe, and the frosts prolonged, many kinds of newly planted trees are likely to suffer and die, particularly if planting has been delayed till about the end of November or later, as by that time the ground is too cold to promote root action, and the trees, consequently, have no chance of getting partially established before winter is upon them; and if they happen to be much cut and mutilated at the root they are in a still worse plight, being then in little better condition than a cut branch inserted in the ground. Trees that are moved with good balls of earth to their roots are generally safe, even in severe winters; but good balls and plenty of roots cannot be secured in some cases. On the other hand, it is urged against spring planting that, should the summer prove warm and dry, the trees are just as likely to suffer from these causes, unless they can be abundantly supplied with water, which, of course, entails a great amount of labour. Probably the advantages of transplanting in autumn and spring are about equal in the case of evergreens, while deciduous trees have the best chance when moved in autumn—just when the leaves are about to fall; and this being so, of course those trees which shed their leaves first should be first dealt with. Some recommend September as the best month for autumn operations in the case of evergreens; and perhaps it is, in a general way, as by that time the current season's growth is tolerably hard and mature, and not so likely to shrivel. October is also a good month, but later it is not safe to wait. What cannot be done before November had better be left till the following spring. We have transplanted trees and shrubs every month in the year, when compelled by circumstances to do so; and, judging from experience so gained, we have come to the conclusion that the most favourable times are September and October in autumn, and from the middle of March till the middle of May in spring; but the latter

dates apply to the north more particularly. In the south, operations might probably be begun and end a fortnight sooner.

During the past few years we have noted the effects of transplanting at different periods upon a great many trees and shrubs. Hollies, Yews, Deodars, and Laurels, &c., transplanted from the beginning of December till the end of January, when the weather was favourable, just succeeded according to the size and entirety of the ball of soil secured with the roots. The ground in many places being shallow and stony, it was next to impossible to get balls, and in all such instances the trees have suffered by removal, and some have died outright, especially Hollies and Laurels of large size. Very few deaths—only one, I think—have, however, occurred amongst the trees moved in September and October; but in all cases the spring plantations have done the best. Of a number of large Hollies and Yews, between twenty and thirty years of age—some of them not with very good roots—not one has been lost, nor have they ever shed their leaves to any great extent. All made growth, and some Hollies moved near the end of May made young shoots 6 in. long the same season. The same kinds of evergreen trees and bushes, transplanted just before and after midsummer when in full growth, have all succeeded; but Laurels, Rhododendrons, and Hollies lost their young shoots, which, being soft, withered and turned black. Notwithstanding possible injury from heat and drought, we would much rather risk transplanting at midsummer than at midwinter. Heat and drought are easier withstood than frost or prolonged cold. But, as we have said before, much depends upon the kind of subject dealt with. Trees or shrubs that produce abundance of roots in a compact form may be transplanted almost at any season, as good balls can always be got with them. The Box tree, for example, has such a multitude of roots, and all held together in such a mass, that it is hardly ever affected by removal, no matter what season of the year it may be. It is the same with the Rhododendron, and also with the Aucuba, and a good many other close-habited subjects, the roots of which mostly correspond to the habit of the branches. C.

AUTUMN-TINTED TREES AND SHRUBS.

A VISIT just now to the extensive nurseries of Mr. Anthony Waterer, Knap Hill, Woking, is well repaid, if only to see the resplendent coloration of the various deciduous kinds of trees and shrubs there in their autumnal livery. The gorgeous hues of the decaying foliage of the Western Azalea (*A. occidentalis*) are very striking. This Azalea is comparatively little known in this country, but it is plentiful in, and a great ornament to, the wooded districts of California. The leaves are oblong or lance-shaped, and have a tendency to be clustered at the upper parts of the branches. They vary in colour from a pale red to the richest deep crimson, and they are sometimes laced with a golden tint, altogether rendering them most attractive, more particularly when seen in masses. The leaves, before they change colour, are a bright shining green, and form a fine setting for the large fragrant white and sometimes rosy blossoms, each of which have golden bands. Another strikingly beautiful variety is Graf Von Moran, a kind in the way of *A. narcissiflora*. This was much admired last spring at South Kensington, where it was deservedly awarded a first-class certificate. Its leaves are considerably broader than those of the foregoing, but scarcely less brilliant; and large bushes of it have a striking effect when seen in company with the ordinary forms of the Ghent Azaleas, which, unfortunately, do not take on such a rich autumn garb. Other Ericaceous plants, such as *Vacciniums*, &c., have beautifully-tinted decaying foliage. Amongst these the Pennsylvanian Whortleberry (*V. pennsylvanicum*) is especially noteworthy. It is a much-branched under shrub, growing about 3 ft., high, with leaves of the deepest crimson. Like its congeners it is a peat-loving plant, but thrives well under ordinary conditions.

Turning to the larger-growing subjects which have attractive autumn foliage, there are few more beautiful than the yellow *Virgilia* (*V. lutea*), a North American tree, which grows here to a great size. The many trees about the nursery are conspicuous from every part by the bright golden hues of the foliage. It is, besides this, a most desirable tree for general planting, and certainly deserves to be better known than it is. Many of the Maples are very prominent in this way, especially *Acer ginnala*, with its splendid glowing ruby tints. *A. dasycarpum*, or as some call it, *A. eriocarpum*, is very attractive too; its leaves assume a rich golden hue, which, with the handsomely cut and silvery under-surfaces of the leaves, renders this tree a fine object. It is considered to be desirable, if not preferable, to the Western or true London Plane for town planting, and has been successfully tried in some of the American cities. The beauty of the foliage of the various kinds of *Rhus*, especially in autumn, when it assumes the richest colours, renders them worthy of a place in every garden. Here several of the species form a very conspicuous feature, as do also the splendid examples of the Weeping Beech, the largest of which is a noble specimen, and probably the finest in

cultivation. The numbers of smaller examples about the nursery also add to the display, together with the purple varieties of Beech and Birch. Than the Japanese Maples—varieties of *Acer polymorphum*, &c.—it would be difficult to name a class of more elegant shrubs, and it is much to be regretted that they cannot be termed hardy generally. The plants at Knap Hill in the open air are wearing splendid tints, from coppery-red to golden-yellow, the effect of which is enhanced in many of the varieties by the delicate feathery foliage. Near to these is what may be considered one of the sights of Knap Hill just now; it is a species of Vine, with leaves well-nigh 1 ft. square and tinged with golden and crimson hues, towering amongst the sombre green foliage of lofty Conifers, the appearance of which thus clad may be better imagined than described. This kind of effect is apparently cultivated by Mr. Waterer, for a similar instance occurs close by in the form of the well-known *Wistaria sinensis*, not trained to a wall or trellis, as is usually seen, but twining itself from the trunks to the very tops of some trees of *Pinus ponderosa*, *Abies Douglasi*, &c., 50 ft. to 70 ft. high or more. In this position it is never injured by frost. These remarks apply only to the more prominent features of the nursery at the present time, and are, of course, by no means exhaustive even on the subject of autumn-tinted trees; these, in conjunction with the vast collections of hardy trees and shrubs, and more particularly the *Rhododendrons* and the unique collections of *Yews*, *Hollies*, &c., which are spread over a great extent, constitute an autumnal picture which could rarely be met with elsewhere. To those who are contemplating planting the present season is one of the best to visit a tree and shrub nursery like this, for not only is there the advantage of seeing the effect of certain subjects in autumn, but also the condition in which they are previous to transplanting.

W. G.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Dwarf Furze (*Ulex nanus*).—When passing recently over a track of wild unreclaimed land I was much impressed by the beauty of this dwarf species of Furze. It is a rather local kind, though growing abundantly where it occurs. Its foliage is much finer than that of the common Furze, and the plant altogether is of much smaller proportions, rarely exceeding 18 in. in height, and in many instances forming compact little tufts not 1 ft. in height, and studded with bloom. During the dull months of the year it presents a very cheerful appearance. It might be usefully employed in the wild garden, or in the half-dressed portions of the pleasure grounds. It would also be an excellent subject for covering sloping banks, or for planting in poor, stony, or sandy soil, where the generality of flowering plants would refuse to thrive. In a mild season it will continue gay throughout the winter, but in a general way it is most effective during the late autumn, early winter, and early spring months.—J. C. B.

Escallonia macrantha.—On the platform at Battle Station there is a magnificent specimen of this *Escallonia*. It is 20 ft. in circumference and 7 ft. high, and is loaded with coral-coloured bunches of flowers. The beautiful dark green, fresh looking foliage of this plant should recommend it to all who are near the sea coast. It is equally well adapted for covering walls, rocks, &c., and for hedges and single specimens.—T. S. W.

Lycasteria formosa.—I agree with Mr. Cornhill (p. 362) that this old-fashioned shrub is well worth more prominence than has hitherto been accorded it. With us some single bushes of it on Grass, sheltered by Conifers, withstood the last severe winter without any protection, but it deserves a little extra care, as it is highly ornamental for a long period. Doubtless the desire for brilliant colours helped to thrust it into the background, but now when that is subsiding we may reasonably hope that plants of this kind will again be sought after and receive the attention which they deserve.—J. GROOM, *Linton*.

An Irish M. P. on Planting.—At a meeting held in the early part of this week in the county Leitrim, speaking of the reclamation and improvement of waste lands, Mr. P. J. Smyth, M. P. for Westmeath, said that there were in Ireland some 4,000,000 acres of waste land, not one acre of which could be said to be absolutely irreclaimable. It is, he said, admitted that fully one-half of the 4,000,000 acres are profitably reclaimable in the sense of the capitalist or the speculator, but every acre of it is profitably reclaimable in the sense of the enduring prosperity of the country. The bleakest mountain side, the worn-out bog, will produce timber, and an abundance of timber in Ireland would give it a new climate, new industries, and a higher civilisation. The surest way to barbarise a country was to denude it of timber. They found invariably

that in well-wooded countries the inventive faculties of the people were stimulated, various industries were followed, the arts grew, and civilisation made a home.

THE LIBRARY.

NOTES ON LILIES*.

THE Lily, like the Rose, is pre-eminently an English garden flower, and one which has been the cherished inmate of old abbey and manse gardens for many centuries. Side by side these two flowers have struggled on through the changing tides of many fashions, supplying lovely imagery to English writers on theology and other subjects, as well as to skilled workers in wood and stone. Chaucer and Herrick, Shakespeare and Milton, alike fixed various phases of Lily beauty in our language just as the fair workers in tapestry, and the religious forefathers of Gibbons and Chantry foreshadowed its loveliness in textile fabrics and in tree or rock. There is a subtle charm about the older, or rather longest known of Lilies, which it is difficult for one of unpoetic feeling to express aright, and we scarcely can believe in all its suggestive fulness that the White Lily of to-day is the White Lily of Chaucer's "Canterbury Tales," and the one on which people of many tongues have gazed. Being a native of southern Europe, it has been assumed that bulbs of it were brought to our gardens by the early Crusaders, and it is as a part of armorial bearings that Chaucer notices it in his lines—

"Upon his crest he bare a tour
And therein stiked a Lily flour."

That the Romans of old, who were the best gardeners of their time, admired Lilies we may gather from Columella, who tells us that, planted in baskets of earth, their flowers and verdure are long preserved. Pliny's notice of it as being second only to the Rose is a matter of history, and the Greeks of to-day place wreaths of Lilies and corn on the heads of their brides. Queen Elizabeth must often have gazed on the "filled up glory" of the White Lily since Gerard says of it "our White Lillie groweth in most gardens," and old Parkinson also wrote of and figured it as early as 1629. This Lily seems to have been an everybody's flower in those days, since he thus speaks of it: "The ordinary White Lily scarce needeth any description, it is so well known and so frequent in every garden," adding that it "groweth only in gardens and it hath not been declared where it is found wilde by any that I can hear of." Again he observes that the flowers of it are many or few "according to the age of the plant, fertility of the soil, and time of standing where it groweth," nor does he forget to tell us that "it flowers in June or thereabouts, but shoots forth green leaves in autumn, which abide green all the winter, the stalk springing up between the lower leaves in the spring." Of *L. bulbiferum*, Parkinson tells us that "this Lily will shoot strings under ground like as the gold red Lily will also do, whereat will grow white-bulbed roots like the roots of the mother plant, thereby quickly encreasing itself"; and of the "greater bulbed red Lily" he says that "this is more plentiful in bulbs and in shooting strings to encrease roots under ground than the others." Of *L. canadense* the same careful old author states that it was brought into France from Canada by a French Colonie, and from thence unto us; "while of the whorl-leaved *Martagons* he says that "all these Lilies have been found in the divers countries of Germany, as Austria, Hungaria, Pannonia, Stiria, &c., and are made denizens of our London gardens, where they flourish as in their own natural places."

Until about some ten or perhaps some fifteen years ago Lilies were quite common flowers in cottage gardens nearly everywhere. I well remember a little pastoral hamlet in the Midlands, where two irregular rows of thatched or red-tiled cottages stretched on either side of the long street. The walls were white-washed, and each cottage had a patch of flower garden in front, and long, narrow, wall-girt strips of vegetable ground stretched towards the meadows and Fir plantations behind. In the little front gardens Lilies were rampant, and I have never seen such perfect sheaves of tall flower-stems anywhere since that time. The kinds were the common white, the scarlet Turk's-eap or Turban, the Orange Lily, and the *Martagon*, both purple and white. Other flowers in plenty were the *Narcissus*, *Crocus*, *Snowdrop*, and *Crown Imperial* in enormous patches, followed by *Pinks*, *Carnations*, and *Sweet Williams*; but the glory of the village gardens was at its height in June when the snowy Lilies were in bloom. Year after year up came the leafy wands, seemingly stronger, taller, and more beautiful than before, and the only care they ever received was an annual top-dressing of manure during the winter. This much care was due to the advice

* "Notes on Lilies," 2nd Edition, by Dr. Wallace, Colchester, 1879. New Plan and Bulb Company.

of an octagenarian, John Dale, the knee-breeched old gardener at the hall, who used to gather around him an admiring audience of cottage gardeners one or two nights a week in the snug back parlour of the "Rose and Crown." He always found the best armchair by the old-fashioned chimney nook awaiting him, and his weather lore and knowledge of "the crops," as imparted "staccato" between whiffs at a churchwarden or yard-long pipe, were always listened to with respect. I have heard him discoursing on Lilies myself, and this, as far as I can remember (for it is now over twenty years ago) was his style:—"Lilies is Lilies you see," said old Dale, "and if you don't mind them in winter and spring they'll be frost-bit! They be like 'taters be they roots, you takes up your taters an' leaves down your Lilies; and so if you don't keep their toes warm they'll rot!" Therefore the Lilies were duly protected by a covering of manure in the winter; they were never disturbed, as Nature's Lilies are never transplanted, and they didn't "rot," but they throve apace rather, and made a common-place village beautiful to see for at least three months out of the twelve. "Some folks uses ashes, but muck is best" said Dale, "'cos it feeds 'em as well as keeps 'em warm you see, just like a top-coat." The Lilies in question were the *feu de joie*, but Roses and many other hardy flowers kept up a running fire all the year round. How long these Lilies had been thus generally grown no one seemed able to say. The forefathers of some residents in the place had held tenure for three centuries at least, and the Lilies may also have existed nearly equally long, since all those hitherto named (and even *L. canadense*) were well known over two centuries ago. When, however, the rage for "bedding plants" had fairly set in, the Lilies lost their places first in large gardens, and then the new fashion—geometry in blue, red, and yellow lines, spread even to the old cottage gardens in front of the neat white walled cottages in some of the most sequestered country hamlets. Men of old Dale's stamp, with a genuine love for Lilies and all hardy flowers, died out; and younger men favoured the craze of their time until our "flower gardens" looked like a collection of the "flags of all nations," and we were reminded of the confectioner's decorations on a wedding cake, or, as Bacon puts it, we had seen such things "on tarts." Thousands of Lily bulbs were swept away by the new fashion, and yet there were some kinds strong enough in constitution to hold their own even in starved shrubberies, to which they had been removed to make room for the "ribbon border;" and in some few places—as Bitton, for example—they were welcomed, sheltered, and wellfed, exiles though they were. There were some cottagers in secluded districts who also spared them, but it has been left for us to grow and enjoy Lilies in a fulness perhaps unenjoyed by any one people of bygone days. The dark ages of English flower gardening are past, and every lovely flower has now its meed of praise, its share of somebody's admiration and care. The queenly Lily is one of the first of favourites; in the gentle tournaments of to-day she has her place in every garden, and even "Our Lady" places her name on the title page of the magnificent folio volume of plates so recently devoted to the portraiture of the Lily Queen by Mr. Elwes.

What we have said of Lilies is also true of Narcissi and other bulbous plants, and we owe our best thanks to Dr. Wallace for having in the book now before us brought together to a focus as it were not only his own bright light on the subject, but the light of the most successful of nearly all other Lily growers as well; not only is the nomenclature and classification of Lilies made easy for us by Mr. Baker's synopsis as herein reproduced, but there are valuable letters from many who have seen the Lilies of Europe, California, Japan, and the Himalayas growing wild. The native conditions under which Lilies are found are clearly set forth, as is also the experience of the most successful of Lily growers in England, Ireland, and Scotland. Special examples of culture are quoted, and the letters of foreign botanists and collectors are supplemented by notes on hybridisation, propagation, and the details of Lily culture in pots as well as in the open air. Dr. Wallace has himself imported many thousands of Lily bulbs from all habitats; hence we need not be surprised to find that he has given all due prominence to the underground or bulb growth of Lilies, as set forth for the first time by engravings and descriptions in our columns some years ago. Scarcely a point of interest likely to occur to the humblest of Lily cultivators has escaped notice; thus, in the notes on propagation, we find that Lilies are increased by seeds, cuttings, layers, offsets, or bulb-bearing stolons, and by planting the scales of the bulb either attached to a bit of its axis or not, as the case may be. We are told that—as in the case of Irises and Narcissi—the Lily may be grown in the open air up to its flowering stage, and then transferred to a pot for portability or indoor decoration. That there are little oversights and misprints, no one, perhaps, is better aware than the author himself; and we ourselves venture to supplement the information about cut flowers by pointing out that Lily flowers, if wanted for indoor deco-

orative purposes at a distance, are best cut just when their flower-buds are bursting, or even a few hours before, rather than after expansion. Thus cut, each bud, wrapped in silver paper, travels safely and in a smaller space than in any other way. When Nature unpacks her Lily buds it is impossible to pack them half as well again. On arriving at their destination, if the buds be taken out and placed in warm water (120° Fahr.) and in a warm room, each flower will quickly expand in all its pristine freshness; there will be no bent or bruised petals, and no smearing of pollen on the flowers. This is equally true of Water Lilies, Gloxinias, Irises, Gladioli, and Narcissi, and a knowledge of these facts is worth many pounds per annum to gardeners and florists who have to pack loose and tender-petalled flowers for travelling long distances.

The care necessary to grow Lilies well in pots is clearly pointed out, and what not to do is tersely expressed. Thus we are told that bulbs and plants are liable to be dried up and starved from want of nutriment in pots both summer and winter; and the extreme danger of "drying off," or neglecting to water pot Lilies during the winter months is also alluded to. The fact that outdoor Lilies get much more water during winter when without leaves, than in summer when growing freely, is not so forcibly expressed as we could wish, however, and the statement which is quoted on p. 13 "that the bulbs [in pots] undergo a resting period, and comparative dryness in winter" must be looked upon as in some degree misleading in itself as it stands. We have long entertained, and have elsewhere expressed, the idea that bulb growth may be much strengthened by sacrificing the flowers for a season, and this point is also alluded to and its advantages pointed out in one or two places. By breaking off the top of the flower stem just before the flower buds form, we throw all the vigour of the leaves, much of which would ordinarily have gone to build up the flower tissues, into the bulbs to their manifest advantage. This is a point proved beyond all doubt. In the case of pot Lilies, more especially, the application of manure water or manurial top-dressings seems essential just as the secondary or stem-roots appear in whorls on the stems above the surface of the soil. By feeding these secondary roots thus, any extra drain upon the old bulbs is prevented, and they are enabled to build up that new bulb growth or "change of centre" so essential for the security of the next year's bloom. We have been told that "no bulb blooms twice"; the fact is, however, that no bulb blooms from the same centre of growth twice, but the same bulb may for years go on increasing its axis and changing its centre or growing point from which other flower-stems may arise. In the North American Lilies of the *L. pardalinum* group, this fact is most clearly evident, but all Lilies are alike in plan, the difference being in degree.

In the instance of the common white Lily, Mr. Frank Miles' plan of circumventing slugs (see p. 45-46), by separating and replanting too crowded clumps in lime-dressed soil, is a very good one, and his advice on repotting Lily bulbs in autumn is too valuable to be here passed by. "People make a great mistake in repotting their Lilies in spring when the soil is full of new roots, instead of in the autumn when there is nothing but old roots in the pots." Mr. Miles also, on p. 47, alludes to the fact of bulb growth being improved by breaking off the flower-buds when just formed. It is clearly pointed out (see pp. 53-54) that Lily bulbs are not resting during the winter, but actually forming roots or underground growth. Here then we see why Lilies must never be "dried off" in winter, either artificially or by allowing moisture-licking frosts to suck the ground dry above or around them. Thus it is apparent that Lily growth is of two kinds, each kind dependent on the other—firstly, above ground, leafy stems or flowering growth during summer; and, secondly, subterranean bulb growth during winter; and it is the latter kind of growth that is in most danger of being ill-treated, unwittingly it may be, since being buried, it is, as a rule, unobserved. If bulbs are planted in Rhododendron beds or shrubbery borders, one must of necessity see that the earth is well enriched, shrubbery borders being, as a rule, sucked dry by the hungry roots of the bushes and trees therein arranged. If planted in open beds or borders, then carpet the soil with surface-rooting Veronicas, Sedums, Saxifrages, or even Mignonette, and other annuals rather than allow a barren evaporating surface to exist. If the soil is too heavy or close, use turf ashes or a load or two of gravel or sandstone broken into small nodules. To use fine white sand is worse than useless in such cases, and too expensive withal. In hot, dry soils stones as big as one's fist, or even larger, are valuable for condensing and retaining moisture, which otherwise would evaporate from the surface. In the case of the noble *L. giganteum*, a deep border of peat earth, loam, and nodules of sandstone suits it exactly; in ordinary, well-drained Rhododendron beds it succeeds also to perfection, but of all conditions I find that shelter is indispensable, and in a shady spot this Lily seems most at home. There is much valuable information respecting all the Lilies in the book before us, to which we must refer the reader. In conclusion we heartily congratulate

Dr. Wallace on having reproduced a handy work on Lilies, which is much wanted. B.

SOCIETIES AND EXHIBITIONS.

POMOLOGISTS IN COUNCIL.

By W. H. COLEMAN.

THE seventeenth biennial session of the American Pomological Society was held at Rochester, N.Y., Sept. 17th to 19th. Pomologists from Missouri to Nova Scotia were present. Dr. John A. Warder, of Ohio, presided. The venerable Marshall P. Wilder, President of the Society during thirty-two of the thirty-four years of its existence, was unable to be present by reason of advanced age (he is eighty-four) and suffering from the effects of an accident, and sent his resignation, embodied in an address which, for its pathos and beauty, thorough review of the past work of the Society, and wise counsel for the future, was a remarkable paper to come from one so enfeebled. He was, however, unanimously re-elected, the Society deeming his name worth more than the living presence of any other man. Financially, the Society is in good form. The income has been about 1,200 dollars, the expenditure 900 dollars. The chief expense is for the issue of a full report of the fruit discussions and the work of the State committee in revising the lists of fruits adapted to the various parts of the country.

The exhibition was held on the fair-ground, two miles from the City, in connection with the Western New York Fair. A large tent was well filled with collections of fruit from Massachusetts, New York, Ohio, Michigan, Iowa, Missouri, and Nova Scotia. The latter two were near each other, and proved an interesting comparative study. Varieties that were green and hard in the northern collection were over-ripe in the western, and there was said to be a difference of two months between them. There were in all 1,835 plates of fruits.

The chief interest centred about the new Grapes, especially the white ones, of which never before has there been such a varied and excellent show. The largest display was made of the Niagara and the Prentiss. The former originated with Mr. Hoag, of Lockport; is a Concord seedling, the Vine a very strong grower and abundant bearer, the Grape large in bunch and berry, cluster long and rather loose, flesh juicy and nearly tender, quality good. It promises to be hardier than most white Grapes, and, like its parent, to be adapted to general cultivation. The Prentiss originated with Mr. Prentiss, of Crooked Lake, and has been fruited for ten years. Mr. Prentiss has an acre of it in bearing. In growth and habit the Vine is like that of Roger's hybrids. The fruit is smaller than that of the Niagara, bunch more compact, quality better, resembles Rebecca in taste, and if hardy everywhere, will prove a fine substitute for that excellent Grape. The Duchess originated with Mr. Caywood, and was shown by him, and also by Messrs. Farley and Anderson, Union Springs, N.Y. It is a seedling of the Montgomery, bunch and berry of good size, between the Prentiss and the Niagara, quality excellent, though the specimens were not quite ripe. Mr. Ricketts, of Newburg, N.Y., had several of his newer seedlings; amongst them were Lady Washington, a white Grape, the largest in size of bunch on exhibition and of fine quality; the Naomi, also white, fine in appearance and of a delicate rose flavour; and Bacchus, a small-berried black Grape, said to be a good wine Grape. Mr. Barrow exhibited the Jefferson (a Ricketts seedling), a rose-coloured Grape of Iowa flavour. The Poeklington, a white Grape, has been shown several years; it is a Concord seedling of very large size, sweet, but coarse in quality. Fine samples of the Brighton were shown. This is now the popular red Grape. It is not quite equal to Catawba in flavour, but it is so good and ripens so surely by the 1st of September that the latter can be easily spared where the lateness of the season prevents its ripening. The Lady, now before the public for several years, a Concord seedling, is very early, of good size, sweet, but musky in flavour. The Vine is a slow grower at first, but does better as it gets older. Moore's Early is a very large, showy, black Grape, of ordinary quality, valuable in Massachusetts, where the choicer Grapes do not ripen well. Mr. Isador Bush, of Missouri, showed the Elvira and Noah, white Grapes of the Riparian class, which make excellent wine in Missouri. (In Geneva, N.Y., the Elvira proves a very strong grower and prolific bearer—a three-year transplanted Vine setting thirty bunches the first season and one hundred the next. It ripens rather late, however, and is only fair in quality. The bunches are small). Mr. Roe, of Cornwall, N.Y., showed a basket of fruit from a Concord sport. A certain branch of a Concord Vine bore larger, juicier fruit than the rest. This wood was taken and propagated, and the new Vines bear fruit like that of the original cane. The bunch in shape is like the Rogers, berries very large, very juicy, and of distinctively Concord character, adhere well to the stem, and do not crack. It seems to be an improved Worden, which

has been called an improved Concord. Some unnamed hybrid seedlings from Dr. Culbert, of Newburg, N.Y., were of delicious quality.

Mr. Ricketts exhibited a new Peach, the Mrs. Brett, which was remarkable for size and colour. It is white-fleshed and delicious in flavour. Messrs. Ellwanger & Barry had some Souvenir du Congrès Peaches of such enormous size and enticingness that for safety they were kept in a wire cage. Some Fillbasket and Stump Apples were remarkable for their size and colour. A little 2-in. fruit, shaped like a Bartlett Pear, was labelled, "This is an Apple."

Among the regular addresses the most noticeable were those by Mr. Thomas Meehan and Prof. W. J. Beals. Mr. Meehan spoke on the apparent waste of blossom and pollen (as in the Chestnut tree, which produces thousands more than are needed to perfect the actual fruit), believing it to be a provision for insect life, and teaching the lesson that even Nature is unselfish, and her subjects work for others as well as themselves. He also explained the use of sex in vegetation to be the reproduction, not of individuals, but of varieties. Prof. Beals gave an account of the studies of Apple blossoms and his proposed method of recognising the different varieties of Apples by the difference in the petals and other parts. This was illustrated by large drawings, and excited much interest.

The discussions comprised new Grapes, Peaches, Raspberries, and Strawberries. In the talk on Grapes, Moore's Early was praised by the Massachusetts men as two weeks earlier than the Concord, but elsewhere it was not in favour; the Cottage is inferior in flavour and drops from the stem; the Worden was two weeks earlier than Concord with Mr. Willard of Geneva, one week with Mr. Campbell of Ohio, no difference with Mr. Craine of Lockport; the Niagara is earlier than Concord and good in foliage with Mr. Moody of Lockport, remarkable for size of cluster with Mr. Craine, and Mr. Younglove, of Vine Valley, had seen clusters on the Vine one month after ripening; the Brighton blights and does not grow with Mr. Saul of Washington, is excellent and healthy with Mr. Hubbard of Fredonia, succeeds as well as Rogers with Mr. Strong of Massachusetts; the Prentiss, with Mr. Hubbard, is a good grower, ripens with Concord, quality excellent, never cracks, good keeper; Mr. Younglove had seen the Vineyard, habit of growth was like Emmelah; Lady Washington was healthy in foliage with Mr. Campbell, but had not fruited yet. Mr. J. W. Manning had seen it at Mr. Ricketts's, fine, strong Vine and clusters; Early Dawn mildews at Newburg; the Lady does well with Mr. Saul, and is two weeks earlier than Concord, is best white Grape with Mr. Auger of Connecticut, is earliest with Mr. Strong of Massachusetts, is early, good, and healthy with Mr. Hubbard, but not a strong grower. Dr. Beadle, of Ontario, said the Champion was being sold in Canada under the name of Beaconsfield. Dr. Hamilton, of Nova Scotia, said they could grow good fruit there, as the exhibition showed, and he had even succeeded in ripening the Black Hamburg out-of-doors.

In the talk on Peaches, Alexander and Amsden were pronounced to be identical; Mr. Purdy, of Palmyra, N.Y., called the Waterloo the finest of early Peaches; Mr. Hope, of Georgia, found the Wilder a week later than the Downing; Mr. Saul praised the Bower's Early and Levy's Late; Mr. Newlin, of Arkansas, mentioned the Gov. Garland; Mr. Husmann commended the October Beauty, a Missouri seedling, as a fine late Peach; Mr. Van Dusen, of Geneva, spoke of the Dunlap as a favourite in Seneca County, and coming true from the stone. In the talk on Strawberries, Mr. Barry praised the Sharpless for size, quality, and bearing; Mr. Roe found Crystal City the earliest, Golden Defiance the latest, and Charles Downing one of the best; Triple Crown is a fine late, Newman's Prolific does well at the south, Miner's Prolific is one of the most promising, Duchesse best early, Duncan soft at home but firm at the south, Crescent Seedling immense bearer, but of common quality; Mr. Wm. Barry said Cinderella bore a large crop of perfumed fruit, Continental was a profuse bearer, but of poor quality; Mr. Purdy found Pioneer early and beautiful, Windsor Chief most productive, Cumberland Triumph very handsome, Endicott fails here but succeeds at Chicago; Sterling of no value, Newman poor in every way, Marion leathery but a good shipper; Mr. Husmann, of Missouri, liked Captain Jack for market and Cumberland Triumph for home use, Charles Downing and Kentucky both good; Mr. Bush liked Crystal City; Mr. Lynn, of Michigan, praised the new seedling Marion.

The society was entertained in the evening of the 18th in Power's Art Rooms. A supper was served, with appropriate toasts and speeches. The tables were adorned with a display of fruits and flowers such as even Rochester had never seen before, and pronounced unequalled by those who had attended previous banquets of the kind.

The ground in front of the Great Northern Railway terminus, King's Cross, is about to be laid out as a garden.

CALIFORNIAN NOTES.

Liliorhiza lanceolata is among the earliest of our spring blooming bulbs, with a habit and appearance slightly similar to the spring Snowdrop, which is so much prized in the eastern states. Its flower stem, which has but few leaves, is from 6 in. to 15 in. high; the scattered leaves run into bracts near the summit, from whose axils spring the flowers, which at first appear to project outward, but gradually droop with age. I have rarely seen eight flowers in the raceme, the last blooming as the first fades. The six leaves of the perianth, which are white with green veins, at first form a cup about as deep as wide, sometimes $1\frac{1}{2}$ in. each way, but as the flower ages the tips turn back and form a bell-shaped blossom with a reflexed margin. The odour is rather unpleasant to some. The blooming bulbs often grow at a depth of 1 ft. or more in stiff *adobe*, and as the bulbs are composed of several loosely coherent scales, it is often very difficult to obtain them entire. The bulbs are a clear waxy white, and sometimes attain a diameter of 1 in. and $1\frac{1}{2}$ in.

The *White Camassia* is nearly related to the blue *Camassia esculenta*; it grows often on open sandy ridge tops, but is also found in dry spots in shady ravines; its bulbs are generally deep in the ground, the base in some stiff moisture-retaining soil, so that the base of the bulb is often injured in digging. They are often 5 in. long by 2 in. in diameter. In lighter soils the spike of bloom is large, often containing upwards of 100 florets, and being 9 in. long by 4 in. in diameter; while in heavier soils the spike is sometimes compounded, and contains several hundred florets, which are white, and about $\frac{1}{2}$ in. in diameter. The spike often reaches 3 ft. or 4 ft. in height. The cluster of leaves from the bulb often reaches 18 in. in height, each leaf being about 1 in. across.

Lilies and Pansies.—In small gardens the all-important question is how to save space and obtain the greatest enjoyment from every inch of the surface. While enjoying our beds of Japan Lilies this summer, it has occurred to us that since some of them, particularly the auratum, do not like over much sun, and all of them hate too frequent removals, it might be possible to scatter them among surface-rooted flowers, so as to save space, and ensure an attraction for more months of the year. For this purpose we think that it would only be necessary to plant Japan Lilies rather deeply in well prepared somewhat shaded beds, and then place a sufficient number of small Pansy plants on the surface to give the bed a reasonable excuse for existence.

Abronia Without Water.—The common Beach *Abronia umbellata* cannot be praised too highly as an autumn bloomer without any water whatever. A circular bed is one of the brightest things in a garden, and once fairly rooted, it ought to be permanent. Long branches are useful for decoration, if used with plenty of white.

Catalonian Jasmine.—This, through the summer and autumn, is the best fragrant, white-flowered climber we know of. Ours has made a large growth this year, and is a mass of white sprays and clusters. It does not seem to thrive in a pot, but as soon as planted in the open air it flourishes exceedingly, and is the admired of all beholders. This Jasmine is not the sort of plant to make a great shelter within a brief time. It is fragrant and delicate, has a cultivated, gracious air, and is altogether charming.

Californian Bananas.—Much has been said this summer of the dwarf Cavendish Banana, and immense clusters of the fruits were on exhibition at the recent State Fair, and at several District Fairs this season. In some cases the fruit was ripe, but it was not of a clear rich colour, or of high flavour. This has discouraged some growers who had hoped to be able to produce an article fit for market, and of sufficiently good quality to drive imported fruits out of the market. But we do not consider that the Banana has yet had a fair showing on account of the severe and unusual cold of last winter.

Water as a Protection Against Frost.—Now we have always been taught that irrigation of the trees in autumn and winter is very injurious, and should never be resorted to. Alas! for the theorists; those of my neighbours who followed their advice last winter lost heaviest. Myself and a friend of mine, Mr. MacNiel, had better luck, and I will now shortly tell you how it was. Last summer I had planted a large circle in front of the wine cellar with rather tender trees, such as *Araucarias*, &c., which generally are supposed to be unable to withstand our winter climate. Not knowing any better, of course, I kept the water away from the trees from the 1st of October, and the ground got well dried up. As you know, we had very severe frosts about Christmas time, and the trees had been left uncovered. The day before the heavy frost there was a large break in our irrigation ditch near by. The water flowed down, and, to my great dismay, covered a part of a circle where I

had my tender trees. Of course I thought they were all gone. The water standing round the trees froze solid, and just as far as the water had reached the trees were saved. The irrigated ground kept moist the whole winter, and after every frost presented the appearance of a heavily frozen surface. One day in the early spring I visited Mr. MacNiel and incidentally told him of my experience. "Why," he said, "that is just mine too, come along and you will judge for yourself." And so we went out through the Peach and Almond orchard, one mile and a half or so, down to the Orange trees. Last fall Mr. MacNiel had 800 Orange and Lime trees alive, all budded, and about five years old. Now there were only 250 left alive. "Well," said my friend, "a day or so before the heavy frost, the boys on Chapman's forty acres took a notion to irrigate their sheep-pasture, and did not care a bit for the big break in their ditch. Accordingly I found, to my great vexation, half of my Orange trees flooded next morning. The water had run here and there in the lowest places, of course, and, look here, you may see it plainly, wherever the water did go, there the trees are alive. The dry places were occupied by trees which you now see dead to the roots." And indeed my friend was right, the water had saved our trees, no mistake about that.—*Californian Horticulturist*.

ANSWERS TO CORRESPONDENTS.

Double White Rocket.—If "An Old Gardener" (p. 367) will write to Wm. Wardle, of Winsthill, near Burton-on-Trent, I have no doubt that he will inform him where he can procure the old dwarf double white Rocket. I have but one solitary plant, and consider it, when well grown, second to none of the other three varieties. The two giant double Rockets, when strong, are somewhat coarse, which the dwarf double white certainly is not. Mr. Wardle's plants came from Ireland.—WM. ELLIOTT, *Stocksbridge*.

Rose Hedges.—Can any one tell me from his own experience of a good Rose for forming a Rose hedge to enclose one side of a Rosery.—T. E. C. (Hybrid Chinas: Charles Lawson (rose), Coupe d'Hebe (pink), Madame Plantier (white); Hybrid Perpetuals: Anna Alexieff (rose), Magna Charta (pink), Maréchal Vaillant (red). Any one of these would make a good hedge of Roses.—W. P.]

Worn-out Lawns.—How can I improve a lawn which seems to be almost worn out?—P. (In March next scarify the bare patches with a sharp-toothed iron rake. Apply a rich top-dressing of fine soil, and sow Grass seeds thickly, raking them well in, and rolling the surface smooth and even. If the Grass needs more encouragement apply soot, or any artificial manure that contains a good deal of ammonia. There has been so much mowing this season that the Grass needs extra support.—H.]

Propagating Clematises.—J. B.—Clematises are propagated by grafting them on the roots of common kinds, or by layers, or by division of the roots. To obtain young plants by layers the wood as it grows should be pegged down at each joint, a small cut being made close to the bud with a sharp knife to induce roots to be thrown out. Some fine sand should be mixed with the soil in order to induce free rooting. Stop the growth of the main shoot after several joints have been so layered, and when rooted the wood can be severed and the young plants lifted. Old roots may also be lifted in the winter, and be carefully divided.—D.

Champion Potatoes.—Do these do well in what are called lazy drills, or is it better to plant them in ground that has been broken up? I am thinking of planting some when the time comes; the ground I am going to put them in is now Grass. If they do not do well in the lazy drills, I will have to rake the ground up.—SUBSCRIBER.

Wintering Echeverias.—Alpha.—*E. secunda* and *secunda glauca* may be wintered freely in the open air if banks of soil be built up against a wall or greenhouse or other building, with a very steep slope. Into these banks the *Echeverias* should be planted thickly, and no harm will result to them until very severe frost comes, when some mats, sacks, or other coverings placed over them will keep them safe. The sloping position throws off wet, and thus frost does less harm.

Neglected Asparagus Beds.—I have just taken possession of an old garden in which the Asparagus beds have been much neglected. How can I improve them?—W. (When the tops are ripe (which may be known by change of colour), dress the beds with salt, 7 lb. to the square yard, and place all over the surface of the bed 5 in. or 6 in. in thickness of good manure. The juices of the manure will mingle with the salt, and be carried down to the roots by the rains and be of much benefit. But a new plantation must be made; therefore, in spring, procure a few one-year old plants, and plant them in rows 4 ft. apart and 2 ft. asunder in the rows.—E. H.]

Peaches.—P. S.—Either Lord Palmerston or Walburton Admirable will answer your purpose. Both are good late Peaches.

Names of Plants.—F. G.—The leaves sent belong to a species of *Rhododendron* from the Himalayas, but we cannot name it without flowers. *R. S. M.*—*Stapelia variegata*. *M. W.*—If you will send flowers we will endeavour to name it for you. *M. L. D.*—2, *Begonia Weltoniensis*; 3, *B. semperflorens*; 5, *B. fuchsoides*; 6, *Chrysanthemum maximum*; 1 and 4, Next week. *W. B. A.*—5, *Rudbeckia hirta*; 6, *Chrysanthemum frutescens*; 7, *Helleborus foetidus*; 8, *Centranthus ruber*; 9, *Sedum spectabile*. Others next week. *F. T.*—1, *Euonymus europaeus*; 2, *Hypericum Androsenum*. *M. O'R.*—The name of the Nilotic Lotus is *Nymphaea Lotus*. *P. J. N.*—The large flower is *Aster Amellus*, the other we cannot name from such a scrap. We cannot answer your other question.

Fruits, J. T.—Next week. *R. S.*—1, *Asplenium Trichomanes*; 2, *A. Ruta-muraria*; 3, *Adiantum pedatum*; 4, *Polypodium vulgare*; 5, *Doodia dives*. *Devon.*—1, *Aster Chapmanni*; 2, *A. Amellus*; 3, *A. bessarabicus*; 3, *A. ericoides*; 5, *A. levis*; 6, *Diplolappus linearifolius*. *Enquirer.*—*Centropogon Lucyanus*. *M. T.*—1, *Odontoglossum crispum*; 2, *O. maculatum*; 3, *Cypripedium barbatum*, *C. insigne*. *Amateur.*—*Erica cerinthoides*. *W. S.*—1, *Habrothamnus corymbosus*; 2, *H. fasciculatus*; 3, *Cestrum aurantiacum*. *O. P. Q.*—1, *Colchicum autumnale*; 2, *Asplenium C. byzantinum*; 3, *Crocus nudiflorus*; 4, *C. speciosus*. *F. G.*—1, *Lygodium scandens*; 2, *Pteris scaberula*; 3, *Pteris elegans*; 4, *Begonia nitida*. *Pife.*—1, *Rondeletia speciosa*; 2, *Combretum purpureum*; 3, *Jasminum Sambac*; 4, *Tacsonia mollis*; 5, *Fuchsia microphylla*.

No. 416.]

Vol. XVI.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

LEAFLETS.

It is pleasant at this season of the year to notice the things that preserve their verdure, or even assume a deeper tint, when yellow and brown leaves are falling everywhere. A Bamboo (*Bambusa Metake*) in Professor Owen's garden at Sheen pleased me very much the other day. One of its most graceful shoots measured over 11½ ft. in length without a break or shoot of any kind, the stem being a very delicate green, but nearly covered with brown bracts. In sheltered corners and on warm, well-prepared soils this Bamboo thrives very well about London, and is perfectly hardy.

In the same garden on the 2nd of November, with a cold northern breeze blowing, the eye was cheered with some spikes of the Cardinal-flower still fresh. There are few plants more brilliant, more beautiful, at this season of the year, or at any season, than the Cardinal-flower (*Lobelia cardinalis*). In America it is found in low and marshy grounds, but thrives well in any garden soil, though it does not often live through the winter on cold soils about London. In warm and light soils, however, it is hardy. There used to be a fine display in the College Gardens, Dublin, and no doubt Mr. Burbidge will again have plants that thrive so well there. I hope he may be able to get the fine species and varieties that were in cultivation some fifteen years ago. Messrs. E. G. Henderson used to have them.

I regret to notice a few not very good-natured remarks on the "Pinetum" of the late Mr. George Gordon, in the *Gardeners' Chronicle*:—"As an author," the writer remarks, "Mr. Gordon was not very successful, for his book was neither exact nor discriminative enough to take rank as a botanical authority, nor was it sufficiently popular in style to take a high position from that point of view, the technical account of each plant being too loose and wordy to be diagnostic, while the uses, adaptabilities, and geography of the several trees were not sufficiently elaborated to make it attractive to the general reader. It professed, indeed, to be a 'Synopsis' of the Conifera, which it was not, unless a classified table of the genera could be held sufficient to justify such a title." Mr. Gordon, it may be remarked, took the trouble to write what was admitted to be the best book on Conifers in English, and this criticism on the work of a man who, whatever his faults, gave us the book that has served the horticulturists of the United Kingdom well for a good many years, is both unmanly, unjust, and especially uncalled for and ungracious in an obituary notice.

This kind of reading will be sadder matter than it now is if what people have not done is to be compared with that which they have done. Most men, even among those who in early life enjoy "all the chances," as they are called, are content to do nothing, so far as adding to our knowledge is concerned. The great army of the Do-nothing's would probably gain some recruits if it becomes the fashion for the ghoul-erotic to perform his miserable wail over the graves of those who do the best they can. However, poor George Gordon had not many friends, and was not always his own, so it is not dangerous to say unkindly things of him.

I note the following reference to Mr. Gordon in Sir Jos. Hooker's latest report: "The very complete collection of cones and leaves of Pines belonging to Mr. George Gordon, late of the Royal Horticultural Society's Gardens, has been presented by the director, and deposited, the cones in the museum, and the foliage specimens in the herbarium. It contains the type specimens of almost every species described in 'Gordon's Pinetum,' a standard work amongst nurserymen and foresters, of which a second edition has lately appeared."

I should not be surprised if public opinion be some day aroused by the continual addition of small houses and private enclosures in the public parks of London, and a clean sweep be made of the lot. In fact, it must come to this, if the authorities do not put a stop to what is being done. Every structure of this kind means limiting the view, or presenting an ill-looking mass of brick, where one seeks the repose of trees or Grass. Then there is an enclosure, which limits the space that belongs to the public, and an addition of pathways, traffic, &c., to the house and its belongings, which in no way adds to

the charms of a public garden. Two structures have lately been erected in the Regent's Park which suggest these remarks.

I am pleased to see that the Rev. Canon Hole's popular book on Roses has been translated into German—an honour that does not often befall an English horticultural book.

In connection with the age of trees, it may interest many to know that in Earl Spencer's park, Althorpe, near Northampton, a stone with the date of their planting has been placed in the various plantations from Queen Elizabeth's time downwards. This custom was begun by Sir John Spencer. The 300 years' old Oaks, on which the herons now build, are, according to Mr. R. S. Baker, fine, tall-growing trees, with no appearance of age or decay about them. The plan, which is an excellent one, should be adopted in every place where planting is done. I know that it is being carried out at Thoresby, where the date of all the more recently formed plantations is attached to them in the form of an iron label let into the ground some 3 ft., and with sufficient base attached to it to render it immovable.

I see there is an interesting paper in the "Zoologist" on the two supposed kinds of British Martens. The conclusion of the author is that there is only one kind—the Pine Marten, now a native of Britain. In mentioning the localities, we think the author makes the animal appear to be too rare, and among the Irish ones we do not notice the county of Waterford, though it is so plentiful at Curraghmore that Mr. Speed tells us he had the greatest trouble to save the Peaches from its attacks. It used to go along the top of the wall, and, like a sensible epicure, help itself to many of the Peaches every night.

Are we not going wrong with our continual quest after "rich and sugary flavours," to quote words often used to praise fruit? A correspondent, who knows a good deal about Grapes, writes of the Paris Grapes:—"I liked the Chasselas, they were so refreshing, but we have some kinds equally good in England, only they are not in repute, because they do not produce big bunches. All the Frontignans, Duchess of Buccleugh, Black Prince, and others are crisp and good in flavour with a grateful aroma."

There is a good deal of humbug in our Grape-growing, and some pedantry I fear. The sensational bunch system has been the bane of culture to some extent. What a tale could be told of it! We only hear when success attends any one, but never of the utter collapse at the end of a few years in every case. Those at ——— had reached a low ebb last year, and this year they are absolutely barren and nearly dead. It is a case of stall-feeding and dying, like the fat bullocks in the Smithfield fog.

The public have every cause to be grateful to Mr. Bond for the way in which he has thrown the priceless treasures in the Library of the British Museum open to them. Mr. Bond began by abolishing the vexatious rule compelling every reader, whether he was of fifty years or fifty hours' standing, to show his ticket every time he entered. Readers known to the attendants enter freely, while those who are not recognised at once are asked to sign their names in a book for comparison with the signature on their ticket.

The next thing Mr. Bond did was to throw open two-thirds of the collection every day instead of closing the whole for three days a week, so that country sight-seers unacquainted with the open day are no longer sent away empty. The last great innovation is the introduction of the electric light into the reading room, so that readers can now remain there until 7 p.m. instead of being obliged to leave at 4, 5, or 6 p.m., according to the season. All this contrasts favourably with the spirit of opposition to the wants of the public shown at Kew, where, however, we do not despair of seeing a more sensible course taken in due time.

There is a pleasant story which comes to us from old times about Kew. One day King George the Third's gardener complained to him that the people plucked the flowers very much, and begged of him to close the gardens. "Do my people really pluck the flowers to that extent?" The troubled gardener assured him it was so. "Then plant more!" said the King. Of course, plucking flowers could not be tolerated in our days under any circumstances; but preventing people seeing them at any hour that the sun sees them is really too bad. Speaking of gathering flowers in public gardens, I was surprised to see people picking Cowslips in the charming grounds of the Little Trianon at Versailles some time ago, and wondered that in such a police-awed country as France it was permitted. The sentry at the gate, however, made the people part with their noses, and a vast

heap of Cowslips and wild flowers beside him at the gate showed the extent of the depredation.

*
 "Our country is full of poor ministers and poorer lawyers, and shockingly poor doctors, who ought to have been good shoemakers or farmers, who reached their present and unprofitable station by aiming too high." Thus speaks the *New Hampshire Mirror*. "Isn't that a mistake?" asks Dr. Hoskins in the *Vermont Watchman*. "Didn't they aim too low? But, if they aimed too high in trying to be professional men, would it not have been a fault in them to have aimed still higher? For it takes a great deal more brains and energy to be a successful cultivator than to succeed in professional life, according to our observation and experience."

*
 It would appear that our American cousins are continually tormented by a race of men called "Tree pedlars," of which we in this country happily know nothing. The mission of these individuals is to run about the country to sell trees, and some of them try to add to their business by describing all sorts of marvellous, but impossible, novelties to farmers and other persons ignorant of trees and horticulture. Complaints are continually being made in the American papers. I see by a letter in *Nick's Monthly* that certain tree pedlars in Kansas are selling a blue Rose, and claim it to be from San Francisco. As no such Rose is known here, or anywhere else, it must be put down as only another case of humbug. But a blue Rose is modestly to what they have been known to offer; they have been known to describe to us the future produce of the fruit trees they sell. Though the food and wealth-producing capacities of the country are almost inexhaustible, they are not for these gentlemen enough. Judging by articles in the rural papers, and particularly in the *American Agriculturist*, the number of persons who regularly pursue this most impudent kind of swindling seems far greater in America than here.

*
 One of my pleasures is to take up the *Californian Horticulturist* and see what is doing in that far-off sunny land of mountain, noble forest, and warm plain; and which, more, perhaps, than any other country, has been rapidly turned into a garden land. As everybody knows, the first people only settled in it in 1849. Mr. Shinn, the editor, writes very pleasantly on the native and garden plants of the country; and one often sees a sketch of some beautiful plant-life peculiar to the country, and yet interesting, because it often concerns plants that are hardy with us.

*
 Here are a few words on Lilies of native cultivation:—"The mountain children whom one meets on their way to school these July mornings, load themselves down with what they call Tiger Lilies, or in other words, *Lilium Humboldtii*, whose spires flash out with wonderful brilliancy around the bases of volcanic rocks, or near shattered ledges, or on the hard red clay of the hillsides. One of our authors, who studies with loving and analytic mind the colours and sounds and meanings of the Sierra woods, has called it "carnation-hued," with its orange and amber ground, veined with black. In favourable places we have found Lily stems as tall as a man. The bulbs are deep down, and not easily dug out. Some insect bores into and ruins many a choice bud. This Lily loves company, being always found in groups. Where you see one yellow flash you may be sure there are others near. After blossoming time is over, the stalks disappear very quickly. By following up the long ridges blossoms may be found in perfection for several months. The same is true of the lovely white Lily, *L. Washingtonianum*. Both species are in perfection in Nevada County."

*
 I see that Mr. Falconer, formerly of THE GARDEN, describes in the *Rural New Yorker* a horticultural club of a new kind:—"The ladies of Garden Street, which bounds the Cambridge garden on the west, have got up a club, which they call the Garden club. Their object is to assist one another in horticultural knowledge, by relating their experience regarding the cultivation of outdoor and window plants, experimenting with 'new' things, and clubbing together for the purchase of seeds and gardening periodicals. They meet once a week at some member's house when horticultural topics are discussed within, and the garden examined without." This is a very good idea, but can only be satisfactorily carried out where people are really fond of the art.

*
 Yet another letter to the *Times* about the trees in Kensington Gardens. "Living in Prince of Wales Terrace, Kensington, I am naturally interested in the preservation of the fine group of trees growing in the gardens just opposite to the end of the terrace. On Friday morning last, soon after nine o'clock, I observed that one of the finest of the trees had been cut down and was being carted away. On every morning since, except Sunday, another tree has

been cut down and carried away. The felling of the trees being done very early in the morning, and everything carried off and the ground duly levelled and set to rights before ten o'clock, is evidently done to escape observation.—HENRY THOS. COLE." One never sees the true remedy for the old and dying trees given in these letters, often as it has been given in THE GARDEN, that is, the planting annually in the best manner a certain portion of the ground in each park with the nobler hardy deciduous trees.

*
 Mr. George Syne, whose communications on various subjects have been published from time to time in THE GARDEN, has been appointed to the curatorship of the botanic gardens, Castleton, Jamaica, an excellent choice, Mr. Syne being well acquainted with plants in a living state, and also, as our readers know, familiar botanically with that most important family—the Coniferae.

JUSTICIA.

Destruction of Gardens in Spain.—The following extract from a private letter, dated Aguilas, Spain, Oct. 20, has been sent to us for publication: "You will have seen in the newspapers accounts of the awful storm that has visited us. Whole farms have been swept away, not only the houses and stacks, but the trees, crops, and even the earth down to the bare rocks underneath. About 20,000 Fig trees alone in this district have been uprooted and carried away, and the crops in the lowlands covered over with, in some cases, 3 ft. of stones, brought down by the swollen streams. At the farm of a friend of mine there is literally nothing left—Vines, Almonds, Fig and Pine trees, water-tanks, and garden, which had taken twenty years to get into order and perfection, all gone, and even the ground is all washed away. The news from Murcia and Lorca is fearful. The plain of the former, which was full of gardens of Orange and Lemon trees, groves of Olives, with other fruit trees of every description, is under water for a distance of twenty miles, and when this subsides the mud and debris will cover everything, and all the garden crops be spoilt. About 1000 houses round Murcia alone are calculated to have been either knocked down or carried clean away. Over 200 dead bodies have been found already, and the work is only just commenced. In Lorca, 32; Sierra Almagrera, 30; Puerta Lumbreras, 10; Alcantarilla, 8 have been found, but the number of missing is something beyond belief. At Lorca the water came down the river like a wall. The suburbs are more than half gone, and what was a few days ago a series of well-cultivated farms and market gardens, with pretty country houses and flower gardens, is now an immense mud plain—there is no other word for it."—*Times*.

New Paint.—The danger of inhaling the vapour of turpentine has been long known, and its pernicious influence on the health is beyond all doubt, as has been verified in several cases occurring in persons sleeping in newly painted rooms, some of which have even proved fatal. Several theories, more or less plausible, have been propounded to explain the prejudicial effects of the inhalation of these vapours: but, whatever be the correct explanation, there is no doubt of the danger of occupying a room recently painted in which turpentine has been employed, before complete desiccation has taken place. It was pointed out by the Council of Hygiene, that a sudden death which recently took place in Paris was attributable to this cause, it being shown that it could not be ascribed to the lead which entered into the composition of the paint of the room in which the deceased slept; the lead, being fixed and non-volatile, cannot in these cases be accused of being the offending element.—*British Medical Journal*.

Poisoning from Yewberries.—Children are very apt to pick and swallow the attractive berries of the Yew. The practice is a most dangerous one, and ought to be carefully kept in check, as is shown by the case of a little boy on whose body an inquest has been held at Oxford. The child, according to the *Daily Telegraph*, had been strolling through a cemetery with his friends, and, while playing about, he had plucked and eaten "a handful of Yewberries." No evil effect was noticeable until next morning, when he awoke in convulsions, and died before even a doctor could be fetched. The poison seems to have attacked the nerve centres, but in what specific manner it is not easy to say. Every poison is a possible remedial medicament, and therefore the Yewberry may have valuable uses. Like many other vegetable poisons, it does not seem to be made the subject of careful experiment, so that no antidote to it is known. Yet why should not toxicologists make a study of this and of several other common but baneful growths? Deaths are constantly occurring among children who pick and swallow these things, and science might do something to protect them against the fatal effects of their ignorance.

Leycesteria formosa.—This has flourished in my garden for many years without the slightest protection, and thousands of self-sown seedlings make their appearance annually.—J. H. N.

TOWN GARDENING.

It is a difficult matter to plant a town garden permanently on account of hot pavements and walls, and cold currents of wind. Many plants fail altogether, others pine, and others grow too large. Knowing indeed the frequent failures of such undertakings, we feel impelled to describe to the reader how we once planted, or helped to plant, a city garden, and how it looked when it was done. A friend had a piece of ground, on which he had erected a house as far back from the street as convenience would permit—some 20 ft. On this space he tried to grow Grass and plants, but did not succeed. Disheartened by failure, he came to us one spring, purchased some plants, employed two workmen, and in due time produced a piece of miniature lawn-planting, which appears in our illustration as it looked after ten years of careful fostering. The production of turf was of course first attempted. The lack of good turf is almost fatal to the beauty of any possible selection of plants. Here, where all is foreground in a certain sense, a large amount of the general tone and colour of the place must come from turf. Ornamentation becomes in such cases like the decoration of a room. The turf must make the carpet whereon the ornaments are to be arranged. In this case the unsatisfactory Grass was replaced by a turf of Ivy planted at intervals of 18 in., so that a thick mat of foliage could readily develop itself.

The Ivy turf recognised as the predominant feature, what plants do we notice first? Here by the gate is a Japanese Maple, one of the twenty-five varieties known in this country. It is nearly the most noteworthy plant in the lot, and demands attention still more because it presents one of the best instances of what the Japanese can furnish us for lawn-planting. The Maples of Japan are per-

they always require more skill to keep them healthy than deciduous trees or shrubs. The Japanese Cypresses or *Retinosporas*, as a group, have a remarkable fitness for city gardens, considering the fact that they, too, are evergreens. True, certain varieties grow to a considerable height, but most forms are slow and of moderate growth, if they are not actually dwarf. Their forms are indeed legion. They are drooping or erect, Fern-like or Lichen-like, and even pass into curious thread-like shapes. In colour they are golden, variegated, and green, but chiefly of a bright glossy green. At the time of the formation of this tree its size is about 1 ft., although it is by no means young. In future its spray-like forms will grow considerably, but pruning, to which it is specially amenable, will readily restrain it, without danger of malformation. This peculiar ability to bear with the utmost ease the strain of pruning distinguishes *R. plumosa aurea* above most other evergreens, and makes it well fitted for city planting. The general colour of its foliage is a broad suffusion of gold, which, when the plant has been pruned systematically, remains unusually bright in winter. No other evergreen, perhaps, equals it

A Town Garden.

haps most free from the peculiar characteristics that makes so many plants Japanese born and bred, wonderful, but not beautiful in our eyes. These Maples are miniature trees, with a free, full development that suggests neither deformity nor stunted conditions. Their dimensions would not in twenty years increase enough to unfit them for city gardens, though they never should receive a touch of the pruning-knife; and as to hardness, we can only say that in this respect they equal any Maple, with the added toughness of all dwarf trees. The leaves of these Maples are beautifully variegated during summer—white, green, and yellow mingling on the same surface, and these same leaves are divided and sub-divided until they become mere shreds of tissue. It is always curious to note that the most diminutive and complex types belong to the hardiest and dwarfest varieties. But we have not done with Japanese plants. Along the walk directly behind the Japanese Maple is a golden Japanese Cypress (*Retinospora plumosa aurea*). This arrangement has been intended to produce contrast between evergreen and deciduous plants, between a larger and more erect form and one smaller and more compact. Winter effects have also been considered in using evergreens, although it should be noted, at the same time, that evergreens are especially difficult to grow in cities. Occasionally they will die, and

in this quality, and it is a quality very valuable for city lawns, where bright and varied colour in winter is specially grateful. It is easily transplanted, and might be common, for it is easy to propagate. The general appearance of these *Retinosporas* resembles that of an *Arbor-Vitæ*, only they are more varied and spray-like in form, richer in colouring, and hardier and better in every way.

On the other side of the door-way we have a Japanese Snowball. The supreme excellence of this shrub lies in its rich character. Everything about it is excellent. The soft, brown, fuzzy stems, the dark green, heart-shaped leaves, piled in picturesque masses when the plant has been properly pruned, and above all, the large, pure white snow-ball flowers, make it very choice and attractive. Indeed, the contrast between the shining, crinkled green leaves and the well-rounded flower-clusters is always striking. These flowers, moreover, hang to the branches five or six weeks, and drop unbroken. Standing out prominently on the open turf is a weeping Hemlock of lighter and more rounded habit. Indeed, all these lines are models of curving grace. Like the Japan Snowball in the one quality of picturesqueness, it needs much the same care in pruning to develop its full charms and to restrain it and adapt it to a city garden. The beautiful sprays and tendrils should be encouraged in their irregu-

larities in order to obtain a characteristic and graceful form. Another prominent feature of this part of the picture is a beautiful *Spiræa prunifolia*, a deciduous plant intended to contrast with the evergreen Hemlock. The curious small leaves and the set of branches of this *Spiræa* are very characteristic and assort well in a group of varied shrubs. It is, moreover, the Bridal-wreath *Spiræa*, bearing lovely white flowers in June. Through the summer, its shining, oval leaves contrast strikingly with other foliage; and, late in autumn, few plants present more beautiful colours. Only two more plants await our admiration to complete the assemblage of more prominent shrubs and trees visible in the picture of this miniature lawn, and both of these are again Asiatic and one Chinese. The first, a tree-box, needs only to be mentioned to call up visions of stately gardens of the eighteenth century—clipped Yews and Box-trees wrought into the similitude of strange beasts and other quaint devices in the old formal manner. But now in our modern world, art is demanding the presence of nature everywhere. Except in retired corners, we cannot properly practice the old formal manner, yet we may still employ the Box-tree as satisfactory as ever. Very many city gardens show its value where the passage of years has left it healthy and flourishing. Probably nothing in the way of plants withstands injurious city influences better. Then, moreover, it is an evergreen—an evergreen shrub with distinct conspicuous leaves and vertical lines of growth which accord well with the architecture of city houses. Its bright living green is also compact and so patient of pruning as already noted, that its growth may be guided at will. Another plant, a Tamarisk (*Tamarix indica*), grows close by the corner of the house. Its waving elegance forms a strong contrast with associated shrubs and serves to lighten the general effect of the place. Very distinct and exquisite also is the foliage of the Tamarisk—fine as fronds of some delicate tropical Fern. The flowers come late in summer and early in autumn, fringing the foliage with drooping pink lace-work.

At a later date, two other striking plants have been added to the lawn with a view perhaps to replacing eventually some shrub grown old and unsightly. They are both Japanese, but the first, the Parasol Pine, is perhaps the most extraordinary lawn plant of the curious Japanese flora. It is greatly prized in Japan and grows there to a considerable size, with shining whorls of strange-looking glossy foliage disposed in thick masses. Perfectly hardy, it is likewise, on account of its dwarf nature, well adapted to small lawns during at least twenty years of its life. During the first three or four years, it hardly grows as many inches, and is always rich and unique in its appearance. As yet it is an extremely rare plant in America, where there scarcely exists a specimen over 4 ft. high. The second, the Japanese Cypress, is a very rare variety, decidedly the rarest plant on this particular lawn; but it is also very beautiful with its thread-like masses of golden drooping foliage. It is dwarf and well fitted for small places, and has an advantage over the common golden Japanese Cypress (*R. plumosa aurea*), inasmuch as it needs little pruning to retain a compact shape. Of all plants suited to the miniature lawn, few surpass in native charm the hardy herbaceous plants, many of them familiar wild flowers. On our miniature lawn, the less and less fashionable crudity called "ribbon planting" would be almost inappropriate, not to speak of the trouble of replanting such plants every year. All the richness of colour in flower and leaf of bedding plants may be obtained in a more delicate and fitting way for small gardens by the employment of hardy herbaceous plants and bulbs that flourish for years in the open ground.

Few other features of our city lawn remain to be mentioned. Star-shaped Clematises creep over the borders of the Ivy on the ground, as well as over the fence. Japan creepers cling to the stone-work of the lower part of the house, and from sundry nooks peep out white Snowdrops, yellow Crocuses, and the tiny bells of the Lily of the Valley. To vary further the colour of the green Ivy tuft, low-growing, richly coloured herbaceous plants, like the creeping yellow-leaved Moneywort, wander about at will. Purple Asters, blue Aquilegias, and lovely Day Lilies appear here and there on the out-skirts. Everything combines to make a very complete miniature lawn. But such lawns will not care for themselves. The shrubs need thorough culture, and especially pruning, to adapt them to their confined location. Summer pruning is very important, particularly for the Ivy, whose wandering tendrils need occasional training, as well as pinching. This care, however, is not irksome, for there is little to be done at a time; and in any case, we doubt whether other adornments of home will afford equal pleasure with less expense.

Let us now give our attention briefly to another typical, but entirely different, instance of lawn-planting, viz.: a country home of the commonly occurring dimensions of 100 ft. wide by 200 ft. long. Citizens going to their business daily, and possessed of moderate means, frequently occupy a place of this size in some neighbouring village or suburb of the city. Consequently, a few hints afforded by the description of an existing lawn will scarcely come amiss to

many, who, if they realize how much adornment of this kind is possible for them, must be sorely puzzled to secure the fulfilment of their desires. The place to which we refer is that of a neighbour, who a few years since purchased it, in a so-called improved state, and gradually has made it, from the crudeness and almost chaos of its former condition, a truly delightful spot. Originally, the lawn was covered promiscuously with Maples, Arbor-Vitas, old fruit trees, neglected-looking Rose-bushes, and rows of rudely-clipped shrubs. The new owner of the place changed all this by cutting down everything except a few trees along the fences, and two notable specimens, of which more hereafter. He then subsoil-ploughed the lawn, spading only such parts as the plough could not readily reach, and sowed it with Grass seeds.

Good turf obtained, the walks were carefully laid out in long, graceful curves, with shallow Grass edges, neatly trimmed. Every winter fertilisers were applied to enrich the Grass, and a perfect surface was always maintained throughout the season by the use of a lawn-mower. The house, being on the north side of the garden, afforded abundant protection for choice plants, and secured the employment of large and effective masses of evergreens, as part of the same shelter. Among the trees that had been preserved from the general destruction that befel the old plantation, were two specially

Weeping Pine (*Pinus ayacahuite*).

attractive specimens. It was really wonderful how they came to occupy the positions they did, and indeed, how they came to be on this lawn at all, for the other trees used were by no means choice or rare. These two specimens, on the other hand, were both choice and somewhat rare. One of them, the Cut-leaved Weeping Birch, stood by the summer-house and hung graceful sprays above its rustic angle. Indeed, at this point in the picture, the bolder colour effects of the lawn-planting seemed to culminate. Rising 30 ft. above the summer-house, the white bark of the Birch split into strange devices, and the delicate grayish-green foliage made a fine effect against the masses of large Norway Spruces near by. The other noteworthy tree retained is a Nordmann's Fir, by some termed the king of evergreens. It stands by itself, equally removed from the clustered shrubbery of the outer boundary, and from the choice plants along the only footpath. After the Cut-leaved Birch, it is decidedly the most imposing and important tree upon the lawn. Growing as it does in a massive, stratified manner, with a blue silvery lining under the leaf, the compactness and symmetry add greatly to its beauty. And what a grand specimen it is—30 ft. high and without a flaw!

Two varieties of evergreens are grouped about or near the Nordmann's Fir. They are small, 6 ft. to 9 ft. high, and were planted by the new owner some eight years before. Their arrangement has been made with the view of affording a measure in height for the larger trees as well as a complete and harmonious contrast of colour.

The most noteworthy of these is *Pinus ayacahuite*, a rare Mexican Pine of decided beauty, of which we give an engraving. Although this Pine comes from Mexico, it is generally hardy in the Northern States; it is the nearest approach to a Weeping Pine that we have, if we except *Pinus excelsa*. The branches, indeed, do not droop, but the long pendent clusters of needles give a weeping appearance to the general effect of the tree. In the young plant the shape shown is decidedly pyramidal; but as it grows older, it assumes more of the usual spreading appearance of *Pinus excelsa*. The latter has occasionally suffered from a peculiar disease,—but for beauty of colour and form it is nearly equal to the *Pinus ayacahuite*. We notice even now in youth that *P. ayacahuite* has a more open appearance or branching than the Nordmann's Fir, against the shining dark masses of which its rich blue colour stands out in beautiful relief. There is a slight resemblance between the outline of this specimen and that of the Nordmann's Fir, but not too much when accompanied by contrasting bluish-green colour. The growth of this tree is moderate and easily restrained by pruning, to which it takes very kindly. To complete a harmonious and richly effective arrangement, three pyramidal *Arbor-Vitæ*, at that time 3 ft. or 4 ft. high, were planted within 2 ft. of each other. Standing singly near the Fir and Pine, one plant of this *Arbor-Vitæ* would have been almost too slender and insignificant; but three specimens, growing together at the base and developing independent spire-like heads, give variety of form and sufficient size to bear a proper relation to the graces of the other trees. Their colour, too, is light, lighter than that of either of the other trees, thus affording a complete contrast of hue as well as form. This *Arbor-Vitæ* is thrifty in habit and perhaps harder than any other of its race, and above all keeps its formal shape with little pruning.

It is a fortunate thing for the lawn that it occurred to some one

growth, is unsurpassed for weeping grace. Imagine one of these naturally weeping specimens fixed permanently by grafting at the best development of its pendulous habit, and you have the true Weeping Hemlock. It is indeed rare and difficult to propagate, yet it would, nevertheless, be brought into common use could people generally see its great beauty.

Near the Weeping Hemlock, with perhaps a deciduous shrub or so between, are four very distinct dwarf evergreens, distinct and curious, especially from the manner in which they are grouped. They consist of the Weeping Norway Spruce surrounded closely by three dwarf White Pines. Norway Spruces and White Pines are always associated in our minds with large, massive forms, but here are White Pines that in twenty years need scarcely reach 4 ft. The Weeping Norway Spruce, too, is dwarf, but in a very different way. The forms, moreover, are perfectly natural, in no way the result of pruning. And what curious plants they are—the one rounded and

A Suburban Garden.

to plant the Nordmann's Fir just where it stands, for it is the making of the place artistically considered. Colour as well as form are here grouped harmoniously and yet boldly. The variety in height, the different shades of kindred colour, the columnar, spreading or open, and the massive conical forms, all combine into an instance of what we conceive to be good lawn-planting composition. A sense of coziness is suggested by the semi-detached lawn or croquet-ground of this part of the place—features that are defined, as it were, by this very group. Further variety of detail is given to the scene by climbing Honeysuckles and Wistarias clustering about the rich, solid proportions of the rustic summer-house. Across the lawn, past the border of the croquet-ground, is a beautiful Japan Judas Tree; it is a lovely shrub, with early pink flowers and rich green leaves, and does not grow high enough to interfere with the sunset view. Across the path from this plant is a group of the rare and exquisite Japanese Maples. Nearer the house, and still on the path, is a graceful Weeping Hemlock, already noticed as one of the choicest of evergreens. The common Hemlock, in certain conditions of its

compact, with long, well-defined needles and softly-blended colours of blue and green, and the other dark, grotesque, and erect. A little farther along the border of the walk, and near the turn leading to the front of the house, stands a Rhododendron. This beautiful plant is specially effective at this point, as it not only varies the curve of the walk, but presents a delightful object in view of the bay window, about which are Ghent Azaleas and other flowering shrubs.

It is not, indeed, an expensive lawn, having scarcely cost \$500 for all the plants; but there is something of everything hardy to be found on it. Blue and white Wistarias form a cordon of bloom along the eaves of piazza and balcony, and Honeysuckles, Virginia Creepers, &c., fill a part of the space between the columns. The Japan Creeper and the great purple or white flowering Clematises creep about here and there. Young vigorous Roses bloom in nooks of shrubbery. Violets peep out early in unexpected places, and familiar wild flowers lurk in favoured spots. There is no startling display of beds of flowers, any more than there is in woodland glades; but the plants seem at home. In front, along the road, is a wall of

solid masonry, neatly capped with stone by the new owner, and covered with Japan Creepers. Immediately within are Purple Beeches, rich and dark. A Weeping Beech stands in the corner where its expanding foliage has plenty of room, and at intervals are fine flowering shrubs of large size, like the Chinese Magnolias. Along the path to the front door are planted choice dwarf deciduous shrubs. The outlines of shrubbery and trees have been made up in the ordinary way, with Norway Spruces, White and Scotch Pines, Elms and Maples, with such common large-growing shrubs as Lilacs, Philadelphuses, Dogwoods, Spiræas, and Weigelas. The grouping of these ordinary shrubs and trees is naturally arranged after that of attractive bits of outlying woodland. The perfect keeping of the paths of this place is also noteworthy; but better still is the regard shown for the health and well-being of the plants. Contrary to the usual habit of people who have no gardener, the plants have not been treated according to the mere advice of others, but have been made to thrive in a peculiar way by a painstaking study of their individual wants. —*Scribner's Monthly.*

HORTICULTURAL EDUCATION IN ENGLAND.

ANY one who thinks of the state of horticultural education in England must be struck with the total inadequacy of any provision for it. However much one may doubt the benefit of such teaching as a young man can get in one place such as we at present possess, nobody can doubt that it would be possible to teach in a properly organised horticultural school a great many things that would be of the highest importance for a gardener to know. It would, for instance, be very easy to arrange a country garden, so that young men, sufficiently intelligent to do so, could learn all about the hardy ornamental shrubs and plants. The fact that this is not taught is a great loss. It is the cause of the utter want of interest that exists in the majority of country seats and gardens, and it is entirely owing to this that people interested in them are unacquainted with the great number of beautiful things which they might have around them. Intelligent men, even in good places, do not often know the names of some of the most important hardy trees around them; and this is not so much their fault as that of the want of some proper provision for teaching these things. If it were a fixed law that the country should spend no money in founding institutions of this kind, one could at least understand it; but the fact is that enormous sums are now annually given for City and State horticulture in the public parks and gardens of London, and it is to be regretted that some of the liberal means thus provided are not devoted to systematic teaching. We have, however, hitherto been accustomed to consider that the sister art of horticulture, *i.e.*, agriculture, had been better off in this respect; but this is not so, judging by the following remarks which appeared in the "Country Gentleman," and which are well worth reading by all who care about the progress of the rural arts in our own country:—

Among the agricultural educational agencies in England, one naturally thinks first of the Agricultural College at Cirencester. This institution is the only one of the kind in England, and has been in operation for a long series of years—sending out its first graduate in 1847. The total number of graduates has been 207, the average for the last seven years being seven. The number of students has never been large, and is now smaller than it was some years since. In a number of respects the institution is quite different from anything in America, and I paid it a hasty visit with interest. I can hardly say I was disappointed, but I certainly came away with not very much hope of wide usefulness for the college. The facilities for instruction are fair, no more. The college building is large, rather showy, but not very suitable for the purpose. The library, museums, &c., are not large nor remarkable—not nearly equal to those of several of our State agricultural colleges. There is a veterinary hospital and a small workshop. The faculty includes the principal—in whose charge the institution is placed—and professors of agriculture, chemistry, mathematics, natural history, veterinary surgery, drawing, and two lectureships. The course of study extends over two years, and seems well arranged to "train men for agricultural employment, whether as owners or occupiers of land, land agents, or stewards." No attempt is made to give a general education. The course is made up of instruction in agriculture and veterinary science, with chemistry, botany, geology, physics, some mathematics, and drawing. The first obvious obstacle to the wide usefulness of the college is that it has seemed necessary to make the fees paid by the students so high that the class which one would naturally expect to be most benefited by the college are not able to attend it. Thus the annual charge for "in students" is £126; for "out students" £51. Where the student wishes a private room in the college building, he pays £27 additional. Of course only men of comparative wealth can pay such fees, and, as a matter of fact, the sons of common tenant farmers do not attend. The students are generally sons of wealthy

land-owners, who wish to gain some knowledge as a help to managing their own estates, or young men who are preparing to be estate agents. It is the exception when a student expects to become a practical farmer in our American sense of the words. It will readily be imagined that such students as do attend will not, as a rule, interest themselves very heartily in the practical part of the agricultural instruction. They may or may not take interest in the scientific studies.

What is called the college farm contains about 500 acres. It is owned by Lord Bathurst, and occupied by Mr. Russell Swanwick, the well-known Cotswold and Berkshire breeder, and a graduate of the college. Mr. Swanwick largely delegates the management of the details of the farm to his bailiff, or steward, who is an intelligent, common-sense Scotchman. The college has no control of the farm, but its students and professors are permitted to go over it at any time, and the students are expected to keep an account of the daily operations on it. Daily class visits to it are provided for in the programme. The college has been quite unfortunate in having frequent changes in its faculty. Within a year three or four changes have been made. These have caused a great deal of adverse criticism in the English agricultural papers. It is clearly evident that the principal has not been fortunate in his management in a number of ways. Except the principal, those of the faculty whom I saw were young men. Prof. Cathcart, in charge of the Agricultural Department, is quite young, but is spoken of as a good student in his specialties, and impresses one with his intelligence and interest in his work. One feature which impressed me favourably was that of having an examination in practical agriculture conducted by a representative farmer, which intending graduates must undergo. This year this examination was conducted by Mr. John Clay, one of the most successful farmers of the south of Scotland. Among the graduates of the college there have been some strong men. Careful attention to the course of instruction as laid down could not fail to be of much help to any one proposing to interest himself in agriculture. It is much to be regretted that the institution is not able to arrange so that the poorer classes of tenant farmers could send their sons to it, and that it does not possess the hearty good will and confidence of the farmers of the country.

The British government has done comparatively little for agricultural education. The college is in no sense under government patronage. Quite recently the government has arranged to have courses of lectures given on the elements of science relating to agriculture in different parts of England; that is, it aids such lectures by giving payment to the lecturers or teachers for every pupil who passes a satisfactory examination on the course given. In further aid of such instruction a course of lectures was given last July, in London, under the auspices of the Science Department of the South Kensington Museum, by Professor Henry Tanner, to a class of seventy science teachers. Of these fifty were selected by the government, and their expenses paid; the others attended at their own expense. I had the pleasure of hearing two of these lectures, and was much pleased with them. Professor Tanner is well adapted for such work. He is more than usually clear and forcible in statement, and very fortunate in the use of illustrations. Two difficulties occurred to me as I listened. The teachers present were intelligent, fairly educated men; but I suspect very few of them had any particular acquaintance with agriculture save in the most general way, and I am not at all sure that listening to a course of forty good lectures would very well fit them to give the instruction which would be useful. The second difficulty is much more serious. I do not see much prospect of their securing classes to which they may lecture. It can hardly be expected that farmers will attend such lectures, and I fear few neighbourhoods contain many men who will feel such an interest in the matter that they will be willing to send their sons and pay the necessary fees—for the government payment is only designed to supplement the fees paid.

"*Dictionnaire de Pomologie.*"—This excellent book, by Mons. André Leroy, of Angers, has just been completed, so that it is now possible to see in its entirety how noble and how useful is the work he has done concerning all our hardy fruits. In this country we have never had anything like it for completeness and trustworthiness. The history, names, and synonyms of the fruits are thoroughly treated of; but, still more important, the questions of culture and propagation receive the share of attention that they deserve. These points have been too frequently overlooked in books which dwell enough on technicalities, and leave out the greater questions of culture, adaptability of the tree to certain stocks, soils, or climates. In Mons. Leroy's book the stock that the particular kind does well upon is indicated, and there is a sectional drawing of most of the varieties. The whole plan and execution of the work forms an excellent memorial of its now deceased author, also so

favourably known by his famous nurseries at Angers. The book, which forms a valuable addition to the country house library, may be obtained at our office, and the six volumes cost 30s.

ST. JOHN'S VICARAGE GARDEN, RYDE.

A NEIGHBOUR of mine, not particularly (as will be seen) distinguished for his love of flowers, some two years ago exchanged duties with the vicar of St. John's, Ryde. Knowing what an ardent lover of flowers the latter was, I said, "You must have been delighted with the garden." His reply was, *Horribile dictu!* "the most untidy garden I ever saw." It was in this "untidy garden" that I spent a couple of most pleasant hours the other day with my friend Mr. Ewbank, whose name is so well known to all readers of THE GARDEN as an enthusiastic and successful grower of herbaceous plants; and I could quite understand what my neighbour meant. Had the garden been arranged in beautiful geometric order, with beds of flaming colour, or with patterns of butterflies, grasshoppers, &c., in carpet bedding, he would have been in ecstasies over it; but arranged as a herbaceous garden, and seeing it in August, when such gardens are not at their best, he could find no other term for it but this. Need I say I did not find it untidy, and that I gained much valuable information in chatting over our favourites.

That Mr. Ewbank has great advantages, both in situation and soil, he is the first to acknowledge. In the first place, the Isle of Wight is well known for its mild and genial climate as compared with the mainland close by; then he has, perhaps, the most favoured garden in Ryde. Facing him is a large belt of fine trees, which effectually shade him from the east and north winds, which, even in the Isle of Wight, are so injurious to vegetation. His garden lies fully exposed to the south, and, consequently, the only difficulty he has to contend with is want of shade; but this he has managed to overcome in the case of plants particularly requiring it. The soil is a good free loam, which suits so many herbaceous and Alpine plants; and then his garden is elevated on the top of the hill outside Ryde, on the road to Havenland and Brading, so that he escapes the damp and fogs to which the lowland gardens are exposed. All these are great advantages, but they are advantages which a less experienced gardener would not make so much of as Mr. Ewbank has done. At the risk of making the mouths of some of our hardy plant lovers who read THE GARDEN water, let me mention a few of the plants which do well in the open air. These are *Habrothamnus fasciculatus*, most vigorous; *Mandevilla suaveolens*, *Eucalyptus*, *Cantua dependens*, *Agapanthus umbellatus*, and *Daphne indica rubra*. This will sufficiently show how exceptionally mild the situation must be, when, after such a severe year as that we have passed through, these plants should be flourishing and showing no symptoms of suffering.

The front of the house is beautifully covered with creepers, variegated Ivies, &c., and the east end of the church abutts on the garden, so that it is impossible to imagine anything more delightful in the way of a vicarage than this is. Let not your readers imagine that all this implies the *dolce far niente* of an idle life; the church is a very important one, and Mr. Ewbank shows the same zeal and energy in the management of his parish that he does in the cultivation of his garden; indeed, but for the relaxation afforded by the one, it is doubtful whether he could so effectively endure the labour of the other. In the front of the house, facing the north, he has made a bed for his Lilies, and another for *Cypripediums*, *Trilliums*, and such moisture and shade-loving plants; and fancying that the roots of the trees and shrubs might intrude themselves into the Lily bed, he has made a wall under ground about 4 ft. deep, so as to prevent their doing so. As he believes that damp getting into the crowns of Lilies is the great cause of their not succeeding in the open air, he has just had made some covers—simply two pieces of wood nailed together like a roof, which will just cover the crown of the bulb in winter, and so throw off the water. There are one or two other protectors which he has contrived, and which have been already mentioned in THE GARDEN, but which I must notice again as being very effective for the purposes he has designed them for. One is a circle of perforated zinc, which he uses for the purpose of keeping off those enemies of the rockery or border—slugs, which so often prove destructive to the more tender and delicate-growing Alpines. The other is simply the placing of a sheet of glass over some of those plants which suffer from damp getting in among the foliage, as many of the Alpine plants coming from very high elevations are covered with snow during the winter months, which effectually wards off the damp, and then when the snow melts in spring they are pushing on their growth and able to take care of themselves. We cannot cover them with snow, but a protection of this sort may be a good substitute for it. It is astonishing how many different species may be grown in a garden of this description, especially

where care is given to make a selection rather than to form a collection of species. Thus there are a large number of the *Michaelmas* Daisies, and for those who have a large garden it may be interesting enough to have them, but an ordinary lover of flowers will be satisfied with some six or seven good varieties. Then again the *Alliums* are a numerous family, but except for a botanist some five or six of the best are all one would care to grow; and in mentioning some of the plants which I saw in Mr. Ewbank's garden, either on his rockery or in his borders, I am only taking a few of those which especially came under my notice.

There are a few plants about which, when I go into an herbaceous garden, I am always sure to enquire, as they seem to me to test the skill of the owner or the excellence of his situation and soil—*Androsace carnea*, *Gentiana verna*, and *Eritrichium nanum*. Now with regard to the two first of these Mr. Ewbank has succeeded admirably. He has fine tufts of *Gentiana verna* growing on the flat, but somewhat elevated, and there was even a bloom of it expanded in this most curious season. He has also fine healthy cushions of *Androsace carnea*, and this is one of the plants which he protects with glass in the winter. With regard to the third, the *crux* in herbaceous plants, he said, "Had you come a few days ago I should have pointed this out to you as one of my successes; but, alas! now it is going." Whether the gardener omitted to put the glass over it in time, or whether it was the inherent perversity of the plant I know not; but, unhappily, Mr. Ewbank must be added to the number of those adventurous spirits who have tried to woo and win this fair Alpine beauty, but who, though they have wooed her ardently, have failed to fix her affections. By-the-bye, why is it that so many of these Alpine beauties are blue? Is it that being so much nearer the sky, they draw their tints from it? *Gypsophila paniculata*, a most delightful subject for cutting for nosegays, I have never been able to manage. Here it was flourishing, and Mr. Ewbank told me that the secret was to grow it in peat. Another very pretty little plant, and covered with its yellow flowers, was *Oxalis lobata*. The two *Honeysuckles*, *Lonicera Standishi* and *L. fragrantissima*, are valuable for producing flowers in winter, as does also *Vinca acutiloba*, while the foliage of *Berberis Fortunei*, which turns to a brilliant scarlet in the autumn, is also not only pretty in the garden, but adds to the effect of cut flowers. There were some grand looking plants of *Eryngium*, especially *paniculatum*, succeeding well here, but I am doubtful about it in our cold climate. *Daphne Blagayana* is a very distinct species, with white flowers, and very fragrant, requiring a shady place. *Tritoma grandis*, the latest flowering of all this showy species, is very noticeable on that account, but in this season all of the *Tritomas* have been late. There is a great difference evidently between the time of flowering of plants here and in Kent. *Schizostylis coccinea* was in full bloom, while with me it was only just commencing to show its flower-stems, and what a brilliant autumn plant it is. *Aplopappus spinulosus* is a bright yellow flower, and blooms late on into the autumn. *Senecio pulcher* was nearly out of flower, but had been very fine; it is a grand autumn flower.

There are a large number of *Iris* of different genera grown here, and all seem to be doing well. Thus *Iris susiana*, which I have been unable to flower, here does very well; and, contrary to the general habit of the family, requires to be grown in a hot sandy place. *Iris stylosa* is amongst the best for its valuable property of displaying its brilliant blue flowers in the middle of winter. The *Kämpferi* section were all in full vigour, and had flowered well; and *Iris alata* and hexagona were spoken of as good species. Of the *Michaelmas* Daisies *A. Chapmanii*, a bright blue, was very fine, and also *A. Novæ-Angliæ*, *A. bessarabicus*, and *A. carnaticus*.

Of course the autumn flowering *Crocuses* were very pretty, *Crocus speciosus* being amongst the most lovely of them, and *C. Imperati* was exceedingly striking from its large and showy flowers; *Crocus pulchella* was also pretty. *Dianella œrulea*, with broad grass-like foliage and blue flowers, is a very desirable plant, as the flower is followed by bright, showy-looking berries. *Desmodium penduliflorum* is also another bright looking and easily grown plant, while *Cardamine pratensis* fl.-pl. is a pretty variation of our common English Cuckoo flower. *Geranium sanguineum*, also another native plant, is exceedingly pretty and continually in bloom. *Rosa rugosa* and *rugosa alba* were covered with their large remarkable-looking hips, and are doubtless very charming additions to our lists of ornamental plants, whether in flower or fruit alike pretty. Amongst the numerous family of *Saxifrages* so diverse in their character and appearance, *S. peltata* was doing well in a damp corner; *Saxifraga cœsia*, on the other hand, with its small, close rosettes, requires to be covered with a sheet of glass during the winter, as the damp is liable to rot away the foliage and so destroy the roots. Of the *Meconopsis*, Mr. Ewbank spoke highly of *M. Wallichii* (blue) and *M. nepalensis* (yellow), though he considered both as only annuals, *M. aculeatus* being also another desirable variety and perennial. *Veronicas* do uncommonly well here, and Mr. Ewbank said that

cutting them down in spring secures a good and late bloom in the autumn.

I also noticed in the greenhouse *Vitis hederæfolia*, which has bright blue berries and is very ornamental; while many other choice things one does not often see were here doing well.

It is, of course, impossible to enumerate a tithe of the plants grown in a garden like this, especially as so few were, comparatively speaking, in flower; but I have shown, I hope, what a rich garden it is, and how zealously Mr. Ewbank has contrived to collect in it some of the very choicest herbaceous plants, and has thus created for himself and his friends a never-ending source of enjoyment. DELTA.

THE FLOWER GARDEN.

VARIETIES OF PAMPAS GRASS.

To my mind the Pampas Grass loses half its beauty when not in close association with other forms of vegetation. It never appears so much at home, or displays itself to so great advantage as when springing up from amongst low-growing evergreen shrubs. The light, airy, graceful disposition of the foliage is never so well shown off as when backed up by, and partially surrounded by, compact-habited, dense-growing trees; and if the foliage of these latter should happen to be of a dense lustrous green, it serves to bring into greater prominence the silvery nodding plumes which, when well developed, form such conspicuous and charming ornaments to the pleasure-grounds during the autumn months. The Pampas Grass, when well-flowered, is such a noble addition to our gardens that it is truly a matter of regret that so many worthless varieties should be distributed. A complaint often made is, "My Pampas Grass grows well, but it never opens," and eventually the owner arrives at the conclusion that either his soil or situation is unfavourable to its growth, and discards it, when after all the failure is wholly due to a late flowering or worthless variety.

This season has been extremely unfavourable to the development of the Pampas Grass, and yet I have this autumn seen spikes of bloom, the beauty of which could hardly be surpassed. The plants bearing them were grown singly among the ordinary trade stock of a nursery, and were really models of what a Pampas Grass should be at this time of the year. It was not the size of the specimens which attracted my attention, but rather the neat habit, quite devoid of that rank coarseness which distinguishes so many varieties, and which renders them quite unfit for small gardens, and the graceful disposition and wonderful purity of the flower-heads. The quality of the latter was a matter of surprise to me, considering the adverse character of the season, as they almost equalled in appearance some plumes in my possession from the favourable climate of California. The remarkable beauty of these Pampas Grasses—so much alike, and yet unlike anything which I had hitherto seen—caused inquiries to be made upon the subject, and it was then found that they all sprang from one or two plants. The owner having had the good fortune to obtain an extra fine variety, resolved to retain it, and therefore propagated it by means of offsets. This, therefore, was the reason why the specimens were all good and of equal quality, a result hardly attainable where seedlings alone are relied upon.

It is to be regretted that we could not, in a general way, thus obtain our Pampas Grass, propagating from tried selected plants rather than planting seedlings, which appear to vary in a remarkable manner, and which often prove so unsatisfactory to the grower. A large stock is, I presume, most readily obtained by means of seed; but I imagine that but little difficulty would be experienced in working up a large quantity from a few plants were the necessary means taken to ensure a rapid growth. A free rich soil is what the Pampas delights in, and it increases rapidly in bulk when thus accommodated. Once a stock is obtained, there would be but little difficulty in maintaining it, and both vendor and purchaser would have the satisfaction of knowing that every plant would be certain to bloom well and at an early date. Even supposing the plants to cost more when thus propagated, would it not be better to incur a little more outlay, and thus avoid the vexation which must arise when the grower finds that he has filled valuable space and expended care and attention upon a plant which can never afford him any pleasure. A Pampas Grass that does not bloom early enough to develop its plumes is not of much use from an ornamental point of view, and a few such plants in a district will often exercise a deterrent effect upon planters. I would advise those who may wish to make extensive use of this noble Grass to procure a plant which has flowered satisfactorily and propagate from it; better wait a season than incur disappointment by planting seedlings. I should add that in the case of the plants above mentioned, they are by no means

favourably circumstanced, as they are growing in soil of a cold nature, and the situation is rather bleak; to the merit of the variety alone must, therefore, be ascribed the present very fine effect which the plants produce.

J. CORNHILL.

Byfleet.

THE GUNNERAS.

THE resemblance in general appearance of the now well-known *G. scabra* to the rarer kind *G. manicata* has induced not a few to consider them as one and the same species. They are, however, abundantly distinct, as may be seen by the accompanying woodcuts, which represent the form of the leaves and the relative size and shape of the singular flower-spikes. Mr. Green, gardener to Sir G. Macleay, knowing that the two species were generally considered identical, exhibited at South Kensington, on September 16, the fruiting spikes and leaves of each kind from the garden at Pendell Court, in order to show the difference between them. From these specimens our engravings were prepared. It will be observed that the leaves of *G. manicata* are much more kidney-shaped than those of *G. scabra*, and they, moreover, attain a much larger size, often measuring as much as from 4 ft. to 6 ft. across. The spikes of fruits also are very different from those of *G. scabra*, being much longer, and the secondary spikes are long and flexuose, whereas in *G. scabra* they are short and stiff. Both species are highly deserving of a place in any garden, for no plants in cultivation are so stately as well-grown examples of these two Gunneras. The largest plant of *G. manicata* which I have met with is in Sir G. Macleay's garden, where it is grown near the edge of a

Gunnera scabra (showing the habit of the plant).

lake; in this position the roots penetrate deeply into the moist soil, in which they delight; indeed, if both of the species are to attain a large size, it is indispensable that they should have an abundant supply of moisture at the roots, especially during the growing season. Perhaps the finest plant in the country of the better-known *G. scabra* is the noble specimen at the head of the herbaceous ground at Kew; it measures from 10 ft. to 15 ft. through, and 8 ft. high, and often develops leaves from 3 ft. to 4 ft. across. This specimen has attained these dimensions in a comparatively short time, as it was only planted a few years ago. The success attending it is probably due to the precautions which were taken in planting it at first. A large hole, about 6 ft. by 4 ft., deep was dug out; a good layer of drainage material was put at the bottom and filled with a rich compost of loam and manure. In summer the plant is allowed a plentiful supply of water, and, in order that a large quantity may be given at each application, a circular ridge of turves is placed round the plant, so that the water is compelled to sink down about the roots. It has, in addition to this, an annual mulching of well-rotted manure; this is given in early spring. Both *G. scabra* and *G. manicata* are apparently about equally hardy; indeed, they may be termed quite hardy if a slight protection is afforded during the severest cold. For instance, during last winter the Kew plant was perfectly uninjured, though it only had a layer of dry leaves placed amongst the stems, with its own leaves bent down upon them, which in spring were removed, and the tender growth afforded a slight protection by means of a piece of canvas shading or an ordinary mat. In mild winters this precaution is scarcely necessary, especially in the south and other more favoured localities.

All the species in cultivation are natives of South America. *G. scabra* inhabits sandstone cliffs and similar places in various parts of Peru and Chili, where it was seen by Mr. Darwin in his travels in those regions. He speaks of it as somewhat resembling Rhubarb on a gigantic scale. It is there called Panke, and the sub-acid

THE CULTIVATED SPECIES OF GUNNERA.

stalks are eaten by the inhabitants; they also tan leather with the roots, and prepare a black dye from them. Mr. Darwin met with specimens bearing enormous leaves which measured 24 ft. in circumference, and therefore about 8 ft. in diameter. By way of illustrating the great diversity of size and habit which often exists amongst plants belonging to the same genus, a life-sized leaf of the diminutive *G. magellanica* is here given, it being the only other kind of *Gunnera* in cultivation in this country at the present time. It does not attain more than 2 in. in height, and has a creeping habit. I have not met with it in fruit, and probably it rarely does fruit. This species thrives in a peaty moist soil in a shady position. Another kind now lost to cultivation, somewhat similar to this in habit is *G. perpensa*, a native of the Cape of Good Hope, and which was a few years ago to be found in some collections. *G. falklandica* is also another dwarf-growing species.

W. G.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Variegated Grasses.—"C. M." (p. 392) by no means exhausts the list of hardy Grasses with variegated foliage. Herewith I furnish a list of some which he has not mentioned, and though possibly a few of them are not so showy as *Dactylis glomerata elegantissima*, most of them are very useful border plants, and for cutting. I may take this opportunity of stating that the large form of *Carex pendula* has been found in a variegated state, and is said to be a real gem. Single shoots of this beautiful *Carex* will be useful for the cool greenhouse and for decoration indoors. Where it can be well supplied with water it makes a beautiful pot plant. The following are the variegated Grasses to which I have just alluded, viz., *Anthoxanthum odoratum variegatum*, *Alopecurus pratensis argenteus striatus*, *Dactylis glomerata argentea striata* (a very large form), *D. g. tenuifolia*, with cream-coloured stripes, *D. g. aurea striata*, very striking. The above three varieties of *Dactylis* were found wild during the present summer. Other variegated Grasses are *Holcus lanatus aureus*, *H. mollis argenteus striatus* (new and strong form), *Holcus mollis*, yellow-striped, *Poa arvensis argentea*, *P. trivialis aurea striata*, *Phleum pratense argenteum striatum*, and *P. p. aureum striatum*. There are also several variegated Carices.—W. ELLIOTT, *Stockbridge*.

Ampelopsis Veitchi.—To get the full beauty of the fiery autumnal tints which this lovely creeper assumes, it should be planted in full exposure to sun and air. I have some under a glass-covered corridor, but the tints are not so rich as those on plants grown on open, exposed walls. It is one of those plants that are not improved by coddling under glass. I find the slender sprays very useful for decorative purposes, either in a green state or when changing colour. They do extremely well at this time of year for table decoration, as on a white cloth their colours show well under artificial light.—J. G. L.

A Beautiful Rock Plant.—A couple of years ago I saw a plant of one of the ordinary bedding *Lobelias* growing among rockwork, and in full luxuriance of foliage, and flowers, rolling over in small undulating masses, as attractive in habit as in colour—a perfect little "beauty of the rocks." It was self-sown, carried there probably among a friendly spadeful of earth from one of the flower beds near. I remember that plant to this day. In the spring of this year I purchased a book on "Alpine Flowers." Having made my rockwork according to the principles therein laid down, and having begged, borrowed, and bought all the suitable plants I could, I still found myself in the position of an individual with a large house and not enough furniture to put in it. However, I had plenty of *Lobelias* of different varieties of the *Erinus* section, and I dibbled them in among the stones wherever I could find room, and wherever I thought they would not interfere with the permanent residents. They have proved most effective during the whole of the past wet season, and even now (Nov. 4) are a sight to gladden the eyes. The compact kinds look best jammed in among pieces of stones, so as to destroy their stiff, geometrical appearance. The stragglers seem most at home drooping over a stone with a steep face, but anywhere and everywhere I can honestly recommend the *Lobelia* as a veritable first-class plant for rockwork. Many of the plants I used were seedlings, which varied very much; but then in rockwork variety is charming, and sameness to be avoided.—EDWIN JACKSON, *Llandegai*.

Tea Roses for Autumn Flowering.—Many have borne testimony to the fact that there has been a great wealth of Tea Roses this autumn. The Tea Rose is a fine autumn-blooming subject, and it can be managed so that there shall be no lack of flowers at any time. The plan adopted by Mr. S. J. Pavitt, of the Rose Cottage Nursery, Bathwick, Bath, is one that answers well. It may not lay claim to novelty, but it does greatly assist in the production of flowers at a time when they are most serviceable. Indeed, Mr. Pavitt asserts that while he can gather Roses for six months in the

year, any one with a little glass at their disposal can have Roses the whole of the year. Mr. Pavitt grows his Tea Roses on a border facing the east, which is protected by a belt of trees at the back, and forms a shelter from the westerly gales. He considers that it is wrong to plant Tea Roses on a south border, as in such a position, exposed as it is to the full power of the sun, the flowers get scorched up sometimes before they become fully expanded. When planted in an eastern border situated similarly to that in Mr. Pavitt's nursery, the plants get the morning sun only for a few hours, which is all they want in his opinion, and they are never exposed to the afternoon sun. This has an important bearing on the production of fine flowers and their preservation and continuity. The beds in which the Roses are planted are thoroughly trenched and prepared during the winter months, and in the month of May the plants, which are always worked on the seedling Brier, are put out into the prepared ground, and all the flowering buds are kept pinched off till the end of July, the result being that throughout the late summer and the autumn months, when the weather is favourable, there is quite a wonderful bloom. In case of very severe weather setting in and frost being imminent, a little common Fern stuck among the plants is found to give them all the protection necessary. Some thoroughly good autumn-flowering varieties of Tea Roses will be found in the following list:—Catherine Mermet, Devoniensis, Rubens, Madame Faleot, Madame Charles, Madame Camille, Madame Willermoz, Safrano, Isabella Sprunt, Goubault, and Mlle. Margottin. This list is not to be taken to the exclusion of other good sorts; it simply means that the varieties named have been found to answer well for the purpose. The provision of glass merely without the means of artificial heating will not do much in the way of the production of Roses during the winter. A Rose house is like a mine of wealth to a gardener, as according to the time when he commences to force will he reap—if the plants be well managed—an abundance of beautiful and useful flowers.—R. D.

Lobelia fulgens.—One of the most brilliant of flowering plants at this season is that fine hardy perennial, *Lobelia fulgens*. One rarely sees it in good condition, probably owing to the fact of its requirements not being sufficiently studied. It luxuriates, and will last in good condition for an indefinite period, in a free, porous, well-drained soil; but where the soil is naturally of a cold heavy description, the roots are liable to the attacks of a kind of canker. The plants succumb to the first period of inclement weather, and very often—much to the vexation and wonderment of the grower—altogether fail to show signs of growth the ensuing spring. The safest plan is, where any doubt exists upon the matter, to take the plants up as soon as they are done flowering, wash the roots, and lay them in in a free soil in a frame. They then immediately make fresh rootlets, and are thus ensured against decay. The situation chosen for planting should also be sheltered. No better place can be found than amongst evergreen shrubs, where there is plenty of light, air, and space for development. I recently saw a row of this *Lobelia* planted alternately with a bright variety of Phlox in front of a Laurel screen, the intense green of which admirably showed up the vivid glowing hues of these two flowering plants. The cold nights and damp days which we at this time of the year experience do not appear in the least to dim the beauty of this *Lobelia*, the flowers now produced being as fresh, highly-coloured, and well developed as those which expanded earlier in the season. Such plants as these which flower freely and brightly amongst the fogs and dark autumn days are very welcome, and are well deserving of some cultural care.—J. C., *Blyct*.

An Improved Flower Pot.—Mr. Peter Henderson recommends in the *American Agriculturist* a flower pot with holes low down in the side instead of in the bottom. We have, he says, during the past six months tried about a thousand, of sizes ranging from 3 in. to 6 in. in diameter, and find they are all we expected of them. All cultivators know the difficulty experienced when the ordinary flower pot is placed on a bench covered with sand or soil—the outlet often becomes completely closed by the washing of the soil through the outlet, and, being closed by the sand, the drainage becomes stopped as completely as if there was no orifice at all in the bottom of the pot. Again, worms breed quickly in the sand or soil, and seem to take a special pleasure in crawling under and through the holes in the bottom of the pots, to get at the rich soil which they contain. This improved pot is safe from the first difficulty, as the holes, being on the sides of the pot, cannot be clogged by the sand; while it is far less tempting to the worm, as a special effort must be made before the hole can be reached. Still another advantage, and we think a very important one, is that as these orifices are placed above the bottom, air is admitted more freely to the roots, a matter which is very essential to the well-being of plants. I have but little doubt that if this style of flower pot can be as cheaply made, that it will quite throw the old style out of use.

NOTES OF THE WEEK.

The Cranberry Pippin.—This beautiful American Apple may now be seen in Covent Garden. It has a fine juicy flavour; in fact, as good as that of Newtown Pippins of ordinary quality. In "Downing" it is described as a beautiful Apple, but "second-rate in point of flavour, and an excellent cooking and market Apple"—a remark which suggests how good Apples must be where this is second-rate.

Crawfurdia speciosa.—This, one of the few of the twining species of Gentianaceous plants, is showing flowers at Kew, where it is trailing over some branches placed against one of the walls out-of-doors. Its flowers are said to be large and handsome, and no doubt they are if of the fine blue colour which prevails in the genus. The stems are slender, and the dark green leaves are somewhat heart-shaped in form and pointed. It inhabits high mountainous districts in Northern India, about Sikkim and elsewhere, and, therefore, may be expected to prove quite hardy in our climate.

Fuchsia dependens.—In one of the houses at Chiswick this rare and pretty species is now in flower. It is somewhat similar in habit to the better known *F. corymbiflora*, and, like it, bears pendulous clusters of flowers, which render it very showy when plentifully produced. The blossoms of *F. dependens* are about 2 in. long, with a narrow tube of a soft scarlet hue; this, with the petals, which are of a brighter tint, form an agreeable contrast. This, and several other species of a like habit of growth, are trained near the roof, a position in which they have a very graceful appearance. This species was found several years ago on the northern slope of Pinchincha, near Quito, by the late Dr. Jamieson, and was by him sent to this country.

Chamædorea glaucifolia.—This extremely graceful Palm is now an object of much attraction in the Aroid house at Kew, where it is producing several elegant drooping clusters of flowers. The leaves, which are long and arching, consist of long, narrow pinnae, which are disposed without any definite arrangement, and hang loosely from the midrib, and their glaucous hue considerably increases their effect. One objection to this Palm is that it attains a great height in a comparatively short space of time; thus its head of foliage is not seen to advantage, but when in a dwarf state few more elegant Palms could be found. Like most of its congeners it is a native of tropical South America, and is found plentifully in the region of Columbia.

Dyckia frigida.—A specimen of this handsome Bromeliad has for some time past been an ornament to the cooler portion of the Succulent house at Kew. It has a large, dense head of long, coarsely-toothed leaves, the surfaces of which are overlaid with a white, wool-like substance. From the centre of the tuft is produced a tall, branching flower-stem bearing a large number of deep orange-red flowers about $\frac{3}{4}$ in. long. Like many of its congeners it is a native of South Brazil. In the same house is a fine example of another Bromeliaceous plant (*Pitcairnea ferruginea*), a native of Peru, bearing a huge panicle of velvety-brown flowers.

Billbergia Moreli.—This Bromeliad is one of the most beautiful, as well as the showiest of all the cultivated Billbergias. It is now in great beauty in Messrs. Henderson's nursery at Maida Vale. The foliage, which is bright green, forms a fine contrast to the rich scarlet bracts which clothe the flower-spike. Its flowers are about 2 in. long, bright scarlet in the lower half, and rich purple at the tip, and they terminate the gracefully-drooping spike. Another handsome species, also very attractive just now, is *B. thyrsoidea*, which has similar scarlet bracts on the spike, but which is quite erect, and the flowers are longer and lack the purple tips of those in the other kind. The above are both natives of Brazil. There are several other beautiful Bromeliaceous plants also in flower in the same house, such as *Vriesia speciosa*, with a brilliant scarlet flower-spike 2 ft. long, and yellow blossoms, which are admirably set off by the singular zebra-striped foliage. The sight of these exotics at once suggests the enquiry as to why their culture is so much neglected in gardens generally, seeing that many of them rival, if not surpass, in brilliancy of hues the choicest of Orchids.

Autumn Flowering Crocuses.—The display of these at Kew this season has been moderate, owing no doubt to the frequent transplanting to which they have been subjected, and which is evidently highly detrimental to their well-being. There are, however, several pretty species in flower, comprising, besides the well-known *C. speciosus*, *C. nudiflorus*, *C. byzantinus*, *C. pulchellus*, *C. medius*, *C. Clusii*, &c., such rarely-met-with kinds as *C. Kotschyanus*, a beautiful species from Asia Minor, with flowers having the same pale lilac tint and white anthers as *C. pulchellus*, but much larger, and, in addition, a conspicuous ring of yellow at the inner base of the flower, from which character its synonym, *C. zonatus*, was given. The rare *C. hadriaticus* is also in flower; its blossoms are white

with faint dashes of a slaty tinge on the outer base. *C. Salzmanni*, which is considered by some to be a variety of *C. serotinus*, is one of the most desirable, as it possesses the character of producing flowers and foliage at the same time; thus the naked appearance which the other kinds have is obviated. One of Mr. Maw's late introductions is likewise in flower. The label denotes that it has not before been introduced, and, judging from the appearance of the partially withered flowers, it will be an acquisition, as they are large and bright in colour.

Crassula alpestris.—On the rockery at Chiswick this new succulent plant is still in flower, having first expanded several months ago. It is a very pretty neat-habited kind with slender trailing stems, which earlier in the season, are bright red, and are terminated by a cluster about 1 in. across of small waxy-white blossoms, the stamens of which are red, thus affording a pleasing contrast to the flowers. It is presumably quite hardy, though none of the other species are. It is a native of the Cape of Good Hope, and was first received at Kew about a year ago from Mr. Max Leichtlin, of Baden-Baden, under the name of *Sedum alpestre*.

Parrotia persica.—Foremost as regards autumnal-tinted beauty is this rare Persian tree, which against walls, and even planted as isolated specimens on the lawns at Kew, is now highly attractive. Few trees possess decaying leaves so richly tinted as these, varying, as they do, from a bright golden hue to the deepest crimson. In habit and general appearance it reminds one of a Beech tree, but it belongs to a widely different family. Its flowers are inconspicuous, and rarely produced in this country; but it is well worth a place anywhere for its autumn-tinted leaves alone. It is scarce in gardens, a circumstance doubtless owing to the difficulty of its propagation. The Liquidambar, too, are very conspicuous at Kew, though much less so than we have seen them in other seasons.

Catleya labiata.—The true old variety of this plant is now bearing eight large and richly coloured flowers on two stout spikes in the Trinity College Gardens, Dublin. *Odontoglossum grande*, the snow-white *Pilumna fragrans*, and a healthy specimen of Selen's rosy-flowered Lady's Slipper (*Cypripedium Sedeni*)—one of the best of the hybrid varieties—are also now very effective at the same place.

Geonoma Seemanni.—This Palm, though at all times handsome, is most attractive when bearing a number of its singularly forked clusters of flower-spikes, which are produced from the axils of the broad arching leaves. We saw it in this condition a few days ago in Mr. Williams' nursery at Holloway, where there is a fine specimen of it from 6 ft. to 7 ft. in height.

Tyerman's Groundsel.—A good specimen of this plant nearly 3 ft. high, and in vigorous health, is now bearing a dozen fully expanded flowers and many buds in a border in the Trinity College Botanical Gardens, Dublin. Each individual flower is 3 in. across, of a bright magenta purple, with a conspicuous golden disk. Bees are very fond of resting on the flowers for the sake of the nectar or pollen supply which they afford. Well developed specimens of this plant are very showy in the flower garden at this late season, and until very recently the white flowered *Pyrethrum uliginosum* has borne them company. A quantity of this *Senecio* grown on a warm sheltered border would be very useful for indoor or for cool conservatory decoration if carefully lifted, and potted as soon as the flower buds appeared. In this way the plants might possibly ripen seed, which they rarely have a chance of doing in the open border. Few plants are more easily increased. Cuttings of the roots, 1 in. long, sown like seeds in a pan of light sandy earth, soon develop buds in a cool frame or on a shelf in the greenhouse.—W.

THE INDOOR GARDEN.

COOL SYSTEM OF FLOWERING BOUVDARDIAS.

I WAS, I believe, the first to point out in THE GARDEN that the Bouvardia could be grown as successfully, or perhaps better, under cool treatment than in heat, though probably others had adopted the system as soon as myself. The correspondence in THE GARDEN now shows that the cool system is finding most favour, and the advocates of warm treatment are not likely to arrest progress in that direction, unless they have something more than assertions to offer in support of their views. It is stated (p. 390) that Bouvardias "bloom after a fashion" under cool treatment. If this means that they cannot be so grown quite as successfully, to say the least, as by the system recommended about two years ago in the "Gardeners' Assistant," then I venture to say that the author of the above assertion never saw a really good cool-grown Bouvardia, and does not know what can be accomplished by such treatment.

In the book above mentioned cuttings are recommended to be struck in April, and after they are potted to be kept in a night temperature of 70°, with a rise of 10° by day. This practice is to be continued "till the end of July," when the plants are to be removed to a cool frame, where they are to remain till the middle of September (a time at which they are flowering out-of-doors here); but "if flowers are required through the autumn, a portion of the plants should at once be placed in a temperature of 68° or 70° at night, with a few degrees higher in the day time." If this is not stove treatment, pure and simple, I do not know what it can be called. Is Mr. Baines prepared to name a single market grower who prepares his Bouvardias for the stalls in Covent Garden in this way in winter? In THE GARDEN last year one nurseryman was named who grew several thousands for market on the cool system, and no doubt plenty of others follow his example. The market gardener is not the man to buy coals in London to grow Bouvardias in heat all the year round, when he can do without them. From Mr. Baines' admission last week that he only now recommends heat for those plants to bloom "during the two last months of the year," I take it that he has abandoned the ideas which he expressed in the "Gardeners' Assistant," and that being so, he can well afford to abandon the rest. The assertion that cool-grown plants produce flowers deficient in colour, or that are unsalable in the market, is disproved by facts. The finest plants and flowers I ever saw anywhere, including Covent Garden, were grown in front of a Beech hedge during the summer at Handsworth, and were at their best in Christmas week of the same year.

J. S. W.

Fuchsia boliviana.—When looking through the large collection of Fuchsias at Swanley the other day, I was much impressed with the fine appearance of this species. It has large handsome foliage, and is of a very vigorous, but at the same time compact, branching habit, producing an abundance of richly-coloured flowers, some 3 in. in length. It is a highly ornamental and very distinct kind, well worth the attention of lovers of this family of flowering plants. Large specimens of it would undoubtedly prove very effective for conservatory decoration.—J. C., *Byfleet*.

The Last New Australian Palm (*Areca Alice*) has been dedicated by Baron Mueller, in the *Gartenflora*, to the memory of the late Princess Alice, Grand Duchess of Hesse. It was discovered by the indefatigable Mr. Walter Hill in north-east Australia, about ten miles north of Trinity Bay, and transferred by him to the Brisbane Botanic Garden, where it has flowered and fruited. This new Palm will prove a welcome addition to our limited number of species suitable for small houses, inasmuch as it grows only about 10 ft. high, and throws up several stems from the same root. The pinnately divided leaves are about 5 ft. long, and the slender stems 1 in. to 2 in. thick. *Areca Alice* is allied to *A. oxycarpa*, a native of the Celebes, and *A. triandra*, of the Malay Peninsula, Java, and neighbouring islands. We are not aware that this Palm has yet been introduced into European gardens; but if it has not, it doubtless soon will be, now that it has fruited under cultivation.—*Florist*.

Myosotis dissitiflora for Winter Flowering.—This is very much appreciated here during the dark days of winter, and as it can be had by any one possessing an ordinary greenhouse, it is to be regretted that it is not oftener seen than it is. To get up a stock of plants for this purpose, it is only necessary to pull the requisite number of pieces off old plants, and insert them in ordinary soil on a shady border about the beginning of August. Seeds sown about the end of June will furnish plants equally suitable. Cuttings strike root without any particular care, and if put in at the time and in the manner indicated, will become plants ready for potting off about the beginning of October. We use 4½-in. and 5-in. pots, and in potting, take any potting soil handy. When lifted with good balls, they never know that they have been moved. After they have stood in the shade for a day or two, we place them in an ordinary frame on a dry site, and here they are treated to all the air they can get in all weather, lights only being used for the purpose of keeping off heavy rains. As they root rapidly the pots soon fill with them, and care is taken to prevent them flagging from want of water; otherwise they are kept as dry as possible, and this tends to make them free-flowering. In ordinary mild winters they will bloom in the frames, and in any case are sure to do so very early in spring. To have Forget-me-nots all winter is, however, the easiest task imaginable, and all that is wanted in the way of forcing is to bring in a few pots at a time into any house kept at greenhouse temperature, when they will throw up their trusses in a week or two, and continue blooming for a long time.—"The Gardener."

Alpine Flowers for English Gardens.—Mr. Murray has published a third and cheaper edition of this book. In printing, illustrations, &c., it is in all respects as good as the previous one. The price of the new edition is 7s. 6d.

PLATE CCV.

BLETIA HYACINTHINA.

Drawn by CONSTANCE PIERREPONT.

ANY addition to the list of beautiful exotics which may be treated as hardy plants in our climate must be considered a welcome acquisition. The plant of which we give an illustration this week is an Orchid that has for many years been grown under glass as a tender plant, and it is only recently that any account of its hardiness has reached us. Mr. A. E. Barnaart, of Haarlem, brought a plant of it in flower to THE GARDEN Office a few months ago, from his nursery, that had proved hardy with him several years, and from this plant our plate was prepared. Since then we have had corroborative evidence of its hardiness from various sources, and we saw some plants of it the other day in Mr. G. F. Wilson's wild garden near Weybridge. This had been planted out for some considerable time, and was in most vigorous health—in fact, more robust than plants grown under glass generally are. Mr. Wilson's plants are growing in the soil natural to the place, which is a deep moist mass of decayed vegetable mould, which doubtless has been accumulating there for ages. As to its beauty when in flower a glance at the accompanying plate is sufficient proof. The shade of colour, however, is somewhat darker than that seen in the typical specimens, thereby justifying the varietal name which was appended to the plant received from our Dutch correspondent, which was *B. japonica purpurea*. As *B. japonica* is but a garden name for *B. hyacinthina*, the latter name must have precedence. It is a native of China, and like many other plants of that country, has doubtless been sent from the neighbouring country, Japan, which probably has given origin to the name *B. japonica*.

W. G.

Alpine Plants and Rockeries.—From Mr. Williams' remarks (p. 370) in reference to this subject, one would be led to infer that in my note (p. 344) in connection with the rockery at York, I had endeavoured to convey the idea that the culture of Alpine plants is beset with difficulties both imaginary and real, and that such subjects cannot be grown successfully except upon such elaborate and extensive structures as the rockery in question. By turning to my remarks, however, he will see that I stated that it would be impracticable in the majority of instances to imitate the York rockery as regards extent, but that the *principle* of construction was identical both in large and small rockeries, and that Mr. Backhouse's rockery might be profitably studied as an example of the correct way in adjusting the material used in its construction and the disposition of the plants. That there is a good deal of unnecessary "fuss" made about growing Alpine plants cannot be denied; but why is that the case? simply because in nine cases out of ten they are not placed at first under the necessary conditions for ultimate success. The plants thus circumstanced drag out a miserable existence, and so are considered unmanageable, the result being that any renewed attempt at Alpine plant culture in such cases is abandoned. Unfortunately the prevailing idea of a rockery is a mass of stones or other material so arranged that it has a more or less rustic appearance, and what should be the primary consideration is in most cases ignored—which is to afford a moist medium for the roots in dry weather, and drainage and a dry surface in winter. That a large number of Alpine plants may be grown well without any rockery at all is a well-known fact, if the term Alpine is understood in its widest meaning; but by far the largest number, and these comprise some of the most beautiful, of what are generally termed Alpines, are not only benefited by being grown on well-constructed rockwork, but will absolutely refuse to thrive satisfactorily if grown in an ordinary border. Besides, there are other disadvantages attending this plan of growing them; for instance, being so dwarf it is necessary, in order to inspect them conveniently and thereby form an adequate idea of their beauty, to either stoop considerably or fall on one's hands and knees; whereas, when placed on raised rockwork they are brought more on a level with the eye, and are thus more conveniently seen. Other disadvantages are, that they are apt to become over-run by larger-growing subjects, or if these are not grown along with them the beds present monotonous flatness throughout the year; and, moreover, they are in this position an easier prey to slugs, &c. I should be sorry, indeed, if my description of the York rockery was in any way calculated to cause persons to abandon any attempt at the growth of Alpines for ever as Mr. Williams puts it; but I think there is little to fear in this respect, or the trade in these plants would not be so extensive as it now is, and it seems to me greatly to be increased, thereby showing that the taste for Alpine plant-growing is becoming year by year more popular instead of less so.—WILLIAM GOLDRING.

A HARDY ORCHID (BLETIA HYACINTHINA)

GARDENING FOR THE WEEK.

Greenhouse.

Azaleas.—The length of time during which these plants may be had in flower has induced many growers to vary their treatment so as to, if not have them in for the full period possible, so regulate their flowering as to very much prolong their season, instead of the course which used to be pursued of letting them come in in a great measure through the influence of sun heat during April and May. Such plants as were purposely retarded to bloom late should now have completed their growth and formed flower-buds; but in many places, through an absence of sun, the growth has been so late and backward that the buds are far from possessing that character which it is desirable they should do; but it is now too late to remedy the evil, and I simply allude to the matter in order to recommend those who find their plants in this condition to take note, so as to avoid a like state for the time to come when such summers as this occur; for so manageable are these plants, that wherever there is a deficiency of sun to bring on the growth of the late blooming portion of the stock, and get it properly matured and ripened up before the autumn is too far advanced, this can always be remedied by the use of fire-heat. Unless this essential condition in the season's growth is present, it is useless to look for large, fully developed flowers, although the plants may produce a sufficient number; through this cause it frequently happens that in the coldest, least sunny districts in the north of the kingdom, where Azaleas will rarely succeed as they ought to do without some fire-heat during the summer, a knowledge of this necessity often results in their being better managed than in the more favoured south. Plants that have been hitherto the earliest forced should at once be put into heat, but in no case ought they to be hurried by submitting them to too much warmth, or allowed to stand far from the glass overcrowded with other plants, or under any influence that subjects them to an insufficiency of light, as either of these has a direct tendency to shorten the duration of the flowers.

Winter-flowering Heaths.—Where a sufficient stock of the different varieties of these exists, they play an important part in conservatory decoration for some months during the dull season. We often hear complaints made by those who annually buy in a stock of these winter-blooming Heaths, that they are very liable to die off towards spring; this may in some measure be due to the treatment they have received at the hands of the growers with a view to give the plants a vigorous, luxuriant appearance; but it also is often caused by their being submitted to usage that no members of the Heath family would bear, that is, being crowded together amongst other plants, where they labour under a deficiency of air and light, two elements of greater importance to Heaths in general than to most other families of plants. Neither can they bear keeping too warm, and where greenhouses are kept through the winter—as with many—at a temperature of 45° in the night, Heaths of the above description are sure to suffer unless they are all but touching the glass in the lightest pits or houses it is possible to erect. The luxuriant, profusely flowered condition that well managed plants of this character have when sent out by those who grow them largely for sale, is simply the result of two or three years' high and careful cultivation; the balls of earth the pots contain are complete masses of densely packed roots that, if ever allowed to suffer from want of water, are sure to be so affected as to cause their almost certain destruction. This points to the necessity for continued watchfulness as to their requirements for water, and where there is an inclination to do anything with them beyond simply flowering and then discarding them, as is generally done with Hyacinths, constant attention to their wants is indispensable. The more than usual soft condition of the foliage, which has been formed during an all but continuance of dull weather, will make them more than ordinarily subject to mildew, which if only once existent spreads apace. The stock should be looked over every ten days, and where the slightest trace of this parasite can be found the plant should be dusted with flowers of sulphur or syringed with water impregnated with sulphur; where either are used it is necessary to be particularly careful that neither the sulphur nor the water in which it is held in solution gets to the roots.

Lachenalias.—There exist many more varieties of these than are generally known, the flowers of which range from white, rose, orange, red, and yellow, to the colours of the well-known *L. tricolor*, with its combination of red, yellow, and green. Where a sufficient number of plants are grown they may be had in flower over a lengthened period by forcing some, allowing others to come on in an ordinary greenhouse, and retarding another portion in cold frames, with just as much protection through the winter as will keep them from being frozen during hard weather; for though nearly hardy it is better not to let the frost reach them. I have found the following varieties very useful, viz., *L. fragrans*, the flowers of which are

red and white, sweet-scented; *L. pustulata* violacea, violet; *L. quadricolor*, orange, red, and yellow; *L. tigrina*, white; *L. tricolor*, one of the freest bloomers, coming in early; *L. pendula*, red, tipped with yellow and green; this with me grew stronger than most of the others. There are several more, but these fairly represent the family.

Chrysanthemums.—These, where not already indoors, or under protection of some kind, should at once be got in. Now, when the buds are considerably developed, the plants collectively are less liable to receive injury, even when put with ordinary greenhouse stock, than when only just about formed. Wherever they are placed give them as much air as can be admitted with a due regard to the other plants associated with them. Where some of the latest-flowering kinds are grown with a view to keeping them back as late as possible, there will be no difficulty in doing so where there is a house with a north aspect with a full volume of air night and day, except where there is an appearance of frost. These will not open their flowers before the latter part of December, when, if the buds are well thinned, and all suckers kept removed from the base of the plants, they will be alike useful for general decoration and cutting.

Eurya latifolia variegata.—There is not a greenhouse in the country, large or small, into which this plant might not be introduced with advantage. Its handsome leaves—about the size of those of an Orange—are richly variegated with creamy white. It is a good grower, and has an equally pleasing appearance in a small and in a large state. Though nearly hardy on a wall in the south of the kingdom, it seems most at home as a greenhouse plant. It is now cheap enough, and is easily propagated; points of the shoots of this summer's growth taken off now with three or four joints, and placed in a cold pit or house covered with bell-glasses and kept moist, will have their base well callused over in the course of three months, when, if put into a little heat, they will root immediately; they can then in the spring be potted off and grown on. They will do duty in greenhouses and conservatories, in no way inferior to that which the *Crotons* do in the stove.

Euonymuses.—Although these are quite hardy in most parts of the country, and the majority of them ultimately grow to a large size, they are amongst the most useful plants for pot culture that can be grown, especially the variegated kinds; the ease with which they can be propagated and grown admits of their being used in quantity for decorative purposes in halls, porches, verandahs, and window-boxes for the winter, in all of which positions their bright, handsome foliage almost supplies the place of flowers. Cuttings taken off now made of the young shoots and inserted thickly in pots plunged in ashes and kept in cold frames through the winter, just protected from frost, will root in the spring with or without artificial warmth, but if assisted with a slight hot-bed then it will much help the season's growth. When well rooted they should be planted out in rows in well prepared free soil in a light situation, in which, by the end of the second summer, they will have made good bushy plants ready for potting off. Any of the erect-growing variegated forms are suitable for the uses here recommended.

Shrubs for Forcing.—These, which may now be taken up, should include *Rhododendrons*, selecting for the purpose the early blooming kinds; many *Rhododendrons* naturally bloom too soon in the season to admit of their having a reasonable chance of escaping frost in the open air, and on this account numbers of sorts which have this habit have been discarded; whereas, if they had been grown extensively for pot culture, they would have supplied, with glass protection only through the later portion of winter and spring, flowers for conservatory decoration of a most useful character. Where large quantities of blooming plants are needed few things would be more effective or economical, and if a piece of reserve ground was devoted to them, so as to admit of their propagation in sufficient numbers, and in which the plants that have bloomed could be turned out after flowering, this would allow each year those being used best furnished with flower-buds. Quite equal to the above class of *Rhododendrons* are the Japanese varieties of *Azalea mollis*, which are great improvements in size and substance on the Ghent sorts; they, too, turn out to be better adapted for using as pot plants in this way than for blooming out-of-doors, as, except in the most favoured localities, they have a disposition to flower before danger from spring frosts is over. The hardy *Azalea* (*A. amena*) and the Ghent varieties are excellent forcers. *Kalmia latifolia*, *Laurus tinus*, the double-flowered *Prunus*, *Deutzia gracilis*, *Lilacs*, and the Guelder Rose all answer well for this purpose, and are very serviceable in helping the supply of ordinary greenhouse plants. They are especially to be recommended where the means at command in the shape of houses and pits solely devoted to plant-growing is insufficient to keep up the requisite supply, as in many places during the winter season there are mid-season and late Vineries and Peach-houses, where such plants can be placed out of the reach of frost and snow, and where they will be slightly

encouraged to come on into bloom, and be in a better condition for introducing to the forcing-house than if left out in the open air.—T. BAINES.

Flower Garden.

Carnations and Picotees.—See that all newly-potted plants are kept moist at the roots as soon as new rootlets are formed, and the frame light should be rather more tilted as the plants seem to become established. In a fortnight or so after potting, the lights, when the weather is fine, may be removed altogether. I always fumigate the plants after they are established, as a preventive of green fly. There are several methods of fumigating low frames, but the plan which we practise here is the simplest which I have yet tried. A square hole is dug in the ground, half of it under and half of it outside the frame, and deep enough to hold the fumigator. The latter is merely a cylinder made of sheet iron, with a grating at bottom; it is about 7 in. wide and 1 ft. deep. Some burning coal or coke from a neighbouring furnace is placed in the bottom, and over it is laid the Tobacco or Tobacco-paper. The apparatus thus arranged is dropped into the outside hole, and pushed quite under the frame. When the latter is sufficiently filled, the fumigator is pulled out, and a sack or mat is placed over the hole. I much prefer destroying the fly after it does appear by fumigating; but in the case of a small number of plants they may be dipped in soft-soapy water sufficiently strong to kill it.

Dahlias.—We have not yet taken the roots up, although 4° of frost have quite blackened the leaves and spoiled the flowers. We will allow them to remain until the weather shows signs of breaking. At present it is cold, but no signs of frost or rain have presented themselves since the Dahlias were killed on the evening of October 25. There is no difficulty with us in getting the roots dried, as they can be taken into any of the Vineries from which the Grapes have been cut. The roots while in the ground will still continue to mature, as the leaves are not all blackened; some are even yet quite green, and the stems are sound. While the weather is still favourable, the ground should be prepared for next year. Even if the soil is rich it will not do to trust to only digging it over. It will be necessary to trench it 2 ft. deep or more, working into it plenty of good manure. The best for this purpose is to obtain, if possible, equal quantities from the cow-sheds and stables; throw the two up into a heap, mixing them well; turn them over twice at intervals of a week, and in a month it is ready for use. A word here on trenching: Workmen may frequently be seen trenching a piece of ground that has been trodden hard; they throw the lumps of soil just as they move them into the bottom of the trench. Where the soil is heavy this is very bad management, and such a loose style of trenching is to be deprecated under any circumstances. Choose a fine day, when the soil is rather dry, to fork the surface over, breaking up the lumps well. In a week or ten days after this has been done the ground may be trenched. Thus treated, a loose dry soil will be placed in the bottom instead of hard lumps, which, even if they are broken up as thrown in, have not been submitted to the ameliorating effects of the atmosphere.

Gladioli.—We lifted our roots of these immediately after the first occurrence of frost, as the flowers were quite useless for this season. The corns are certainly in very bad condition, being small and unripened. Such as they are they have been laid out as usual on the floor in one of the Vineries to dry. The ground for next year ought now to be trenched, according to the plan laid down in THE GARDEN (p. 374); in fact, I like the soil to be exposed for Gladioli as early as September, and if the place where they are to be planted next year can be trenched at that time, and the surface be frequently forked over, so much the better. Seedlings that have been grown in pots all the summer should now be turned out of them. The small bulbs should be carefully picked out from amongst the soil; they may then be put into paper bags amongst a little dry sand.

Phloxes, Delphiniums, Pyrethrums, &c.—These have now assumed the sere and yellow leaf. The stems must all be cut over close to the ground. Stir the surface soil well up, and keep the beds and borders free from weeds.

Tulips.—If the soil is in good condition these should be planted next week. It is always best to have some good fibrous loam under cover to place on the surface of the beds; this should be free from manure, but the soil should be rather rich underneath. An old author says, "The Tulip asketh a rich soil, and the careful hand of the gardener." When the beds are ready begin to plant at once, making a hole with a small trowel, and putting in a little fine dry sand, then the bulb, and over it a little more sand; then cover all with loam to the depth of 2 in.

Hardy Cypripediums.—These are now, to all appearance, at rest, but on examination it will be found that the roots are growing, and that the stem for next season is in an incipient state. Now

is the time to repot them. I shake all the soil from the roots, fill clean pots half-full of potsherds, and then repot in equal portions of fibrous loam and fibrous peat, mixing some bits of charcoal amongst it. Plant a little Sphagnum on the surface, and if this is just kept in a growing state during winter that will afford sufficient moisture.—J. DOUGLAS.

Indoor Fruit.

Vines.—Late-planted young Vines that have grown vigorously, as they generally do, will still require artificial warmth in combination with free ventilation, in order to ensure thorough ripeness of wood. Even in the best of seasons, it is sometimes difficult to get such Vines to ripen, and as the present one has been all but useless, it will at once be seen how necessary a continuation of artificial warmth is. Such Vines may now have the growth that was allowed to run, to induce greater root-action, cut off; but in its removal carefully guard against injury to the foliage on the main stem, that being an important factor in the plumping up of the fruit-buds. Late Grapes, particularly Lady Downes, will still be the better for having the temperature kept up to about 65°, and the surplus growth on these should also now be removed, as light and air are essential as regards the good preservation of the fruit so long as it remains on the Vines. Grapes that have been ripe for some time, and which are keeping but indifferently on the Vines, through the surroundings being damp, ought to be cut and placed in bottles, as recommended in THE GARDEN (p. 374). In the case of Grapes that are to be ripe in April, or early in May, the Vines will at once require to be started. "Slow and sure" should be the motto, so for the present be content with keeping the house closed without applying fire-heat. Prior to starting, see that the inside borders are well moistened through with water at a temperature of 80° or 90°, and outside borders should have a thick covering of litter or bracken put on them to exclude frost, and shutters or tarpaulin to throw off wet. If, as is in many instances the case, the earliest Grapes are had from pot Vines, these too should be now started, and, though bottom-heat is not essential, a slight warmth, such as that produced by 2 ft. or 3 ft. in thickness of Oak leaves, will assist the earlier starting of the Vines; and even if allowed to root into the leaves, as they will do as the heat declines, such rooting is beneficial.

Figs.—The earliest trees in pots should now be got in readiness for starting in gentle warmth. There will probably this season be few trees in a fit condition for this yet, and so long as a doubt exists in the matter it will be advisable to give the trees the benefit of it; for though later in starting, ultimately those that have had the longest rest will win the race both as to time and results. Planted-out trees will now have lost their foliage, and should therefore be untied from the trellis; all naked and unnecessary wood should be cut out, and if insects have been troublesome, the trees should be well washed with soapy water and afterwards painted over either with a mixture of Gishurst Compound (4 oz. to the gallon of water), or with a strong solution of soft soap, sulphur, and Tobacco water. We have been much troubled with a small white scale, but last season we managed to eradicate it by thus cleansing the trees. If such an operation be thought necessary, now is the best time to check growth by root-pruning. All Figs do best in a contracted root space, and in that case root-pruning is rarely necessary after the first or second season of planting. The soil in which the Fig delights is a calcareous loam of moderate texture, with the addition of charcoal, lime scraps, and ½-in. bones. As soon as the trees have been cleansed, let the borders be top-dressed with the compost just named, of course having previously removed the old mulching and inert surface soil. The house should then be kept as cool as possible so long as frost is excluded, as the admission of this would prove injurious to the embryo fruit.

Peaches and Nectarines.—Early houses should still have full ventilation during the day, but they should be closed at night, for the buds are now so prominent that frost would prove injurious to them. As soon as the leaves are off the trees in succession houses unfasten them from the trellis, thin out the most naked shoots, and wash the trees with soapy water as a preventive against insects, or, if they have been infested with any during the past season, paint every tree entirely over with a strong soft soap lather, to which should be added a moderate proportion of sulphur and clay to thicken it. Gishurst is an excellent insecticide for such a dressing, the only danger lies in its being used too strong. If this be used, 4 oz. to the gallon of water should never be exceeded. The inexperienced would be safest to use only soft soap, the strongest solution of which does not harm the buds. All the glass and woodwork should be well scrubbed, and the walls lime-washed, both to destroy insects and make the house as light as possible. When retying the trees to the trellis, avoid laying them in too thickly; there should be at least 4 in. clear space between each shoot. Overcrowding the trellis with wood is a very common error, and difficult to overcome, as

whilst the trees are leafless we are apt to think that shoots tied in at that distance apart look very thin. The foliage in late houses, being ready to fall, should be assisted by a good shake of the trellis, or a gentle sweep upwards with a soft broom, and as soon as all the leaves are down, top-dress and root-prune after the manner recommended in previous notes in reference to early houses.—W. W.

Kitchen Garden.

In the majority of gardens work that could not be put off, such as root storing and the planting of crops, will now be completed, and attention can, therefore, be given to getting all vacant ground either dug, ridged, or trenched as the case may be. There is a general agreement amongst gardeners respecting the value of deep tilth for every variety of soil and crop, and it is only the question of insufficient labour in most gardens that hinders the practice of trenching from becoming more general and more frequently done. Soils vary so much, for whilst some are benefited by annual trenchings, others prove more productive if trenched only at intervals of two or three years. As a general rule, all kinds of light soils will pay for trenching annually, and the extra labour expended in doing it is saved by freedom from weeds in summer, and the ease with which the crops can be sown, hoed, earthened, &c. The trenching of heavy soils is a more formidable matter, but, as a set-off to this, it is not so frequently necessary. When it is done there should always be worked in with it a large amount of cinder ashes, lime scraps, or any material likely to render it more open and porous. Clayey soils are much improved by the addition of burnt soil, and whenever there is likely to be any fallow, advantage should be taken of it to burn a portion, which is easily done by collecting on the ground a heap of brushwood, hedge clippings, or a few faggots, in fact, anything that will create a body of fire wherewith to start the soil. Burnt earth for all adhesive soils is simply invaluable. The present is also as suitable—and, as there is no work particularly pressing just now, perhaps as convenient—a time as any during the whole year for clearing up soil-yards, rubbish heaps, and vegetable refuse of every description, all of which gives profitable employment for frosty mornings. Take advantage of dry weather to finally earth up Celery, and bracken or long litter should be in readiness for protection; for if severe frost sets in it will soon be seriously injured, as, like all other vegetable crops this season, there is a want of solidity and ripeness through lack of sunshine. Cauliflowers and the earliest Broccoli will need to be examined daily for the purpose of bending the leaves over the foliage to prevent injury from frost. Surplus heads can be retarded both by partial lifting (a gentle heave with a fork), or by entirely removing them to a cold shed. Cauliflower plants that are to be wintered in frames or hand-lights must still have the fullest exposure to the weather; the lights should only be put on when sharp frost appears certain. Slugs may be kept from injuring them by an occasional dusting with fresh lime, wood ashes, or soil. Lettuces, Endive, and other saladings intended for winter use will now all need partial protection, such as that afforded by cold pits, orchard houses, or hand-lights. Forcing operations must now begin in earnest: Asparagus, Seakale, and Rhubarb will now force freely, but they will doubtless require more time than usual, seeing that the roots were so late in maturing their growth. Herbs of all kinds usually asked for in winter can be had by planting a few roots in pots, and placing them in any house having a minimum temperature of 45°.—W. W.

Extracts from my Diary.—November 10 to 15.

FLOWERS.—Cutting back and placing Pelargoniums thickly in boxes. Staking Poinsettias. Looking over first batch of bulbs in ashes outside, and placing the most forward in frames. Placing Deutzias and Dielytras in gentle heat to start them. Placing Spiræas, Prunuses, and Violets in heat.

FRUIT.—Preparing place for banking Strawberries for the winter. Tying Raspberry canes. Painting Peach trees, and keeping first house close in order to start it. Packing Apples in boxes, wrapping each fruit separately in paper, and placing the boxes in a cellar to keep the fruit till May. Tying Peaches in early house. Looking over late Vines and cutting out superfluous wood to admit light. Placing first batch of Strawberries in cold frames on a south border for early forcing.

VEGETABLES.—Sowing on south border William the First, Omar Pasha (Gilbert's), Ringleader, and Laxton's Unique Peas, dressing them with red lead previous to sowing. Tying and thinning Tomatoes growing in Pine stoves. Manuring ground and turning it up rough to lie fallow during the winter. Potting Osborn's French Beans, and erecting a stage for them in Pine stove. Preparing pit for Asparagus. Soiling Mushroom bed in house, and turning manure ready for more beds. Tying and thinning winter Cucumbers. Strewing Lettuces and Endive with a slight covering of Fern for protection from frost. Covering up heaps of Carrots, Beet, and Turnips. Get-

ting Asparagus into frames for forcing, and covering them up with Fern to start it. Placing pots over first bed of Seakale.—R. G., *Burghley.*

TREES, SHRUBS, AND WOODLANDS.

THE CISTUSES OR ROCK ROSES.

Of the long list of species which compose this genus of beautiful flowering evergreen shrubs, comparatively few have been found sufficiently hardy for open-air cultivation in Britain, and even these require the shelter of a wall to enable them to survive the rigours of our ordinary winters. The great bulk of the sorts are indigenous to the south of Europe, where they are widely distributed; but a few are found in Northern Asia, and on the African shores of the Mediterranean. Most of the species are of free growth in ordinary soils, preferring such as are light and well drained. They are all more or less remarkable for the fugaciousness of their flowers, the corollas in most cases expanding in the morning and falling off at sunset. As others, however, come on in rapid succession and in great abundance, the plants maintain their gay appearance for five or six weeks in summer. This peculiarity is thus prettily alluded to by one of the poets, who says:—

"Yet though the gauzy bells fall fast,
Long ere appears the evening crescent,
Another bloom succeeds the last,
As lovely and as evanescent."

A resinous gum, which exudes from the leaves and young branches of most of the species, notably from those of *C. ladaniferus*, and known in commerce by the name of "labdanum," has a pleasant aromatic fragrance, and is used medicinally in a variety of ways, particularly in plasters, and by perfumers in the preparation of cosmetics. This substance is said to have formerly been gathered from the beards of the "goats, whereon it collected while they browsed on the plants." It is now, however, collected by a leather comb drawn over the branches, to the teeth of which the juice readily adheres, forming an ever-thickening crust, and is easily scraped off with a knife.

The Gum Cistus (*C. ladaniferus*).—This is an evergreen shrub, of about 5 ft. in height, indigenous to Spain and Portugal in mountainous districts. It has been cultivated in our gardens since 1629. The leaves are oblong-lanceolate, smooth, dark green on the upper surface, and slightly hoary below. The flowers are white, with a dark brownish or crimson spot at the base of each petal, appearing in wonderful profusion in June and July. This is one of the most valuable of our wall shrubs, hardy, and of robust growth in any situation where the soil is dry and moderately rich, and, like all its congeners, remarkably patient under the pruning knife. As it flowers, however, from the shoots of the previous year, care should always be taken to thin the branches, rather than indiscriminately cut off all the young wood. The so-called species, *Cyprius*, or *Island of Cyprus Cistus*, differs only from this in its flowers being destitute of the beautiful blotch, so attractive in those of the *Gum Cistus*, and is probably only a variety. It is interesting, however, as a companion plant in collections of wall shrubs.

The Laurel-leaved Cistus (*C. laurifolius*).—A robust evergreen shrub, found naturally over a wide area in Spain and the south of France, where it grows to the height of about 6 ft. It was introduced to our gardens about 1771. The leaves are large, of an ovate-lanceolate form, thick and leathery in texture, smooth dark green above, and covered on the under surface with a minute down. The flowers, which appear in July and August, are pure white, clothed with prominent red bracts, which are very ornamental just before the flowers expand. This is a very free growing species, one of the hardest in cultivation, and very desirable for covering walls. It stands, however, in many districts as a specimen shrub in the open border, when planted in light, well-drained soil.

The Purple-flowered Cistus (*C. purpureus*).—This is a species introduced from the Levant as early as 1659. It is a sub-evergreen, with an erect, bushy habit of growth, from 3 ft. to 4 ft. in height. The leaves are oblong-lanceolate, prominently veined, undulated at the margins, and of a dark green colour. The flowers, which are produced in June and July in great abundance, are reddish-purple, with a bright yellow spot at the base of each petal. The petals are imbricated and erumped. The young branches are covered with a minute pubescence. Though somewhat tender, even on a sheltered wall, this species deserves a trial in any favourable situation, the abundance and brilliancy of its flowers, and its neat, distinct foliage, rendering it quite a feature in a collection of dwarf wall plants. A dry, well-drained soil is essential to its well-being, and a slight covering during the severest of the winter will, in most cases, save it from damage.

The Corbieres Cistus (*C. Corbariensis*).—This distinct-looking dwarf evergreen, which seldom exceeds 3 ft. in height, is found wild over a large area in Spain and the south of France, especially on the mountains of Corbières, from whence it is reported as having been sent to this country in 1656. Its leaves are of an ovate form, wrinkled on both sides, deep green, very glutinous, and fringed. The flowers, which appear in May and June, generally in remarkable profusion, are pure white, tinged at the margins with delicate rose. This is one of the hardiest, as well as the most ornamental, of the genus. It is of very free growth, and well worthy of a prominent place among neat, dwarf, wall evergreens.—“The Gardener.”

PRUNING FOREST TREES.

OLD AND NEW METHODS.

SURE indications of an increased and increasing attention to the growth and management of timber trees are afforded by the anxiety which is now manifested respecting proper methods of thinning and pruning them. At the close of the last and the commencement of the present century great complaint was made about the large quantities of defective Oak timber which was admitted into our

Fig. 1.

doekyards and afterwards rejected as being unfit for use. The demand for Oak timber had for many years been great, and the purveyors found their choice of trees more restricted year after year. The supplies from public and private sources failed to keep pace with the demand. An opinion sprang up that the cause of the evil was the neglect of pruning, and that the rotten branches dying back upon the trunks carried decay to the very hearts of the trees. Many owners of Oak plantations at once commenced a system of pruning which was little better than an indiscriminate lopping of branches; but fearing that too close an application of

the saw would permanently injure the trunk, they cut off branches at distances of 1 ft., 2 ft., and even 3 ft. from it, leaving the stumps to die back, and in some cases intending to cut them off closer at the time of a second pruning. This system of snagg-pruning was soon found not to answer, for a rapid decay of the stump frequently increased the evil which it was meant to cure, and produced rottenness where distortion of the grain would have been the sole evil. The stumps upon which living spray was left, or from which it afterwards sprang out, continued to live on, but they produced irregularities of growth which were almost as objectionable as the dead knots of the decaying branches. An improved method of pruning properly, called foreshortening, first employed by Mr. Billington in the Forest of Dean, was afterwards successfully applied to the hedgerow timber upon the Holkam estate, in Norfolk, by Mr. Blaikie, then the land steward there.

With timely attention no tree should require much pruning after the age of twenty years, and few branches should be cut off after they have attained a diameter of more than 2 in. or 3 in., and consequently have formed red, or heart-wood. But from the results of early neglect, from accidents by winds and other causes, from a desire to open out and extend views, to mitigate the effects of shade, or to improve the form of trees, injured branches frequently require to be removed, and wide-spreading ones of large size to be cut back. From a neglect of timely pruning also arises wind shake in all its

Fig. 2.

forms. Whenever the head of a tree is very unevenly balanced, heavy gusts of wind produce oscillation, resulting in longitudinal rents from the top to nearly the bottom of the trunk, and extending from the pith to the bark. In a similar way is produced cup shake, by which the inner layers of alburnum are separated from the outer, the whole forming a series of tubes which drop apart when the trunk is cut up.

The annexed woodcuts afford illustrations of both the old or snagg method of pruning, and the new or close method:—

Fig. 1, represents the condition of an Oak tree in the twelfth year after pruning. A is a branch only recently cut off at a distance of 9 in. or 10 in. from the trunk; EBB are the stumps of branches which were cut off in a similar manner at the time of the original pruning, and which have now arrived at the stage when they communicate their own rottenness to the organs of the body of the tree; CC are knots, which, though now covered, are producing defects in the timber from the circumstance of their having been cut away 2 in. or 3 in. from the body of the tree. These are the remains of branches of a large size, and the knots continue the disorder in the tree by maintaining the deviation of the tissues and woody fibre.

Fig. 2 represents a branch of large size recently cut off about 8 in. from the trunk, and the surface of which is already splitting from the combined action of the sun and the atmosphere, thus admitting moisture which will rapidly make its way to the heart of the tree. From its having been cut off at so great a distance from the trunk after the bark had become considerably indurated, perfect healing is impossible.

Fig. 3 shows the same stump in the fourth year, when decomposition has made considerable progress, because the bark upon the edges of the cicatrice has not been able to fix itself upon and to over-lap the stump. In consequence of this, the bark itself is falling back from and exposing the wound.

Fig. 3

Fig. 4.

Fig. 5.

Fig. 6.

Fig. 7

Fig. 8.

Fig. 4 represents the same stump in the sixth year after amputation, when decomposition has made still greater progress, and all hopes of arresting it must be abandoned.

Fig. 5 shows its state in the eleventh year, when the rot has formed a gutter, which is extending deeply into the woody tissues, and in which is to be found a considerable quantity of red and fetid water. The stump, being cut obliquely, with its face upwards, takes in water like a sponge, and retains it as in a reservoir. The incessant action of the water renders it impossible to arrest decay, which is consequently rapid.

Fig. 6 is a section of an Oak fifty years old, the branches of which have been cut off at distances of from 8 in. to 12 in. from the trunk, and have since become destroyed by atmospheric influences. AA show the surfaces of the stumps; BB the lips of the cicatrice, which in their efforts to approach each other meet with nothing but decomposed and rotten tissues, instead of sound and solid wood upon which they could fix themselves; consequently they will never unite or cover the wound. CC are rotten masses caused by the decomposition of the woody fibre of the stump, and by the ravages of insects; they stretch deeply into the body of the tree, and will in time extend to the very bottom of the trunk.

Fig. 7 affords an illustration of the newer and more scientific method of pruning, in the second year after the operation has been performed. A fair-sized branch has been removed from an Oak tree from forty to fifty years old. From the cut having been made near the body of the tree, and close to the ringswell, or protuberance of bark and wood which surrounds the base of the branch, natural healing is already far advanced. The surface of the wound is sound and free from all the elements of destruction, which is partly the consequence of its having been dressed at the time of cutting. Whenever a branch of considerable size is cut off near the trunk, the process of healing over is very much facilitated by an application of grafting-clay in a moist state, as wounds from the saw, the pruning chisel, from wheels, or from other causes are healed over much more rapidly when light and air are excluded. Dressings of various kinds, such as hot tar, grafting-wax, &c., have been tried and recommended, but none of them surpass in utility the common clay.

Fig. 8 represents a section of an Oak tree from sixty to eighty years old, in the tenth year after pruning, and upon which perfect healing has taken place, leaving only a slight longitudinal crevice where the lips meet, but which does not extend into the wood. Upon the superincumbent layers of wood when cut up there would appear but a feeble deviation of the fibres. This would be so small as not to interfere with the strength and pliantness of the timber, or cause harm to any part of the woody tissue. Upon recovering from such a wound the tissues could resume their natural and regular direction, the surface of amputation acquiring each year new layers of the white substance between the bark and the wood. After this follows perfect or sound wood, and even the lips of the wound unite and become sound, having retaken the qualities, and almost the appearance, of the original bark, of which it now performs all the usual functions of protection and vitality.

Pluckley, Kent.

A. J. BURROWS.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Profits of Planting Forest Trees.—A Mr. White purchased an estate consisting of high and barren land near Durham, in 1770, for £750. Its extent was upwards of 700 acres. During the first seven years he surrounded it with a strong fence, drained the swampy parts, and planted all except an arable farm of 140 acres. He planted a great variety of trees, Larch and Scotch Pine predominating. At the end of twenty-five years he cleared a portion, and built a commodious house, with proper surroundings. After the first ten or twelve years the plantations began to pay well in thinnings for pit-wood and other purposes. When inquiries were made many years afterwards it was found that the Larch wood alone was making a return of £650 per annum, and for five or six years his son had received more than £400 a-year for his Larch bark, so that the revenue of the entire estate derived from the timber alone was over £1,000 a-year, while the farm, with the recently-formed park, which was let with it, produced a rental of £250 a-year, a result partly attributable to the improvement of the land, caused by the growth of trees, and partly to the shelter afforded to the homestead and farm lands by the standing woods. It is a well-known fact that where Larch is grown in a gravelly soil, upon which there is a fair quantity of vegetable mould, its value is doubled every three years after it is fifteen years old, and every five years after it is five-and-twenty. A valuation of the above woods was made in 1826, when it was estimated that the standing timber was worth the sum of £30,000.—B.

Catalpa speciosa.—This is described in some detail by Dr. Bolle in the *Monatsschrift* for September of the current year. In fact he delivered a lecture before the Horticultural Society of Berlin on this novelty, the report of which occupies nine pages in the publication named. *Catalpa speciosa* was discovered, or distinguished from *C. bignonioides*, by Professor Sargent, of Cambridge, Massachusetts. In the first place we should say that it is stated to be considerably hardier than the *C. bignonioides*, which is no doubt the case, as it inhabits the central States of the Union and extends further northward. Dr. Gray, "Synoptical Flora of North America," vol. ii., part 1, p. 320, gives the habitat and distribution of the old species as:—"River banks, South Illinois to Georgia, West Florida, and Louisiana." *C. speciosa* is known to occur in the States of Kentucky, Tennessee, Missouri, Ohio, Illinois, and Indiana. The distinctive characters of this species or variety are the more gradually tapering leaves, larger white flowers, appearing in Ohio during the first fortnight in June; a larger and more compressed seed-vessel, often 16 in. to 20 in. long; shorter, broader seeds, with wings of equal width at their rounded ends. The bark is also of a darker hue, and more deeply furrowed, and the wood is considerably heavier. The tree is taller and handsomer than *C. bignonioides*, and it bears the severest winters without injury up to 42° N. lat. We (*Gardeners' Chronicle*) have examined a number of dried specimens of *Catalpa* from various localities in North America, but we have seen none which could belong to this new species or variety. Professor Sargent has sent seeds of *C. speciosa* to Dr. Bolle, and we daresay it has found its way to this country ere this.

Tree Felling.—Notwithstanding the examples of axe-felling timber which have been set in high quarters, we cannot but look upon the method as a clumsy one at the best, and at the same time both wasteful and slow. As an exercise it may prove excellent, and, looking at it from the woodman's point of view, "the more hewing the more chips." But felling with the cross-cut saw is not only more expeditious, but also more workmanlike, as an experienced woodman can by this method throw his tree within a few feet of the spot which he selects for it. By fixing on his site, and cutting his triangular notch, called the fall, in the proper direction, hewing down the spurs on a level with the surface of the ground to form a plane for his saw to work upon, and driving his wedges well up, according to the balance of the head of the tree as his saw approaches the fall, the work is performed with the greatest economy of both time and labour, and with the least injury to the rest of the trees.—A. J. B.

Sizes and Ages of Oaks.—Mr. Basil Edwards states that he has received notices and descriptions of several very fine Oaks in answer to his enquiry about large Oaks in the *Times*. Of these the Cowthorpe Oak, Yorkshire, seems to be regarded as the largest Oak in Britain. Its measurements, as furnished by the Rector of Cowthorpe, are—at the ground, 55 ft. 6 in.; 5 ft. above the ground, 38 ft. 4½ in. Those of the Newland Oak are—at the ground, 46 ft., and 5 ft. from the ground its girth is 47 ft. 6 in. Opinions may differ as to which of these fine trees is the larger, but a tree which measures 47 ft. 6 in. at a height of 5 ft. from the ground is surely a larger tree than one which measures even 56 ft. close to the ground, where it is unavoidable to take the root buttresses or some part of them into the measurement. It may be interesting to know that the Newland Oak, which from the above measurement seems to be the largest in the country, is mentioned in Domesday Book as a large tree in the new lands at that time cleared. This, allowing for the slow growth of Oaks, will give it an age probably not inferior to its Yorkshire or any other competitor.—*Times*.

Advantages of Large Plantations.—In the very hardest frosts the ground is seldom frozen in the middle of a large and well-set coppice of six years' growth and upwards. Even in that bleak and terribly cold country, New Brunswick, where the frost comes about the 7th of November, freezes the River St. John (a mile wide) over in one night, so that men walk across in the morning—where in the open lands the frost goes 4 ft. down into the solid ground, if you go half a mile into the woods you are in a mild and pleasant climate. I have scores of times gone to the edges of the woods wrapped up in flannels, blankets, and furs, and when I got in reduced my dress very nearly to an English one.—C.

A Hint for Planters of Exposed Sites.—Trees have their feelings; and what must inevitably be the consequence of taking a young Oak from a warm coppice and planting it on a naked common? Plantations in these situations are useful, ornamental, and therefore highly praiseworthy, but then the trees should be raised for the purpose—raised and managed with a view to their destination. The young trees should be moved twice at least, and they should at the last removal be placed at a good distance from each other.—COBBETT.

THE FRUIT GARDEN.

GRAPES AND THEIR CLASSIFICATION.

By A. F. BARRON.

THE varieties of Grapes are so numerous, and a large proportion of them nearly, if not quite, unknown, and so unsuitable for cultivation in this country—being mainly used for wine-making—that it is not desirable, even were it possible, to attempt in this place a complete enumeration of them. We shall rather confine ourselves to noticing such of the different varieties that are or have been grown in this country, as are distinct, or have some supposed merit attached to them.

In a broad sense, the cultivated Grapes are divisible into two great families. The European, including all the varieties of Grapes of the Old World; the American, including those belonging to the New World. These two series of Grapes are very distinct, not only in constitution, but also in foliage and fruit; but as the American Vines are not cultivated in this country for their fruit, if we except the Strawberry Grape and an occasional plant of the Catawba or Isabella, it will be unnecessary to allude to them further.

There has been no very definite classification of Grapes yet adopted, although the desirability of some simple and popular way of grouping the different varieties, whereby those who have only a limited knowledge may comprehend something of the nature or character of the variety named, is self-evident, and the want of it has long been felt. Thus, for example the terms Muscat and Sweetwater are pretty well understood, as conveying a knowledge of the flavour and general character of the respective varieties to which they are attached; and it is by an elaboration of this idea that we propose to arrange them into three great classes or sections—

Firstly, by the flavour of the fruit—

1. Sweetwater Grapes
2. Muscat Grapes
3. Vinous Grapes

Secondly, by the colour of the fruit—

- A. Black or purple
- B. White, green, or yellow
- C. Red or tawny

Thirdly, by the shape of the fruit—

- * Oval
- ** Round

making in all eighteen well-marked groups or subdivisions. In this way, one would be enabled to speak of the Chasselas Musqué, for example, as a round, white, Muscat Grape; of the Black Hamburgh, as an oval, black, Sweetwater Grape; and of the Gros Colman, as a round, black, Vinous Grape, &c.

European Grapes.

Class I.—Sweetwater Grapes.

Varieties with sweet, sugary, or saccharine flavour, the juice thin, but pleasant, varying in sweetness; skin generally thin and tender. They are mostly early varieties and ripen freely. Those termed Muscadines are here included, as well as the greater portion of what the French term Chasselas:

A.—Berries Black or Purple.

* Oval.

- | | |
|----------------------------------|-------------------|
| 1. Black Hamburgh or Frankenthal | 3. Black Prince |
| 2. Black Monukka | 4. Eillade Noire |
| | 5. Trentham Black |

** Round.

- | | |
|--------------------|------------------------|
| 6. Black Bordeaux | 9. Black Corinth |
| 7. Black July | 10. Miller's Burgundy |
| 8. Black Muscadine | 11. Mill Hill Hamburgh |

B.—Berries White, Green, or Yellow.

* Oval.

- | | |
|-----------------------------|--------------------------|
| 12. Bicane | 16. Golden Champion |
| 13. Cabral | 17. Madeleine Royale |
| 14. Foster's White Seedling | 18. Scotch White Cluster |
| 15. Grove-end Sweetwater | 19. White Romain |

** Round.

- | | |
|---------------------------|-----------------------------|
| 20. Buckland Sweetwater | 28. Golden Hamburgh |
| 21. Chasselas de Florence | 29. Gros Romain |
| 22. Chasselas Royal | 30. Pitmaston White Cluster |
| 23. Chaptal | 31. Prolific Sweetwater |
| 24. Ciotat | 32. Royal Muscadine |
| 25. Duke of Buccleuch | 33. Stillward's Sweetwater |
| 26. Dutch Sweetwater | 34. White Frankenthal |
| 27. General della Marmora | |

C.—Berries Red, Tawny, or Variegated.

* Oval.

- | | |
|--------------------|-----------------------|
| 35. Abbee | |
| | ** Round. |
| 36. Aleppo | 39. Gromier du Cantal |
| 37. Chasselas Rose | 40. Lombardy |
| 38. De Candolle | 41. Tokai des Jardins |

Class II.—Muscat Grapes.

Varieties with musky or perfumed flavour, generally with firm flesh. The larger varieties, as a rule, require a warmer temperature to ripen them than the Sweetwaters. The Frontignans are included amongst the Muscats:

A.—Berries Black or Purple.

* Oval.

- | | |
|-----------------------------|---------------------|
| 42. Ingram's Hardy Prolific | 44. Muscat Hamburgh |
| 43. Madresfield Court | 45. Mrs. Pince |

** Round.

- | | |
|-----------------------|-------------------------|
| 46. Angers Frontignan | 50. Jura Frontignan |
| 47. August Frontignan | 51. Muscat de Lierval |
| 48. Black Frontignan | 52. Meurthe Frontignan |
| 49. July Frontignan | 53. Sarbelle Frontignan |

B.—Berries White, Green, or Yellow.

* Oval.

- | | |
|--------------------------|--------------------------|
| 54. Ascot Citronnelle | 57. Muscat of Alexandria |
| 55. Canon Hall Muscat | 58. Muscat Bifère |
| 56. Ferdinand de Lesseps | 59. St. Laurent |

** Round.

- | | |
|-----------------------------|------------------------|
| 60. Ascot Frontignan | 66. Mrs. Pearson |
| 61. Auvergne Frontignan | 67. Ottonel |
| 62. Chasselas Musqué | 68. Saumur Frontignan |
| 63. Dr. Hogg | 69. Trovère Frontignan |
| 64. Duchess of Buccleuch | 70. White Frontignan |
| 65. Early Silver Frontignan | |

C.—Berries Red or Tawny.

** Round.

- | | |
|------------------------|---------------------|
| 71. Grizzly Frontignan | 73. Muscat Champion |
| 72. Madeira Frontignan | |

Class III.—Vinous Grapes.

Varieties with a strong vinous or somewhat harsh flavour, and thick skin. They mostly require a considerable amount of heat and time to ripen them. Generally termed late Grapes.

A.—Berries Black or Purple.

* Oval.

- | | |
|----------------------|------------------------|
| 74. Alicante | 78. Morocco Prince |
| 75. Alnwick Seedling | 79. Royal Ascot |
| 76. Black Morocco | 80. West's St. Peter's |
| 77. Gros Maroc | |

** Round.

- | | |
|--------------------|---------------------------|
| 81. Aramon | 84. Gros Colman |
| 82. Espiran | 85. Gros Guillaume |
| 83. Dutch Hamburgh | 86. Lady Downe's Seedling |

B.—Berries White or Yellow.

* Oval.

- | | |
|--------------------|-------------------|
| 87. Chavoush | 91. Trebbiano |
| 88. Golden Queen | 92. Waltham Cross |
| 89. Royal Vineyard | 93. White Lisbon |
| 90. Syrian | 94. White Tokay |

** Round.

- | | |
|---------------------------------|----------------|
| 95. Raisin de Calabre | 97. White Nice |
| 96. White Lady Downe's Seedling | |

American Grapes.

These are all more or less perfumed, and have a peculiar foxy taste, with gelatinous flesh.

A.—Berries Black or Purple.

* Round.

- | | |
|-------------|----------------|
| 98. Catawba | 99. Strawberry |
|-------------|----------------|

This synopsis of select varieties includes all the Grapes at present known which we think most deserving of attention on some ground or other, though for general utility the number might be reduced within very narrow limits.—*Florist and Pomologist.*

The Sub-tropical Garden.—A new edition of this book has been published by Mr. Murray.

COLOUR IN GRAPES.

JUDGING from what one reads on this subject, much importance seems to be attached to admitting air to the Vine, particularly when the fruit begins to colour. No doubt ventilation is necessary at all times, but the colouring process does not begin when the colour commences to be visible, and no kind of treatment that can be adopted will make Grapes colour after that period if the conditions of the Vines previously and the treatment have not been such as to promote a good finish. The conditions under which Grapes will colour perfectly sometimes are puzzling. As good samples as ever I saw were ripened at the new year, and at periods between that and April. Mr. Michie, an amateur Grape grower at North Berwick, ripened crops of Black Hamburg at the new year several years in succession, and they were exceedingly well finished; and were sold, I believe, in London for 30s. per lb. I have had Black Hamburgs, from pot Vines here, ripe early in April that were as black as jet, and covered with as deep a bloom as ever I saw on Grapes. Yet the Vines that produced them were not extra strong nor the bunches or berries extra large. The finish and flavour were the most remarkable things about them. In neither of the above cases could the colour be said to be due to the free ventilation, for little air could be admitted at the dead season of the year. On the other hand, the worst-coloured Grapes I have ever seen were ripened at the most favourable season of the year, viz., after midsummer.

My own impression is that anything that tends to produce good foliage on the Vine, and of a dark green colour, and to preserve the same in good condition upon the Vines till the fruit is ripe, will also produce well-coloured Grapes and flavour of the highest excellence. Vines with thin pale green foliage, produce fruit of the same shade at an early stage, and such almost invariably finish badly at the end, and the berries are fleshless and insipid or sour. The colour of Grapes does not lie altogether in the skin, as some imagine, and hence it is not to be put on by external agency, as, for example, by the freer admission of air after the season of growth is nearly completed. The skin of a well-coloured Grape looks red after it is peeled off the berry, and it will be found that a good deal of the colouring matter lies on the surface of the flesh, and always most plentifully near the point of the berry and least near the foot-stalk. It will be observed, too, as a rule, that the firmest-fleshed fruit looks the blackest—the opaque body no doubt helping to deepen the colour.

But the most curious thing about colour in Grapes is that, no matter how deep it may be when the Grapes ripen, it disappears to a great extent if they are allowed to hang long upon the Vines. This is especially so in the case of the Black Hamburg, which turns to a foxy-red colour after a while. A correspondent of THE GARDEN has drawn attention to this fact before. It is pretty certain that over-cropping will cause the colour to fail, but this is not always the cause, as is proved by every-day's experience. Still, it may be asserted as a general rule that well-ripened wood and good foliage carried till the end of the season, in conjunction with moderate crops, will ensure perfect colour in the great majority of cases. J. S. W.

CROPPING PEACH AND NECTARINE TREES.

MR. COWBURN, in saying (p. 372) that one Peach to the square foot cannot be called a crop is, to a certain extent, right; still, if the crop was regular and the fruit very large, any one might be satisfied with such a result; but for crops of fair-sized fruit one to the square foot is not a sufficient or remunerative crop for the Peach, and it is less so for the Nectarine. Indeed, the system of reckoning the crop by the square foot or superficial area of whatever extent, or at least of thinning it out on that principle, is a wrong one, and I do not suppose that many Peach growers follow it, for it soon becomes evident to the practitioner that by such a method of thinning the energies of the tree would be very unequally taxed. For example, some strong shoots will bear a good fruit every 6 in. of their length, and be all the better of being taxed to that extent; while on other and weaker shoots it would be unwise to have more than one, and on some none should be allowed to grow. During the past year we had as many as six fruits of the Victoria Nectarine on strong shoots about 2 ft. long, and some shorter shoots bore at even a considerably heavier rate; but on the average I daresay a good-sized fruit every half square foot, or a little less, was about the crop. Shoots lying contiguous and cropped at that rate looked very heavily laden, but they could well bear it. We have trees (Nectarines) here that have been cropped at about the above rate for more than a dozen years without showing the least signs of distress, though they have not missed a crop during that period. Still, much depends upon the health of the tree and the variety.

There can be no doubt that heavy cropping is as injurious to the Peach as to the Vine, and weak trees should be cropped only lightly. In some cases, indeed, we have seen feeble trees greatly

benefited by being denuded of their crops entirely for a year when restorative measures were being taken. Such strong-growing Peaches as the Grosse Mignonne and Walburton Admirable, and Nectarines like the Victoria, will bear cropping at a heavier rate than the Royal George Peach or Downton Nectarine respectively, which are less vigorous growers. No rule can be laid down in the matter, in fact, that would apply to all cases; the quantity of fruit to leave must be a question of judgment, but we would prefer to err on the safe side, and not over-crop; but at the same time we cannot say that we ever saw a crop thinned to one fruit for each square foot where the cultivator had the option of leaving more. On a moderately strong shoot, about 9 in. or 1 ft. long, on a thinly trained tree, we should, perhaps, leave one good fruit; but on strong young limbs, inclined to be gross, we should not hesitate to leave a fruit every 3 in. or 4 in. if they would stay on. I have often cropped such strong branches as heavily as this, but the weaker shoots near the base of the tree were spared proportionately. It should never be forgotten, however, that the early and free thinning of the fruit is a great aid to the maturation of a fine crop, and I attach far more importance to thinning freely before the fruit is stoned than afterwards. Strong young trees do not exhibit much sign of the strain put upon them at the stoning period, but they do feel it sensibly, nevertheless, as any close observer may see, and all vigour spent then upon fruit that is not intended to be left is so much lost to that which remains. It is caution, I am aware, that induces cultivators to delay final thinning till after the stoning period, and I confess I do not like to thin down finally till after that period; but at the same time, I leave a very slender margin in the case of healthy free-bearing trees.

Some trees in certain soils set a disproportionate quantity of fruit-buds and few leaf-buds, particularly the Noblesse Peach, but all such should have their fruit-buds thinned before forcing begins, taking away the smallest and puniest-looking of the group, and which is usually the middle one, that should have been a leaf-bud. Then, as soon as the fruit is set, the most of it should be rubbed off, leaving the largest and most prominent, and, just before stoning begins, the trees should be gone over again and thinned down to about a crop. J. S. W.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Training Peach Trees on the Extension System.—I have to thank "J. S. W." for his explanation (p. 386) respecting this system, but I cannot see why, in support of his opinion, he should quote from the "Gardener's Assistant" the opposite method in its extremity, in order to show deformity, abortion, and premature decay, for he will find, on referring to p. 372, that it is what I there term barbarous pruning, which, together with the so-called extension system, I equally deprecate. A line drawn somewhere between the two extremes I have always found to be best. For proof let me refer to No. 404, p. 148, of THE GARDEN, where he will find that the Peach and Nectarine trees here bore ten good fruit throughout to the square foot, and my opinion is that unless the knife is judiciously applied to the weaker shoots when at rest it is impossible for them to maintain their own with the more robust in the coming season's contest, or the trees to carry crops year after year such as those to which I have referred. Pears, Apples, *Cratægus pyracantha*, &c., do not come under the same head, each requiring separate or different treatment. A good gardener, in order to secure extraordinary results, must, like a good doctor, possess a full knowledge of the nature, constitution, and location in which his trees are placed, knowledge not to be acquired, in either case, by theoretical teaching.—J. COWBURN.

Inarching Grape Vines.—Amateurs often have Vines that are unsuitable for their purpose, therefore how best and quickest to obtain better kinds, and at the least cost, is to them a question of importance; but by far the greatest consideration lies in discovering a way to obtain a good crop in the shortest time. I have just seen the result of an experiment carried out by Mr. Wincote, of the Grove Vineyard, Feltham, that shows forcibly the value of inarching new or other kinds of Grapes on old stems. At one end of a long lean-to range of glass of over 200 ft. run, and which has hitherto been cropped two-thirds with Muscat of Alexandria, the rest being Lady Downes, Barbarossa, and Gros Colman, all the coloured kinds were last spring twelvemonth inarched with pot plants of the Muscat. The take was exceptionally good, but a couple were, unfortunately, broken off during the summer. The old Vines carried as usual their crop of fruit, and these, early in the winter, were cut clean away to allow the inarched rods to come up. The result in growth has been almost astonishing, the new rods being as stout as broomsticks, and ripe to the top of the house; whilst next the failures extra rods have been carried up of great size also. Further,

several are carrying small bunches of fine berries. The new top growth, having such immense root power below, has made about three times the growth that would have been obtained from newly-planted Vines, for which also a new border must have been made.—A. D.

Gilbert's Netted Victory Melon.—Although grown as a late crop, with several other approved sorts, this has been pronounced by good judges to be by far the best Melon of the year as regards flavour.—J. G.

Orchard Trees Dry at the Root.—In grubbing up some large Pear trees lately, I was surprised to find the soil beneath and about their roots as hard and dry as if we had had a tropical summer instead of one characterised by storm and flood. This is doubtless attributable to the rain being held in suspension by the foliage of the trees and long herbage underneath them, the moist season having induced an unusually heavy crop of rank Grass. We may therefore find after all that exceptionally wet seasons leave some benefit behind to make up for the temporary discomfort which they occasion. We have heard dismal forebodings as to the wood of fruit-bearing trees not ripening, but as the leaves are falling quite as early as in ordinary years, I am induced to think that trees, shrubs, and bushes will at least be benefited rather than harmed by the amount of rain that has fallen. Our soil is rather heavy, and retains moisture a long time; therefore, what would benefit us would, in this respect, be even more beneficial to light porous soils, where there is no doubt trees often suffer from dryness at the root more than people are generally aware of.—J. Groom, *Linton*.
